Rationale: Vomiting causes the loss of hydrochloric acid and subsequent metabolic alkalosis. Metabolic acidosis would occur in a child experiencing diarrhea because of the loss of bicarbonate. Diarrhea might or might not accompany vomiting. Hyperactive bowel sounds are not associated with vomiting.
Test-Taking Strategy: Focus on the **subject,** complications related to vomiting. Recalling that gastric fluids are acidic and that the loss of these fluids leads to alkalosis will assist you in answering the question. No data in the question support options 1 and 4.
Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. p. 989.

6. *Answer:* 3
Rationale: Imperforate anus is the incomplete development or absence of the anus in its normal position in the perineum. During the newborn assessment, this defect would be identified easily on sight. However, a rectal thermometer or tube may be necessary to determine patency if meconium is not passed in the first 24 hours after birth. Other assessment findings include absence or stenosis of the anal rectal canal, presence of an anal membrane, and an external fistula to the perineum. Options 1, 2, and 4 are findings noted in intussusception.
Test-Taking Strategy: Note the **subject,** manifestations of imperforate anus. Use the definition of the word *imperforate* to assist in answering this question. This would direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 880.

7. *Answer:* 2
Rationale: In pyloric stenosis, hypertrophy of the circular muscles of the pylorus causes narrowing of the pyloric canal between the stomach and the duodenum. Clinical manifestations of pyloric stenosis include projectile vomiting, irritability, hunger and crying, constipation, and signs of dehydration, including a decrease in urine output.
Test-Taking Strategy: Focus on the **subject,** the manifestations of pyloric stenosis. Considering the anatomical location of this disorder and its potential effects will assist in eliminating options 1 and 3. Thinking about the pathophysiology of the disorder and recalling that a major clinical manifestation is projectile vomiting will assist in directing you to the correct option from those remaining.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 859.

8. *Answer:* 1
Rationale: Celiac disease also is known as *gluten enteropathy* or *celiac sprue* and refers to intolerance to gluten, the protein component of wheat, barley, rye, and oats. The important factor to remember is that all wheat, rye, barley, and oats need to be eliminated from the diet and replaced with corn, rice, or millet. Vitamin supplements—especially the fat-soluble vitamins, iron, and folic acid—may be needed to correct deficiencies. Dietary restrictions are likely to be lifelong.
Test-Taking Strategy: Focus on the **subject,** home care instructions for the child with celiac disease. Recalling that corn, rice, and millet are food substitutes in this disease will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 862-863.

9. *Answer:* 4
Rationale: Intussusception is a telescoping of one portion of the bowel into another. The condition results in an obstruction to the passage of intestinal contents. A child with intussusception typically has severe abdominal pain that is crampy and intermittent, causing the child to draw in the knees to the chest. Vomiting may be present, but is not projectile. Bright red blood and mucus are passed through the rectum and commonly are described as currant jelly–like stools. Watery diarrhea and ribbon-like stools are not manifestations of this disorder.
Test-Taking Strategy: Focus on the **subject,** the manifestations of intussusception. Think about the pathophysiology associated with this condition. Recalling that a classic manifestation is currant jelly–like stools will assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 860-861.

10. *Answer:* 1, 2, 5
Rationale: Hepatitis is an acute or chronic inflammation of the liver that may be caused by a virus, a medication reaction, or another disease process. Because hepatitis can be viral, standard precautions need to be instituted in the hospital. The child would be discouraged from sharing toys, so playtime in the playroom with other children is not part of the plan of care. The child will be allowed to return to school 1 week after the onset of jaundice, so indefinite homeschooling would not need to be arranged. Jaundice is an expected finding with hepatitis and would not warrant notification of the PHCP. Provision of a low-fat, well-balanced diet is recommended. Parents are cautioned about administering any medication to the child, because normal doses of many medications may become dangerous, owing to the liver's inability to detoxify and excrete them. Handwashing is the most effective measure for control of hepatitis in any setting, and effective handwashing can prevent the immunocompromised child from contracting an opportunistic type of infection.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Focus on the **subject,** care for a child with hepatitis. Thinking about the pathophysiology associated with hepatitis and the method of transmission will assist you in answering the question. Because the infection can be transmitted to others, playing with other children in the playroom is an inappropriate intervention. Since jaundice is an expected finding, notifying the PHCP is unnecessary. Planning for an indefinite period of homeschooling is not necessary.

CHAPTER 35

Eye, Ear, and Throat Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

PRIORITY CONCEPTS Safety; Sensory Perception

I. Strabismus

A. Description
1. Called "squint" or "cross-eye"
2. Condition in which the eyes are not aligned because of lack of coordination of the extraocular muscles
3. It most often results from muscle imbalance or paralysis of extraocular muscles, but it also may result from a congenital defect or poor vision.
4. Amblyopia (reduced visual acuity) may occur if not treated early, because the brain receives two messages as a result of the nonparallel visual axes.
5. To assess condition: six cardinal positions of gaze, corneal light reflex, and the cover-uncover test
6. Permanent loss of vision can occur if not treated early.
7. This condition, considered a normal finding in a young infant, would not be present after about age 4 months.
8. Treatment of the condition depends on the cause.

B. Assessment
1. Crossed eyes
2. Squinting; tilts the head or closes one eye to see
3. Loss of binocular vision
4. Impairment of depth perception
5. Frequent headaches
6. Diplopia; photophobia

C. Interventions
1. Corrective lenses may be indicated.
2. Instruct the parents regarding patching (occlusion therapy) of the "good" eye to strengthen the weak eye.
3. Prepare for surgery to realign the weak muscles as prescribed if nonsurgical interventions are unsuccessful.
4. Instruct the parents about the need for follow-up visits.

II. Conjunctivitis

A. Description
1. Also known as "pink eye"; an inflammation of the conjunctiva
2. Conjunctivitis usually is caused by allergy, infection, or trauma.
3. Types include viral, bacterial, or allergic; bacterial or viral conjunctivitis is extremely contagious.

B. Assessment
1. Itching, burning, or scratchy eyelids
2. Redness
3. Edema
4. Discharge

! Chlamydial conjunctivitis is rare in older children; if diagnosed in a child who is not sexually active, the child needs to be assessed for possible sexual abuse.

C. Interventions
1. Viral conjunctivitis.
   a. The infection will usually resolve in 7 to 14 days; in some cases it can take 2 to 3 weeks or more to resolve.
   b. Antiviral medication may be prescribed to treat more serious forms of conjunctivitis, such as those caused by herpes simplex virus or varicella zoster virus; antibiotics are not effective against viruses.

Telegram & Insta: NCLEX_RN_Edu

2. Bacterial conjunctivitis
   a. Mild cases may improve without antibiotic treatment.
   b. An antibiotic, usually prescribed topically as eye drops or ointment, may be prescribed to shorten the length of infection, reduce complications, and reduce the spread to others.
3. Allergic conjunctivitis
   a. Removing the allergen from the environment often improves the condition.
   b. Allergy medications and eye drops such as topical antihistamine and vasoconstrictors may be prescribed.
4. General interventions
   a. The primary health care provider (PHCP) needs to be consulted regarding going to school and contact with others.
   b. Instruct the child and parents about the administration of the prescribed medications.
   c. The tip of the eye drop or ointment delivery device cannot touch the eye, eyelid, or lashes.
   d. Instruct in infection control measures, such as good handwashing and not sharing towels and washcloths.
   e. Instruct the child to avoid rubbing the eye to prevent injury.
   f. Instruct a child who is wearing contact lenses to discontinue wearing them and to obtain new lenses to eliminate the chance of reinfection that can occur from the use of the old lenses.
   g. Instruct an adolescent that eye makeup needs to be discarded and replaced.
   h. For additional information, refer to the Centers for Disease Control and Prevention at https://www.cdc.gov/conjunctivitis/index.html

III. Otitis Media

A. Description
   1. An inflammatory disorder usually caused by an infection of the middle ear, occurring as a result of a blocked eustachian tube, which prevents normal drainage; can be acute or chronic
   2. Otitis media is a common complication of an acute respiratory infection (most commonly from respiratory syncytial virus, influenza, or group A streptococcus).
   3. Infants and children have eustachian tubes that are shorter, wider, and straighter, which makes them more prone to otitis media.

B. Prevention
   1. Feed infants in an upright position to prevent reflux.
   2. Maintain routine immunizations.
   3. Encourage breast-feeding/chest-feeding for at least the first 6 months of life.
   4. Avoid exposure to tobacco smoke and allergens.

C. Assessment
   1. Fever
   2. Acute onset of ear pain
   3. Crying, irritability, lethargy
   4. Loss of appetite
   5. Rolling of head from side to side
   6. Pulling on or rubbing the ear
   7. Purulent ear drainage may be present
   8. Red, opaque, bulging, immobile tympanic membrane on otoscopic examination
   9. Signs of hearing loss (indicative of chronic otitis media)

D. Interventions
   1. Encourage fluid intake (may be difficult if the child is in pain).
   2. Instruct the child to avoid chewing as much as possible during the acute period, because chewing increases pain.
   3. Provide local heat or cold as prescribed to relieve discomfort, and have the child lie with the affected ear down.
   4. Instruct the parents in the appropriate procedure to clean drainage from the external ear canal with sterile swabs or gauze; frequent cleansing and the application of moisture barriers may be prescribed to prevent ear excoriation from the drainage.
   5. Instruct the parents in the administration of analgesics or antipyretics such as acetaminophen or ibuprofen as prescribed to decrease fever and pain.
   6. Instruct the parents in the administration of antibiotics if prescribed, emphasizing that the prescribed period of administration is necessary to eliminate infective organisms.
   7. In healthy infants older than 6 months and in children, careful use of antibiotics is recommended because of concerns about medication-resistant *Streptococcus pneumoniae;* usually, waiting up to 72 hours for spontaneous resolution is a safe and appropriate management of acute otitis media.
   8. Instruct the parents that screening for hearing loss may be necessary.
   9. Instruct the parents about the procedure for administering ear medications such as topical pain-relief drops, if prescribed.

E. Otitis Externa
   1. Description: Inflammation of the external auditory canal, which can occur with or without infection; also known as "swimmer's ear"
   2. Assessment
      a. Rapid onset of symptoms within 48 hours; symptoms include otalgia, pruritus, fullness, drainage, and impaired hearing.
      b. A low-grade fever may be present.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

c. Tenderness on manipulation of the pinna and tragus is noted on physical exam.
d. May have regional lymphadenopathy.

3. Interventions: Treatment is indicated with topical antibiotics and may include neomycin with or without polymyxin B or a fluoroquinolone preparation.

⚠ To administer ear medications in a child younger than 3 years, pull the earlobe down and back. In a child older than 3 years, pull the pinna up and back.

F. Myringotomy
1. Description
a. A surgical incision into the tympanic membrane to provide drainage of the purulent middle ear fluid; may be done by a laser-assisted procedure
b. Tympanoplasty tubes, which are small cylinder-shaped tubes, may be inserted into the middle ear to allow continued drainage and to equalize pressure and allow ventilation of the middle ear.
2. Postoperative interventions
a. Instruct the parents and child to keep the ears dry.
b. The child needs to wear earplugs while bathing, shampooing, and swimming (diving and submerging under water are not allowed).
c. Parents can administer an analgesic such as acetaminophen or ibuprofen to relieve discomfort after insertion of tympanoplasty tubes.
d. Parents need to be taught that the child should not blow the nose for 7 to 10 days after surgery.
e. Instruct the parents that the tubes usually fall out spontaneously in 6-12 months, it is not an emergency, but the PHCP needs to be notified; inform the parents of the appearance of the tubes (tiny, white, spool-shaped tubes).

IV. Tonsillitis and Adenoiditis

A. Description
1. *Tonsillitis* refers to inflammation and infection of the tonsils, which is lymphoid tissue located in the pharynx (Fig. 35.1).
2. *Adenoiditis* refers to inflammation and infection of the adenoids (pharyngeal tonsils), located on the posterior wall of the nasopharynx.
3. Enlarged tonsils and adenoids may lead to an obstructive sleep apnea in children, manifested by snoring and periods of sudden waking and fragmented sleep; a polysomnography and referral to an ear, nose, and throat specialist may be needed.
4. Can be the result of a viral, bacterial, or fungal infection. Group A streptococcus ("strep throat") is a common bacterial infection of the oropharynx, particularly in children, which can result in streptococcal toxic shock syndrome. Mononucleosis is another possible cause of tonsillitis and adenoiditis.
5. Tonsillectomy (surgical removal of the tonsils) and adenoidectomy (surgical removal of the adenoids) may be necessary, depending on the number of infections per year as well as signs of obstructive respiratory disturbance.

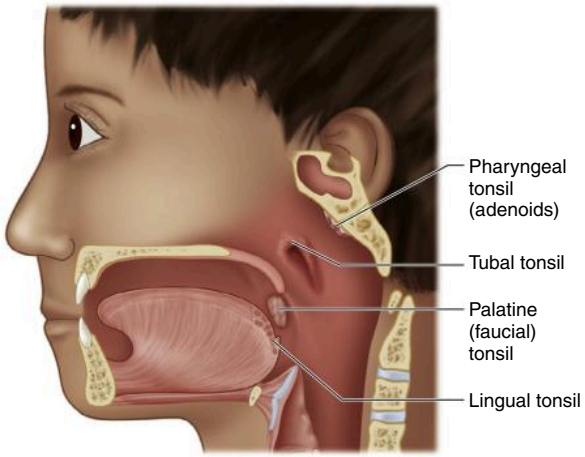

FIG. 35.1 Location of various tonsillar masses.

B. Assessment
1. Persistent or recurrent sore throat
2. Enlarged, bright red tonsils that may be covered with white exudate
3. Difficulty in swallowing
4. Mouth breathing and an unpleasant mouth odor
5. Fever
6. Cough
7. Enlarged adenoids may cause nasal quality of speech, mouth breathing, hearing difficulty, snoring, or obstructive sleep apnea.

C. Preoperative interventions
1. Assess for signs of active infection.
2. Assess bleeding and clotting studies, because the throat is vascular.
3. Assess for any loose teeth to decrease the risk of aspiration during surgery.
4. Prepare the child for a sore throat postoperatively, and inform the child that they will need to drink liquids.

D. Interventions postoperatively
1. Position the child prone or side-lying to facilitate drainage.
2. Have suction equipment available, but do not suction unless there is an airway obstruction.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Monitor for signs of bleeding (frequent swallowing/clearing of throat may indicate bleeding); if bleeding occurs, turn the child to the side and notify the PHCP.
4. Discourage coughing, clearing the throat, or nose blowing to prevent bleeding.
5. Provide an ice collar or analgesics (rectally or intravenously) for discomfort.
6. Administer antiemetics to prevent vomiting if prescribed.
7. Provide clear, cool, noncitrus, and noncarbonated fluids (crushed ice, ice pops).
8. Avoid red, purple, or brown liquids, which simulate the appearance of blood if the child vomits.
9. Avoid milk products such as milk, ice cream, and pudding initially because they coat the throat, causing the child to cough to clear the throat.
10. Soft foods may be prescribed 1 to 2 days postoperatively.
11. Do not give the child any straws, forks, or sharp objects that can be put into the mouth.
12. Mouth odor, slight ear pain, and a low-grade fever may occur for a few days postoperatively, but the parents need to be instructed to notify the PHCP if bleeding, persistent earache, or fever occurs.
13. Instruct the parents to keep the child away from crowds until healing has occurred; usually the child is able to resume normal activities 1 to 2 weeks postoperatively.

V. Epistaxis (Nosebleed)

A. Description
1. The nose, especially the septum, is a highly vascular structure, and bleeding usually results from direct trauma, foreign bodies, and nose picking or from mucosal inflammation.
2. Recurrent epistaxis and severe bleeding may indicate an underlying disease.

B. Interventions (see Clinical Judgment: Take Action Box)

VI. Allergic Rhinitis

A. Description: a condition in which children are sensitized to environmental allergens

B. Assessment
1. Itchy and watery eyes, runny nose, itchy throat
2. May be a family history of atopic disease
3. Dark circles under the eyes, cobblestoning of the conjunctiva, pale nasal mucosa, clear nasal drainage, nasal polyps, fluid in the middle ear, cobblestoning of the posterior pharynx, wheezes, rhonchi, eczema, hives, angioedema

C. Interventions
1. Children with allergic rhinitis need to be tested for environmental allergies, food allergies, atopic dermatitis, and asthma.
2. Avoidance of triggers; administration of prescribed antihistamines, nasal corticosteroids, inhalers

CLINICAL JUDGMENT: TAKE ACTION

A nurse is attending a school-aged child's soccer game when a child is hit in the nose area with the soccer ball and is bleeding from the nose. The nurse takes the following actions to stop the bleeding:

- Approaches the child calmly
- Remains calm and keeps the child calm and quiet
- Assists the child to sit up and lean forward
- Applies continuous pressure to the nose with the thumb and forefinger for at least 10 minutes
- Inserts cotton or wadded tissue into each nostril, and applies ice or a cold cloth to the bridge of the nose if bleeding persists
- Arranges for transport of the child to the emergency department if the bleeding cannot be controlled; packing or cauterization of the bleeding vessel may be indicated

PRACTICE QUESTIONS

1. After a tonsillectomy, a child begins to vomit bright red blood. The nurse would take which **initial** action?
   1. Turn the child to the side.
   2. Administer the prescribed antiemetic.
   3. Maintain NPO (nothing by mouth) status.
   4. Notify the primary health care provider (PHCP).

2. The parent of a 6-year-old child arrives at a clinic because the child has been experiencing itchy, red, and swollen eyes. The nurse notes a discharge from the eyes and sends a culture to the laboratory for analysis. Chlamydial conjunctivitis is diagnosed. On the basis of this diagnosis, the nurse determines that which requires further investigation?
   1. Possible trauma
   2. Possible sexual abuse
   3. Presence of an allergy
   4. Presence of a respiratory infection

3. The nurse prepares a teaching plan for the parent of a child diagnosed with bacterial conjunctivitis. Which, if stated by the parent, indicates a **need for further teaching**?
   1. "I need to wash my hands frequently."
   2. "I need to clean the eye as prescribed."
   3. "It is okay to share towels and washcloths."
   4. "I need to give the eye drops as prescribed."

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. The nurse is reviewing the laboratory results for a child scheduled for a tonsillectomy. The nurse determines that which laboratory value is **most** significant to review?
   1. Creatinine level
   2. Prothrombin time
   3. Sedimentation rate
   4. Blood urea nitrogen level

5. The nurse is preparing to care for a child after a tonsillectomy. The nurse documents on the plan of care to place the child in which position?
   1. Supine
   2. Side-lying
   3. High-Fowler's
   4. Trendelenburg's

6. After a tonsillectomy, the nurse reviews the surgeon's postoperative prescriptions. Which prescription would the nurse question?
   1. Monitor for bleeding.
   2. Suction every 2 hours.
   3. Give no milk or milk products.
   4. Give clear, cool liquids when awake and alert.

7. The nurse is caring for a child after a tonsillectomy. The nurse monitors the child, knowing that which finding indicates the child is bleeding?
   1. Frequent swallowing
   2. A decreased pulse rate
   3. Complaints of discomfort
   4. An elevation in blood pressure

8. Antibiotics are prescribed for a child with otitis media who underwent a myringotomy with insertion of tympanostomy tubes. The nurse provides discharge instructions to the parents regarding the administration of the antibiotics. Which statement, if made by the parents, indicates understanding of the instructions provided?
   1. "Administer the antibiotics until they are gone."
   2. "Administer the antibiotics if the child has a fever."
   3. "Administer the antibiotics until the child feels better."
   4. "Begin to taper the antibiotics after 3 days of a full course."

9. The day care nurse is observing a 2-year-old child and suspects that the child may have strabismus. Which observation made by the nurse indicates the presence of this condition?
   1. The child has difficulty hearing.
   2. The child consistently tilts the head to see.
   3. The child does not respond when spoken to.
   4. The child consistently turns the head to hear.

10. A child has been diagnosed with acute otitis media of the right ear. Which interventions would the nurse include in the plan of care? **Select all that apply.**
    - ❑ 1. Provide a soft diet.
    - ❑ 2. Position the child on the left side.
    - ❑ 3. Administer an antihistamine twice daily.
    - ❑ 4. Irrigate the right ear with normal saline every 8 hours.
    - ❑ 5. Administer ibuprofen for fever every 4 hours as prescribed and as needed.
    - ❑ 6. Instruct the parents about the need to administer the prescribed antibiotics for the full course of therapy.

ANSWERS

1. *Answer:* 1

Rationale: After tonsillectomy, if bleeding occurs, the nurse immediately turns the child to the side to prevent aspiration and then notifies the PHCP. NPO status would be maintained, and an antiemetic may be prescribed; however, the initial nursing action would be to turn the child to the side. If continuous bleeding is suspected, the surgeon is notified immediately.

Test-Taking Strategy: Note the strategic word, *initial*. Although all of the options may be appropriate to maintain physiological integrity, the initial action is to turn the child to the side to prevent aspiration.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 896.

2. *Answer:* 2

Rationale: Conjunctivitis is an inflammation of the conjunctiva. A diagnosis of chlamydial conjunctivitis in a child who is not sexually active would signal the health care provider to assess the child for possible sexual abuse. Trauma, allergy, and infection can cause conjunctivitis, but the causative organism is not likely to be *Chlamydia*.

Test-Taking Strategy: Note the age of the child and the organism that is identified in the question. Also note that options 1, 3, and 4 are comparable or alike in that they can be recognized as the common causes of conjunctivitis and they relate to a physiological problem.

Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 709, 712.

Telegram & Insta: NCLEX_RN_Edu

3. *Answer:* 3
Rationale: Conjunctivitis is an inflammation of the conjunctiva. Bacterial conjunctivitis is highly contagious, and the nurse would teach infection control measures. These include good handwashing and not sharing towels and washcloths. Options 1, 2, and 4 are correct treatment measures.
Test-Taking Strategy: Note the **strategic words,** *need for further teaching.* These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Options 1, 2, and 4 can be eliminated by recalling that bacterial conjunctivitis is highly contagious.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 189.

4. *Answer:* 2
Rationale: A tonsillectomy is the surgical removal of the tonsils. Because the tonsillar area is so vascular, postoperative bleeding is a concern. Prothrombin time, partial thromboplastin time, platelet count, hemoglobin and hematocrit, white blood cell count, and urinalysis are performed preoperatively. The prothrombin time results would identify a potential for bleeding. Creatinine level, sedimentation rate, and blood urea nitrogen would not determine the potential for bleeding.
Test-Taking Strategy: Note the **strategic word,** *most.* Focus on the surgical procedure and the **subject** of the question. The **subject** of the question relates to a laboratory value that would be important to review after tonsillectomy. Remember that bleeding is a concern. Options 1 and 4 can be eliminated because they relate to kidney function. Option 3 can be eliminated because it is unrelated to the **subject** of the question.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 895.

5. *Answer:* 2
Rationale: A tonsillectomy is the surgical removal of the tonsils. The child needs to be placed in a prone or side-lying position after the surgical procedure to facilitate drainage. Options 1, 3, and 4 would not achieve this goal.
Test-Taking Strategy: Focus on the **subject,** positioning after tonsillectomy. Focus on the surgical procedure, and visualize each of the positions described in the options. Keeping in mind that the goal is to facilitate drainage will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 895.

6. *Answer:* 2
Rationale: A tonsillectomy is the surgical removal of the tonsils. After tonsillectomy, suction equipment needs to be available, but suctioning is not performed unless there is an airway obstruction because of the risk of trauma to the surgical site. Monitoring for bleeding is an important nursing intervention after any type of surgery. Milk and milk products are avoided initially because they coat the throat, cause the child to clear the throat, and increase the risk of bleeding. Clear, cool liquids are encouraged.
Test-Taking Strategy: Focus on the **subject,** the prescription that the nurse questions. Option 1 can be eliminated first because this is a nursing action, not a medical prescription. From the remaining options, consider the anatomical location of the surgery. This would direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 896.

7. *Answer:* 1
Rationale: A tonsillectomy is the surgical removal of the tonsils. Frequent swallowing, restlessness, a fast and thready pulse, and vomiting bright red blood are signs of bleeding. An elevated blood pressure and complaints of discomfort are not indications of bleeding.
Test-Taking Strategy: Focus on the **subject,** a sign of bleeding, and use the concepts related to the signs of shock. These concepts would assist in eliminating options 2 and 4. From the remaining options, recalling that discomfort is expected and does not indicate bleeding will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 896.

8. *Answer:* 1
Rationale: A myringotomy is the insertion of tympanoplasty tubes into the middle ear to promote drainage of purulent middle ear fluid, equalize pressure, and keep the ear aerated. The nurse must instruct parents regarding the administration of antibiotics. Antibiotics need to be taken as prescribed, and the full course needs to be completed. Options 2, 3, and 4 are incorrect. Antibiotics are not tapered but are administered for the full course of therapy.
Test-Taking Strategy: Focus on the **subject,** understanding of the instructions about antibiotics. Recall that antibiotics must be taken for the full course, regardless of whether the child is feeling better. This will assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 901.

9. *Answer:* 2
Rationale: Strabismus is a condition in which the eyes are not aligned because of lack of coordination of the extraocular muscles. The nurse may suspect strabismus in a child when the child complains of frequent headaches, squints, or tilts the head to see. Other manifestations include crossed eyes, closing one eye to see, diplopia, photophobia, loss of binocular vision, or impairment of depth perception. Options 1, 3, and 4 are not indicative of this condition.
Test-Taking Strategy: Eliminate options 1 and 4 first because they are **comparable or alike** and relate to hearing. To select from the remaining options, recall that this is a condition in which the eyes are not aligned because of lack of coordination of the extraocular muscles.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 646.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

10. *Answer:* 1, 5, 6

Rationale: Acute otitis media is an inflammatory disorder caused by an infection of the middle ear. The child often has fever, pain, loss of appetite, and possible ear drainage. The child also is irritable and lethargic and may roll the head or pull on or rub the affected ear. Otoscopic examination may reveal a red, opaque, bulging, and immobile tympanic membrane. Hearing loss may be noted, particularly in chronic otitis media. The child's fever would be treated with ibuprofen. The child is positioned on the affected side to facilitate drainage. A soft diet is recommended during the acute stage to avoid pain that can occur with chewing. Antibiotics are prescribed to treat the bacterial infection and need to be administered for the full prescribed course. The ear would not be irrigated with normal saline because it can exacerbate the inflammation further. Antihistamines are not usually recommended as a part of therapy.

Test-Taking Strategy: Focus on the **subject,** care for the child with acute otitis media, and on the child's diagnosis, and note the words *acute* and *right ear.* Think about the pathophysiology associated with the disorder and the associated manifestations to select the correct options.

CHAPTER 36

Respiratory Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

Telegram & Insta: NCLEX_RN_Edu

PRIORITY CONCEPTS Gas Exchange; Health Promotion

I. Epiglottitis

A. Description

1. Bacterial form of croup
2. Inflammation of the epiglottis occurs and is most commonly caused by *Haemophilus influenzae,* although other organisms have been known to incite its occurrence. Children immunized with *H. influenzae* type b (Hib **vaccine**) are at less risk for epiglottitis.
3. Occurs most frequently in children 2 to 8 years old, but can occur from infancy to adulthood
4. Onset is abrupt, and the condition occurs most often in winter.
5. Considered an emergency situation because it can progress rapidly to complete airway obstruction

B. Assessment

1. High fever
2. Sore, red, and inflamed throat (large, cherry red, edematous epiglottis) and pain on swallowing (Fig. 36.1)
3. Absence of spontaneous cough
4. Dysphonia (muffled voice), dysphagia, dyspnea, and drooling
5. Agitation
6. **Retractions** as the child struggles to breathe
7. Inspiratory **stridor** aggravated by the supine position
8. Tachycardia
9. Tachypnea progressing to more severe respiratory distress (hypoxia, hypercapnia, respiratory acidosis, decreased level of consciousness)
10. Tripod positioning: While supporting the body with the hands, the child leans forward, thrusts the chin forward, and opens the mouth in an attempt to widen the airway.

Tripod position, drooling, stridor, and a muffled/hoarse voice are the classic signs for epiglottitis.

11. A fiberoptic nasal laryngoscopy may be necessary to assist in diagnosis (only after the airway is secured).

C. Interventions

1. Maintain a patent airway.
2. Assess respiratory status and breath sounds, noting **nasal flaring**, the use of accessory muscles, retractions, and the presence of stridor (Fig. 36.2).
3. Do not measure the temperature by the oral route.
4. Monitor pulse oximetry.
5. Prepare the child for lateral neck films to confirm the diagnosis (accompany the child to the radiology department).
6. Do not leave the child unattended.
7. Avoid placing the child in a supine position, because this position would affect the respiratory status further.
8. Maintain NPO (nothing by mouth) status.
9. Do not restrain the child or take any other measure that may agitate the child.
10. Administer intravenous (IV) fluids as prescribed; insertion of an IV line may need to be delayed until an adequate airway is established because this procedure may agitate the child.
11. Administer IV antibiotics as prescribed; these are usually followed by oral antibiotics (blood cultures before initiation of antibiotics may be necessary to identify the organism).
12. Administer analgesics and antipyretics (acetaminophen or ibuprofen) to reduce fever and throat pain as prescribed.
13. Administer corticosteroids to decrease inflammation and reduce throat edema as prescribed.
14. Heliox (mixture of helium and oxygen) may be prescribed; this medication reduces the work of breathing, reduces airway turbulence, and helps relieve airway obstruction.

Telegram & Insta: NCLEX_RN_Edu

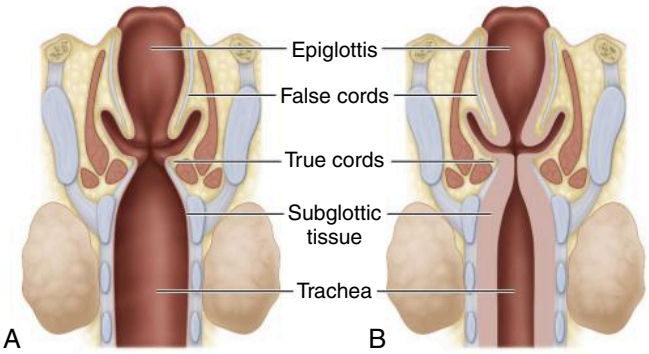

FIG. 36.1 **A,** Normal larynx. **B,** Obstruction and narrowing resulting from edema of croup.

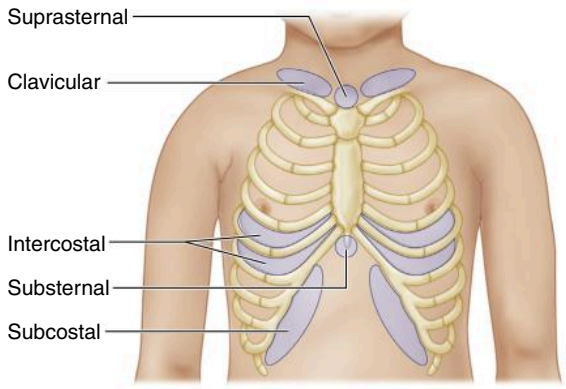

FIG. 36.2 Location of retractions.

15. Provide cool mist oxygen therapy as prescribed; high humidification cools the airway and decreases swelling.
16. Have resuscitation equipment available, and prepare for endotracheal intubation or tracheotomy for severe respiratory distress.
17. Ensure that the child is up to date with immunizations, including Hib conjugate vaccine (see Chapter 19).

⚠ If epiglottitis is suspected, no attempts would be made to visualize the posterior pharynx, obtain a throat culture, take an oral temperature, or any other interventions that may cause agitation or crying until the airway is adequately secured. Otherwise, spasm of the epiglottis can occur, leading to complete airway occlusion.

II. Laryngotracheobronchitis (Croup)

A. Description
1. Inflammation of the larynx, trachea, and bronchi
2. Most common type of croup; may be viral or bacterial and most frequently occurs in children younger than 5 years
3. Common causative organisms include parainfluenza virus types 2 and 3, respiratory syncytial virus (RSV), *Mycoplasma pneumoniae,* and influenza A and B.
4. Characterized by gradual onset that may be preceded by an upper respiratory infection

B. Assessment (Box 36.1)

C. Interventions
1. Maintain a patent airway.
2. Assess respiratory status and monitor pulse oximetry; monitor for nasal flaring, sternal retraction, and inspiratory stridor (see Fig. 36.2).
3. Monitor for adequate respiratory exchange; monitor for pallor or cyanosis.
4. Elevate the head of the bed and provide rest.
5. Provide humidified oxygen via a cool air or mist tent as prescribed for a hospitalized child (Table 36.1).
6. Instruct the parents to use a cool air vaporizer at home; other measures include having the child breathe in the cool night air or the air from an open freezer or taking the child to a cool basement or garage.
7. Provide and encourage fluid intake; IV fluids may be prescribed to maintain hydration status if the child is unable to take fluids orally.
8. Administer analgesics as prescribed to reduce fever.

BOX 36.1 Progression of Symptoms in Laryngotracheobronchitis

Stage I
- Low-grade fever
- Hoarseness
- Seal bark and brassy cough (croup cough)
- Inspiratory stridor
- Fear
- Irritability and restlessness

Stage II
- Continuous respiratory stridor
- Retractions
- Use of accessory muscles
- Crackles and wheezing
- Labored respirations

Stage III
- Continued restlessness
- Anxiety
- Pallor
- Diaphoresis
- Tachypnea
- Signs of anoxia and hypercapnia

Stage IV
- Intermittent cyanosis progressing to consistent cyanosis
- Apneic episodes progressing to cessation of breathing

Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 903, 905-906.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

TABLE 36.1 Oxygen Delivery Systems: Advantages and Disadvantages

System	Advantages	Disadvantages
Oxygen mask	Various sizes available; delivers higher O_2 concentration than cannula Able to provide a predictable concentration of oxygen if Venturi mask is used, whether child breathes through nose or mouth	Skin irritation Fear of suffocation Accumulation of moisture on face Possibility of aspiration of vomitus Difficulty in controlling O_2 concentrations (except with Venturi mask)
Nasal cannula	Provides low-moderate O_2 concentration (22%-40%) Child is able to eat and talk while getting O_2 Possibility of more complete observation of child because nose and mouth remain unobstructed	Must have patent nasal passages May cause abdominal distention and discomfort or vomiting Difficulty controlling O_2 concentrations if child breathes through mouth Inability to provide mist if desired
Oxygen tent	Provides lower O_2 concentrations (FiO_2 up to 0.3-0.5) Child is able to receive desired inspired O_2 concentrations, even while eating	Necessity for tight fit around bed to prevent leakage of oxygen Cool and wet tent environment Poor access to child; inspired O_2 levels fall when tent is entered
Oxygen hood, face tent	Provides high O_2 concentrations (FiO_2 up to 1.00) Free access to child's chest for assessment	High-humidity environment Need to remove child for feeding and care

FiO_2, Fraction of inspired oxygen; *O_2*, oxygen.
Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children*. (11th ed.). St. Louis: Elsevier. p. 943.

Telegram & Insta: NCLEX_RN_Edu

9. Teach the parents to avoid administering cough syrups or cold medicines, which may dry and thicken secretions.
10. Administer corticosteroids if prescribed to reduce inflammation and edema.
11. Administer antibiotics as prescribed, noting that they are not indicated unless a bacterial infection is present.
12. Heliox (mixture of helium and oxygen) may be prescribed.
13. Administer nebulized racemic epinephrine as prescribed.
14. Have resuscitation equipment available.
15. Provide appropriate reassurance and education to the parents or caregivers.

Isolation precautions would be implemented for a hospitalized child with an upper respiratory infection until the cause of the infection is known.

III. Bronchitis

A. Description
1. Inflammation of the trachea and bronchi; may be referred to as *tracheobronchitis*
2. Usually occurs in association with an upper respiratory infection
3. Is usually a mild disorder; causative agent is most often viral

B. Assessment
1. Fever
2. Dry, hacking, and nonproductive cough that is worse at night and becomes productive in 2 to 3 days

C. Interventions
1. Treat symptoms as necessary.
2. Monitor for respiratory distress.
3. Provide cool, humidified air to the child.
4. Encourage increased fluid intake; child may drink beverages that they like as long as the respiratory status is stable.
5. Administer antipyretics for fever as prescribed.
6. A cough suppressant may be prescribed to promote rest.

IV. Bronchiolitis and Respiratory Syncytial Virus (RSV)

A. Description
1. Bronchiolitis is an inflammation of the bronchioles that causes production of thick mucus that occludes bronchiole tubes and small bronchi.
2. RSV causes an acute viral infection and is a common cause of bronchiolitis (other organisms that cause bronchiolitis include adenoviruses, parainfluenza viruses, and human metapneumovirus).
3. RSV is highly communicable and is usually transferred via droplets or by direct contact with respiratory secretions.
4. RSV occurs primarily in the fall, winter, and spring.
5. RSV can be contracted at any age, but it typically causes the most problems with respiratory distress in children younger than 6 months of age.
6. At-risk children include those who have a chronic or disabling condition and those who are immunocompromised.

Telegram & Insta: NCLEX_RN_Edu

7. Identification of the virus is done via testing of nasal or nasopharyngeal secretions.
8. Prevention measures include the encouragement of breast-feeding/chest-feeding, the avoidance of exposure to tobacco smoke, and the use of good handwashing techniques.
9. Administering palivizumab, a monoclonal antibody, to high-risk infants. See American Academy of Pediatrics for further information about palivizumab at http://www.aappublications.org/news/2017/10/19/RSV101917

B. Assessment (Box 36.2)

C. Interventions

1. For a child with bronchiolitis, interventions are aimed at treating symptoms and include airway maintenance, cool humidified air and oxygen, adequate fluid intake, and medications.
2. For a hospitalized child with RSV, place the child in a single room to prevent transmission of the virus.
3. Ensure that nurses caring for a child with RSV do not care for other high-risk children.
4. Use contact, droplet, and standard precautions during care; using good handwashing techniques is necessary.
5. Monitor airway status and maintain a patent airway.
6. For effective airway maintenance, position the child at a 30- to 40-degree angle with the neck slightly extended to maintain an open airway and decrease pressure on the diaphragm.
7. Provide cool, humidified oxygen as prescribed.
8. Monitor pulse oximetry levels.
9. Encourage fluids; fluids administered intravenously may be necessary until the acute stage has passed.
10. Periodic suctioning may be necessary if nasal secretions are copious; may use a bulb syringe for suctioning infants at home. If a child is hospitalized and the bulb syringe is ineffective, a nasal aspirator with attached mild/moderate wall suction may be used. Suctioning would be done before feeding to promote comfort and adequate intake.
11. Antiviral medication may be prescribed.

⚠ Cough suppressants are administered with caution because they can interfere with the clearance of respiratory secretions. Honey-containing cough suppressants would not be given to children under the age of 1 due to the risk of botulism.

V. Pneumonia

A. Description

1. Inflammation of the pulmonary parenchyma or alveoli or both, caused by a virus, mycoplasmal agents, bacteria, or aspiration of foreign substances
2. The causative agent usually is introduced into the lungs through inhalation or from the bloodstream.
3. Viral pneumonia occurs more frequently than bacterial pneumonia, is seen in children of all ages, and often is associated with a viral upper respiratory infection.
4. Primary atypical pneumonia, usually caused by *Mycoplasma pneumoniae* or *Chlamydia pneumoniae,* occurs most often in the fall and winter months and is more common in crowded living conditions; it is most often seen in children 5 to 12 years old.
5. Bacterial pneumonia is often a serious infection, requiring hospitalization particularly when pleural effusion or empyema accompanies the disease.
6. Aspiration pneumonia occurs when food, secretions, liquids, or other materials enter the lung and cause inflammation and a chemical pneumonitis. Classic symptoms include an increasing cough or fever with foul-smelling sputum, deteriorating results on chest x-rays, and other signs of airway involvement.
7. Prevention of viral and bacterial pneumonia includes immunization of infants and children with heptavalent pneumococcal conjugate vaccine (see Chapter 19).

BOX 36.2 Assessment: Respiratory Syncytial Virus

Initial Manifestations

- Rhinorrhea
- Eye or ear drainage
- Pharyngitis
- Coughing
- Sneezing
- Wheezing
- Intermittent fever

Manifestations as Disease Progresses

- Increased coughing and wheezing
- Signs of air hunger
- Tachypnea and retractions
- Periods of cyanosis

Manifestations in Severe Illness

- Tachypnea of more than 70 breaths per minute
- Decreased breath sounds and poor air exchange
- Listlessness
- Apneic episodes

Adapted from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 907.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Viral pneumonia
- **1.** Assessment
  - **a.** Acute or insidious onset
  - **b.** Symptoms range from mild fever, slight cough, and malaise to high fever, severe cough, and diaphoresis.
  - **c.** Nonproductive or productive cough of small amounts of whitish sputum
  - **d.** Wheezes or fine crackles
- **2.** Interventions
  - **a.** Treatment is symptomatic.
  - **b.** Administer oxygen with cool humidified air as prescribed.
  - **c.** Increase fluid intake.
  - **d.** Administer antipyretics for fever as prescribed.
  - **e.** Administer chest physiotherapy and postural drainage as prescribed.

C. Primary atypical pneumonia
- **1.** Assessment
  - **a.** Acute or insidious onset
  - **b.** Fever (lasting several days to 2 weeks), chills, anorexia, headache, malaise, and myalgia (muscle pain)
  - **c.** Rhinitis; sore throat; and dry, hacking cough
  - **d.** Nonproductive cough initially, progressing to production of seromucoid sputum that becomes mucopurulent or blood-streaked
- **2.** Interventions
  - **a.** Treatment is symptomatic.
  - **b.** Recovery generally occurs in 7 to 10 days.

D. Bacterial pneumonia
- **1.** Assessment
  - **a.** Acute onset
  - **b.** Infant: Irritability, lethargy, poor feeding; abrupt fever (may be accompanied by seizures); respiratory distress (air hunger, tachypnea, and circumoral cyanosis)
  - **c.** Older child: Headache, chills, abdominal pain, chest pain, meningeal symptoms (meningism)
  - **d.** Hacking, nonproductive cough
  - **e.** Diminished breath sounds or scattered crackles
  - **f.** With consolidation, decreased breath sounds are more pronounced.
  - **g.** As the infection resolves, the cough becomes productive and the child expectorates purulent sputum; coarse crackles and wheezing are noted.
- **2.** Interventions
  - **a.** Blood cultures are taken and antibiotic therapy is initiated as soon as the diagnosis is suspected; in a hospitalized infant or child, IV antibiotics are usually prescribed.
  - **b.** Administer oxygen for respiratory distress as prescribed, and monitor oxygen saturation via pulse oximetry.
  - **c.** Place the child in a cool mist tent, or use humidified oxygen via nasal cannula as prescribed; cool humidification moistens the airways and assists in temperature reduction.
  - **d.** Suction mucus from the infant, using a bulb syringe or nasal aspirator (suction device), to maintain a patent airway if the infant is unable to handle secretions.
  - **e.** Administer chest physiotherapy and postural drainage every 4 hours as prescribed.
  - **f.** Promote bed rest to conserve energy.
  - **g.** Encourage the child to lie on the affected side (if pneumonia is unilateral) to splint the chest and reduce the discomfort caused by pleural rubbing.
  - **h.** Encourage fluid intake (administer cautiously to prevent aspiration); intravenously administered fluids may be necessary.
  - **i.** Administer antipyretics for fever and bronchodilators as prescribed.
  - **j.** Monitor temperature frequently because of the risk for febrile seizures.
  - **k.** Institute isolation precautions with pneumococcal or staphylococcal pneumonia (according to agency policy).
  - **l.** Administer cough suppressant if prescribed before rest times and meals if the cough is disturbing (administer with caution because cough suppressants can interfere with the clearance of respiratory secretions).
  - **m.** Continuous closed chest drainage may be necessary if purulent fluid is present (usually noted in *Staphylococcus* infections).
  - **n.** Fluid accumulation in the pleural cavity may be removed by thoracentesis; thoracentesis also provides a means for obtaining fluid for culture and for instilling antibiotics directly into the pleural cavity.

! Children with a respiratory disorder need to be monitored for weight loss and for signs of dehydration. Signs of dehydration include a sunken fontanel (infants), nonelastic skin turgor, decreased and concentrated urinary output, dry mucous membranes, and decreased tear production.

VI. Asthma

A. Description
- **1.** Asthma is a chronic inflammatory disease of the airways (see Chapter 51).

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Asthma is classified on the basis of disease severity; management includes medications, environmental control of allergens, and child and family education.
3. The allergic reaction in the airways caused by the precipitant can result in an immediate reaction with obstruction occurring, or it can result in a late bronchial obstructive reaction several hours after the initial exposure to the precipitant.
4. Mast cell release of histamine leads to a bronchoconstrictive process, bronchospasm, and obstruction.
5. Diagnosis is made on the basis of the child's symptoms, history and physical examination, chest radiograph, and laboratory tests (Box 36.3). See Table 36.2 for a classification system for asthma severity.
6. Precipitants may trigger an asthma attack (Box 36.4).

Allergy bullying in the school environment is directly associated with food allergies and happens when children who have life-threatening allergies are teased, ridiculed or even threatened or assaulted with food to which they are allergic. This needs to be assessed for as a precipitant; it is often unrecognized as a factor in clinical presentations of allergic reactions.

7. Status asthmaticus is the most severe form of an asthma attack, and is unresponsive to repeated courses of beta-agonist therapy. This is a medical emergency that can result in respiratory failure and death if not recognized and vigorously treated.

B. Assessment

1. Child has episodes of dyspnea, wheezing, breathlessness, chest tightness, and cough, particularly at night or in the early morning or both.
2. Acute asthma attacks
   - **a.** Episodes include progressively worsening shortness of breath, cough, wheezing, chest tightness, decreases in expiratory airflow secondary to bronchospasm, mucosal edema, and mucous plugging; air is trapped behind occluded or narrow airways, and hypoxemia can occur.
   - **b.** The attack begins with irritability, restlessness, headache, feeling tired, or chest tightness; just before the attack, the child may present with itching localized at the front of the neck or over the upper part of the back.
   - **c.** Respiratory symptoms include a hacking, irritable, nonproductive cough caused by bronchial edema.
   - **d.** Accumulated secretions stimulate the cough; the cough becomes rattling, and there is production of frothy, clear, gelatinous sputum.

BOX 36.3 Laboratory Tests to Assist in Diagnosing Asthma

Pulmonary Function Tests:
Spirometry testing assesses the presence and degree of disease and can determine the response to treatment.

Peak Expiratory Flow Rate Measurement:
Measures maximum flow of air that can be forcefully exhaled in 1 second; child uses a peak expiratory flowmeter to determine a "personal best" value that can be used for comparison at other times, such as during and after an asthma attack.

Bronchoprovocation Testing:
Testing that is done to identify inhaled allergens; mucous membranes are directly exposed to suspected allergen in increasing amounts.

Skin Testing:
Done to identify specific allergens.

Exercise Challenges:
Exercise is used to identify the occurrence of exercise-induced bronchospasm.

Radioallergosorbent Test:
Blood test used to identify a specific allergen.

Chest Radiograph:
May show hyperexpansion of the airways.

Note: Some tests place the child at risk for an asthma attack; testing needs to be done under close supervision.

   - **e.** The child experiences retractions.
   - **f.** Hyperresonance on percussion of the chest is noted.
   - **g.** Breath sounds become coarse and loud, with crackles, coarse rhonchi, and inspiratory and expiratory wheezing; expiration is prolonged.
   - **h.** Child may be pale or flushed, and the lips may have a deep, dark-red color that may progress to cyanosis (also observed in the nail beds and skin, especially around the mouth).
   - **i.** Restlessness, apprehension, and diaphoresis occur.
   - **j.** Child speaks in short, broken phrases.
   - **k.** Younger children assume the tripod sitting position; older children sit upright, with the shoulders in a hunched-over position, the hands on the bed or a chair, and the arms braced to facilitate the use of the accessory muscles of breathing (child avoids a lying-down position).
   - **l.** Exercise-induced attack: Cough, shortness of breath, chest pain or tightness, wheezing, and endurance problems occur during exercise.
   - **m.** Severe spasm or obstruction: Breath sounds and wheezing cannot be heard (silent chest), and cough is ineffective (represents a lack of air movement).
   - **n.** Ventilatory failure and asphyxia: Shortness of breath, with air movement in the chest restricted to the point of absent breath sounds, is noted; this is accompanied by a sudden increase in the respiratory rate.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

TABLE 36.2 Asthma Severity Classification System

Severity	Characteristics	Treatment
Mild intermittent	Intermittent symptoms less than once per week Nighttime symptoms less than twice a month Asymptomatic and normal between exacerbations FEV1 >80% predicted, PFT >20% variability	Inhaled SABA or cromolyn before exercise or allergen exposure No daily medications needed
Mild persistent	Symptoms more than 2 times/week but less than once/day May affect activity and sleep Nighttime symptoms more than twice a month FEV1 >80% predicted, PFT 20%-30% variability	One daily controlled medication, low-dose inhaled corticosteroid; cromolyn/nedocromil, leukotriene modifiers Inhaled SABA as needed
Moderate persistent	Daily symptoms, but not continual; nighttime symptoms more than once a week, but not every night Affect activity and sleep Daily use of SABA FEV1 60%-80% predicted, PFT >30%	Daily controller medications; combination inhaled medium-dose corticosteroid and LABA, especially for nighttime symptoms, cromolyn/nedocromil, leukotriene modifiers Inhaled SABA as needed
Severe persistent	Continuous daily symptoms Frequent nighttime symptoms Frequent exacerbations Physical activity limited by asthma FEV1 less than or equal to 60% predicted, PFT variability >30%	Inhaled SABA as needed Multiple daily controller meds, high-dose inhaled corticosteroid, LABA, cromolyn/nedocromil, leukotriene modifiers; may need long-term corticosteroids

FEV1, Forced expiratory volume in 1 second; *LABA,* long-acting beta-adrenergic agonists; *PFT,* pulmonary function tests; *SABA,* short-acting beta-adrenergic agonists.
Adapted from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children*. (11th ed.). St. Louis: Elsevier. p. 930.

BOX 36.4 Examples of Precipitants Triggering an Asthma Attack

Allergens
Outdoor: Trees, shrubs, weeds, grasses, molds, pollen, air pollution, sand, dust, spores
Indoor: Dust, dust mites, mold, cockroach antigen
Irritants:
Tobacco smoke, wood smoke, odors, sprays
Exposure to Occupational Irritants
Exercise
Cold Air
Changes in Weather or Temperature
Environmental Change:
Moving to a new home, starting a new school
Colds and Infections
Animals:
Cats, dogs, rodents, horses
Medications:
Aspirin, nonsteroidal antiinflammatory drugs, antibiotics, beta blockers
Strong Emotions:
Fear, anger, laughing, crying
Conditions:
Gastroesophageal reflux disease, tracheoesophageal fistula
Food Additives:
Sulfite preservatives
Foods:
Nuts, milk, other dairy products
Endocrine Factors:
Menses, pregnancy, thyroid disease

Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 930.

C. Interventions: Acute episode (see Clinical Judgment: Generate Solutions)
D. Medications

CLINICAL JUDGMENT: GENERATE SOLUTIONS

A parent comes to the emergency department with a 10-year-old child. The parent reports that over the last 3 days the child has had difficulty breathing, a cough, and wheezing. The child has a history of asthma and is using a short-acting inhaled bronchodilator at home. The child reports using the inhaler more frequently these past few days than in the past and says it has not helped much at all. The child reports feeling some respiratory congestion symptoms; otherwise, the child denies exposure to any precipitants. The nurse assesses airway patency and respiratory status. Initial respiratory assessment findings reveal an oxygen saturation of 85% and a respiratory rate of 40 breaths/min. The child is dyspneic, and wheezing is heard in the upper lobes of the lungs bilaterally. The nurse notifies the emergency department physician and plans for the following actions:

- Administering humidified oxygen by face mask
- Administering quick-relief (rescue) medications
- Initiating an intravenous (IV) line
- Administering corticosteroids
- Preparing the child for a chest radiograph
- Preparing to obtain a blood sample for determining arterial blood gas levels

1. Quick-relief medications (rescue medications): Used to treat symptoms and exacerbations (Box 36.5)
2. Long-term control medications (preventer medications): Used to achieve and maintain control of inflammation (Box 36.6)

Certain long-term control medications, such as long-acting beta-adrenergic agonists (LABAs), would not be given without an inhaled corticosteroid because of the risk for rebound bronchoconstriction.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 36.5 Quick-Relief Medications (Rescue Medications)

- Short-acting β_2 agonists (for bronchodilation)
- Anticholinergics (for relief of acute bronchospasm)
- Systemic corticosteroids (for antiinflammatory action to treat reversible airflow obstruction)

BOX 36.6 Long-Term Control (Medications to Prevent Attacks)

- Inhaled corticosteroids (for antiinflammatory action)
- Antiallergy medications (to prevent an adverse response on exposure to an allergen)
- Nonsteroidal antiinflammatory drugs (for antiinflammatory action)
- Long-acting β_2 agonists (for long-acting bronchodilation)
- Leukotriene modifiers (to prevent bronchospasm and inflammatory cell infiltration)
- Monoclonal antibody (blocks binding of immunoglobulin E [IgE] to mast cells to inhibit inflammation)

3. Nebulizer, metered-dose inhaler (MDI): May be used to administer medications; if the child has difficulty using the MDI, medication can be administered by nebulization (medication is mixed with saline and then nebulized with compressed air by a machine).
4. If an MDI is used to administer a corticosteroid, a spacer needs to be used to prevent yeast infections in the child's mouth; the spacer keeps the medication from being sprayed directly into the mouth, which can lead to irritation and possibly infection (thrush) in the mouth.
5. The child's growth patterns need to be monitored when corticosteroids are prescribed.

E. Chest physiotherapy
1. Includes breathing exercises and physical training
2. Chest physiotherapy strengthens the respiratory musculature and produces more efficient breathing patterns.
3. Chest physiotherapy is not recommended during an acute exacerbation.

F. Allergen control
1. Testing may be done to identify allergens.
2. Teach the child and parents about measures to prevent and reduce exposure to allergens (see Box 36.4).

G. Home care measures
1. Instruct the family in measures to eliminate environmental allergens.
2. Avoid extremes of environmental temperature; in cold temperatures, instruct the child to breathe through the nose, not the mouth, and to cover the nose and mouth with a scarf.
3. Avoid exposure to individuals with a respiratory infection.
4. Instruct the child and family in how to recognize early symptoms of an asthma attack.
5. Teach the child and family about medications and how to use a nebulizer, MDI, or peak expiratory flowmeter (PEF).
6. The PEF measures how fast air comes out of the lungs after exhaling forcefully after inhaling fully.
7. Instruct the child and family about the importance of home monitoring of the peak expiratory flow rate; a decrease in the expiratory flow rate may indicate impending infection or exacerbation.
8. Instruct the child in the cleaning of devices used for inhaled medications (yeast infections can occur with the use of aerosolized corticosteroids).
9. Encourage adequate rest, sleep, and a well-balanced diet.
10. Instruct the child in the importance of adequate fluid intake to liquefy secretions.
11. Assist in developing an exercise program.
12. Instruct the child in the procedure for respiratory treatments and exercises as prescribed.
13. Encourage the child to cough effectively.
14. Encourage the parents to keep immunizations up to date; annual influenza vaccinations are recommended for children 6 months of age and older.
15. Inform other health care providers and school personnel of the asthma condition.
16. Allow the child to take control of self-care measures, based on age appropriateness.

VII. Cystic Fibrosis

A. Description (Fig. 36.3)
1. A chronic multisystem disorder (autosomal recessive trait disorder) characterized by exocrine gland dysfunction
2. The mucus produced by the exocrine glands is abnormally thick, tenacious, and copious, causing obstruction of the small passageways of the affected organs, particularly in the respiratory, gastrointestinal, and reproductive systems.
3. Common symptoms are associated with pancreatic enzyme deficiency and pancreatic fibrosis caused by duct blockage, progressive chronic lung disease as a result of infection, and sweat gland dysfunction resulting in increased sodium and chloride sweat concentrations.
4. An increase in sodium and chloride in sweat and saliva forms the basis for one diagnostic test, the sweat chloride test (Box 36.7).
5. Cystic fibrosis is a progressive and incurable disorder, and respiratory failure is a common cause

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

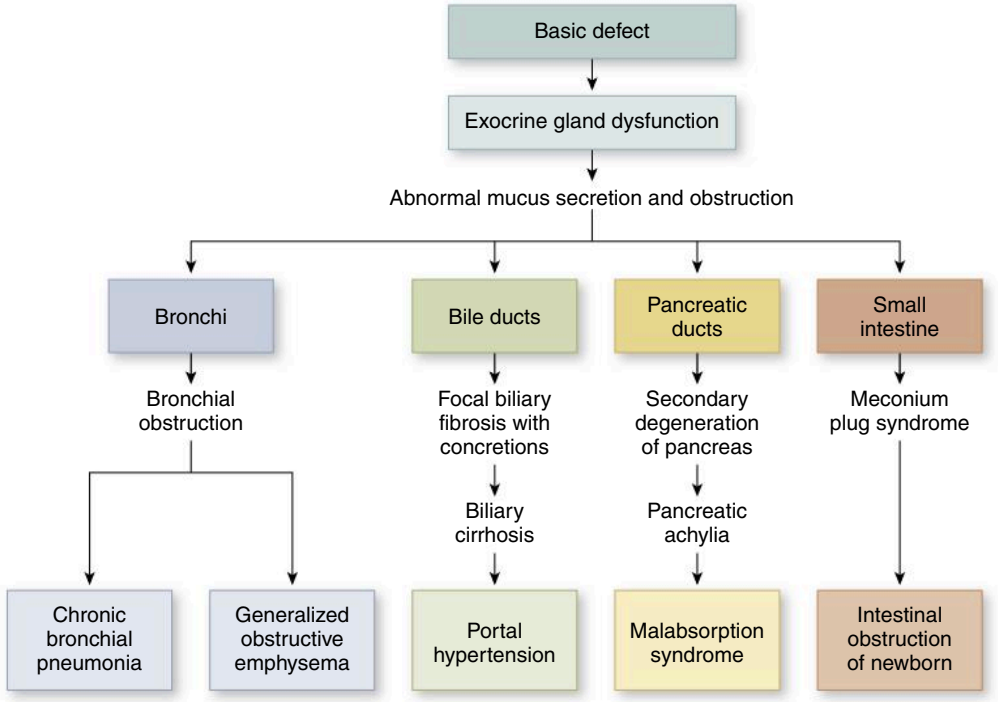

FIG. 36.3 Various effects of exocrine gland dysfunction in cystic fibrosis.

BOX 36.7 Quantitative Sweat Chloride Test

- Production of sweat is stimulated (pilocarpine iontophoresis), sweat is collected, and sweat electrolytes are measured (more than 75 mg of sweat is needed).
- Normally, the sweat chloride concentration is less than 40 mEq/L (40 mmol/L).
- Chloride concentration greater than 60 mEq/L (60 mmol/L) is a positive test result (higher than 40 mEq/L (40 mmol/L) is diagnostic in infants younger than 3 months of age.
- Chloride concentrations of 40 to 60 mEq/L (40 to 60 mmol/L) are highly suggestive of cystic fibrosis and require a repeat test.

of death; organ transplantations may be an option to increase survival rates.

6. The Cystic Fibrosis Foundation provides support to families of and individuals with cystic fibrosis. The foundation also supports the development of medications that target specific defects in the cystic fibrosis transmembrane conductance regulator (CFTR) protein. Medications that target the underlying defect in the CFTR protein are called CFTR modulators. For further information see https://www.cff.org/Research/Developing-New-Treatments/CFTR-Modulator-Types/

B. Respiratory system

1. Symptoms are produced by the stagnation of mucus in the airway, leading to bacterial colonization and destruction of lung tissue.
2. Emphysema and atelectasis occur as the airways become increasingly obstructed.
3. Chronic hypoxemia causes contraction and hypertrophy of the muscle fibers in pulmonary arteries and arterioles, leading to pulmonary hypertension and eventual cor pulmonale.
4. Pneumothorax from ruptured bullae and hemoptysis from erosion of the bronchial wall occur as the disease progresses.
5. Other respiratory symptoms
   - **a.** Wheezing and cough
   - **b.** Dyspnea
   - **c.** Cyanosis
   - **d.** Clubbing of the fingers and toes
   - **e.** Barrel chest
   - **f.** Repeated episodes of bronchitis and pneumonia

C. Gastrointestinal system

1. Meconium ileus in the newborn is the earliest manifestation.
2. Intestinal obstruction (distal intestinal obstructive syndrome) caused by thick intestinal secretions can occur; signs include pain, abdominal distention, nausea, and vomiting.
3. Stools are frothy and foul-smelling.
4. Deficiency of the fat-soluble vitamins A, D, E, and K, which can result in easy bruising, bleeding, and anemia, occurs.
5. Malnutrition and failure to thrive are a concern.
6. Demonstration of hypoalbuminemia can occur from diminished absorption of protein, resulting in generalized edema.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

7. Rectal prolapse can result from large, bulky stools and increased intra-abdominal pressure.
8. Pancreatic fibrosis can occur and places the child at risk for diabetes mellitus.

D. Integumentary system
1. Abnormally high concentrations of sodium and chloride in sweat are noted.
2. Parents report that the infant tastes "salty" when kissed.
3. Dehydration and electrolyte imbalances can occur, especially during hyperthermic conditions.

E. Reproductive system
1. Cystic fibrosis can delay **puberty** in those with vaginas.
2. Fertility can be inhibited by the highly viscous cervical secretions, which act as a plug and block sperm entry.
3. Individuals with penises are usually sterile (but not impotent), caused by the blockage of the vas deferens by abnormal secretions or by failure of normal development of duct structures.

F. Diagnostic tests
1. Quantitative sweat chloride test is positive (see Box 36.7).
2. Newborn screening may be done in some states and may consist of immunoreactive trypsinogen analysis and direct DNA analysis for mutant genes.
3. Chest x-ray reveals atelectasis and obstructive emphysema.
4. Pulmonary function tests provide evidence of abnormal small airway function.
5. Stool, fat, enzyme analysis: A 72-hour stool sample is collected to check the fat or enzyme (trypsin) content, or both (food intake is recorded during the collection).

G. Interventions: Respiratory system
1. Goals of treatment include preventing and treating pulmonary infection by improving aeration, removing secretions, and administering antibiotic medications as prescribed.
2. Monitor respiratory status, including lung sounds and the presence and characteristics of a cough.
3. Chest physiotherapy (percussion and postural drainage) on awakening and in the evening (more frequently during pulmonary infection) needs to be done every day to maintain pulmonary hygiene; chest physiotherapy would not be performed before or immediately after a meal.
4. Using a Flutter, a mucus clearance device (a small, handheld plastic pipe with a stainless-steel ball on the inside), facilitates the removal of mucus and may be prescribed. (Store away from small children, because if the device separates, the steel ball poses a choking hazard.)
5. Handheld percussors or a special vest device that provides high-frequency chest wall oscillation may be prescribed to help loosen secretions.
6. A positive expiratory pressure mask may be prescribed; use of this mask forces secretion to the upper airway for expectoration.
7. The child needs to be taught the forced expiratory technique (huffing) to mobilize secretions for expectoration.
8. Bronchodilator medication by aerosol may be prescribed; the medication opens the bronchi for easier expectoration (administered before chest physiotherapy when the child has reactive airway disease or is wheezing). Medications that decrease the viscosity of mucus may also be prescribed.
9. A physical exercise program with the aim of stimulating the expectoration of mucus and establishing an effective breathing pattern needs to be instituted.
10. Aerosolized or IV antibiotics may be prescribed; IV antibiotics may be administered at home through a central venous access device.
11. Oxygen may be prescribed during acute episodes; monitor closely for oxygen narcosis (signs include nausea and vomiting, malaise, fatigue, numbness and tingling of extremities, substernal distress), because a child with cystic fibrosis may have chronic carbon dioxide retention.
12. Lung transplantation may be an option.

H. Interventions: Gastrointestinal system
1. A child with cystic fibrosis requires a high-calorie, high-protein, and well-balanced diet to meet energy and growth needs; multivitamins and vitamins A, D, E, and K are also administered; for those with severe lung disease, energy requirements may be as high as 20% to 50% or more of the recommended daily allowance.
2. Monitor weight and for failure to thrive.
3. Monitor stool patterns and for signs of intestinal obstruction.
4. The goal of treatment for pancreatic insufficiency is to replace pancreatic enzymes; pancreatic enzymes are administered within 30 minutes of eating and administered with all meals and all snacks (enzymes would not be given if the child is NPO).
5. The amount of pancreatic enzymes administered depends on the primary health care provider's (PHCP's) preference and usually is adjusted to achieve normal growth and a decrease in the number of stools to two or three daily (additional enzymes are needed if the child is consuming high-fat foods).
6. Enteric-coated pancreatic enzymes must not be crushed or chewed; capsules can be taken apart, and the contents can be sprinkled on a small amount of food for administration.
7. Monitor for constipation, intestinal obstruction, and rectal prolapse.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. Monitor for signs of gastroesophageal reflux; place the infant in an upright position after eating, and teach the child to sit upright after eating.

I. Additional interventions
1. Monitor blood glucose levels and for signs of diabetes mellitus.
2. Ensure adequate salt intake and fluids that provide an adequate supply of electrolytes during extremely hot weather and when the child has a fever.
3. Monitor bone growth in the child.
4. Monitor for signs of retinopathy or nephropathy.
5. Provide emotional support to the parents, particularly when the child is diagnosed; parents will be fearful and uncertain about the disorder and the care involved.
6. Provide support to the child as the child transitions through the stages of growth.
7. Teach the child and parents about the care involved, and encourage independence in the child for self-care as age-appropriate.

J. Home care
1. Home care involves educating the parents and the child about all aspects of care for the disorder.
2. Inform the parents and child about the signs of complication(s), actions to take, and that follow-up care is crucial.
3. Instruct the parents to ensure that the child receives the recommended immunizations on schedule; in addition, annual influenza vaccinations are recommended for children 6 months of age and older.
4. Inform the child and parents about the Cystic Fibrosis Foundation.

An alteration in respiratory status can be a frightening experience for the child and parents. A calm and reassuring nursing approach assists in reducing fear.

VIII. Sudden Infant Death Syndrome (SIDS)

A. Description
1. *SIDS* refers to unexpected death of an apparently healthy infant younger than 1 year for whom an investigation of the death and a thorough autopsy fail to show an adequate cause of death.
2. Several theories are proposed regarding the cause of SIDS, but the exact cause is unknown.
3. SIDS most frequently occurs during winter months.
4. Death usually occurs during sleep periods, but not necessarily at night.
5. SIDS most frequently affects infants 2 to 4 months of age.
6. Incidence is higher in males.
7. Incidence is higher in Native Americans, African Americans, and Hispanics and in lower socioeconomic groups.
8. Incidence has been found to be lower in breastfed/chest-fed infants and infants sleeping with a pacifier.
9. High-risk conditions for SIDS:
   a. Prone position
   b. Use of soft bedding, sleeping in a noninfant bed such as a sofa
   c. Overheating (thermal stress)
   d. Co-sleeping
   e. Birthing parent who smoked cigarettes or abused substances during pregnancy
   f. Exposure to tobacco smoke after birth

B. Assessment
1. Infant is apneic, blue, and lifeless.
2. Frothy blood-tinged fluid is in the nose and mouth.
3. Infant may be found in any position, but typically is found in a disheveled bed, with blankets over the head, and huddled in a corner.
4. Infants may appear to have been clutching bedding.
5. Diaper may be wet and full of stool.

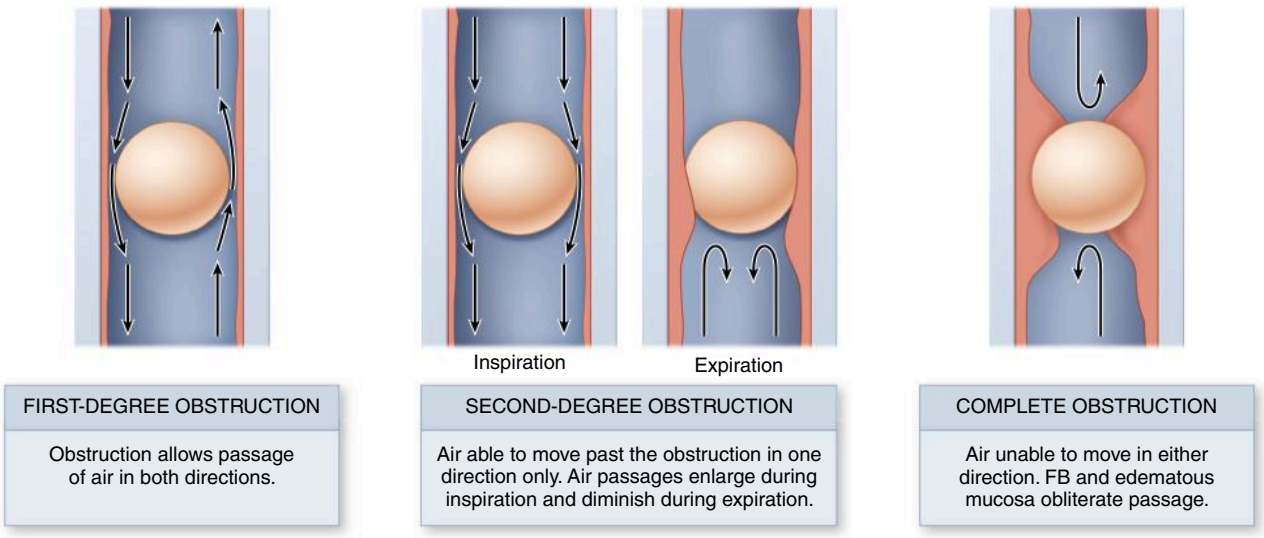
C. Prevention and interventions
1. Infants would be placed in the supine position for sleep.
2. Parents need to be taught about the risk factors: cigarette smoking and substance abuse during pregnancy.
3. Teach parents about risk factors: the use of soft bedding, putting the infant to sleep in a noninfant bed, such as on a sofa; overheating (thermal stress); co-sleeping; exposure to tobacco smoke after birth. In addition, stuffed animals or other toys need to be removed from the crib while the infant is sleeping.
4. Teach parents to monitor for positional plagiocephaly caused by the supine sleeping position; signs include flattened posterior occiput and development of a bald spot in the posterior occiput area.
5. To assist in preventing positional plagiocephaly, teach parents to alter head position during sleep, avoid excessive time in infant seats and bouncers, and place the infant in a prone position while awake (monitor the infant when in the prone position).
6. If SIDS occurs, the parents need a great deal of support as they grieve and mourn, especially because the event was sudden, unexpected, and unexplained.

IX. Foreign Body Aspiration

A. Description (Fig. 36.4)
1. Swallowing and aspiration of a foreign body into the air passages

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu



Inspiration
Expiration
FIRST-DEGREE OBSTRUCTION
Obstruction allows passage of air in both directions.
SECOND-DEGREE OBSTRUCTION
Air able to move past the obstruction in one direction only. Air passages enlarge during inspiration and diminish during expiration.
COMPLETE OBSTRUCTION
Air unable to move in either direction. FB and edematous mucosa obliterate passage.

FIG. 36.4 Mechanisms of airway obstruction by a foreign body (FB).

2. Most inhaled foreign bodies lodge in the main stem or lobar bronchus.
3. The most common offending foods are round in shape and include items such as hot dogs, candy, peanuts, popcorn, or grapes.

B. Assessment
1. Initially, choking, gagging, coughing, and retractions are general findings.
2. If the condition worsens, cyanosis may occur.
3. Laryngotracheal obstruction leads to dyspnea, stridor, cough, and hoarseness.
4. Bronchial obstruction produces paroxysmal cough, wheezing, asymmetrical breath sounds, and dyspnea.
5. If any obstruction progresses, unconsciousness and asphyxiation may occur.
6. Partial obstructions may occur without symptoms.
7. Distressed child cannot speak, becomes cyanotic, and collapses.

C. Interventions: Abdominal thrust maneuver is used for the removal of a foreign body (or relief of choking) in a child; refer to the American Heart Association at American Heart Association (2020). Highlights of the 2020 American Heart Association Guidelines for CPR and ECC. p. 11 @ https://www.ahajournals.org/doi/10.1161/CIR.0000000000000901?utm_campaign=sciencenews20-21&utm_source=science-news&utm_medium=phd-link&utm_content=phd10-21-20
1. Institute emergency care measures.
2. After instituting emergency care measures, removal by endoscopy may be necessary.
   a. After endoscopy, the child receives high-humidity air.
   b. Observe for signs and symptoms of airway edema.
3. Prevention
   a. Keep small objects, including rubber balloons, out of reach of small children.
   b. Avoid giving small children small, round food items.
4. Parent, day care provider, and babysitter education
   a. Teach about the hazards of aspiration.
   b. Discuss potential situations in which small items may be aspirated.
   c. Teach about the symptoms of aspiration.
   d. Teach how to perform emergency care measures.

X. Tuberculosis

A. Description
1. Tuberculosis is a contagious disease caused by *Mycobacterium tuberculosis*, an acid-fast bacillus (see Chapter 51).
2. Multidrug-resistant strains of *M. tuberculosis* occur because of child or family noncompliance with therapeutic regimens.
3. The route of transmission of *M. tuberculosis* is through inhalation of droplets from an individual with active tuberculosis.
4. There is an increased incidence in urban low-income areas, nonwhite racial or ethnic groups, and first-generation immigrants from endemic countries.
5. Most children are infected by a family member or by another individual with whom they have frequent contact, such as a babysitter.

B. Assessment
1. Child may be asymptomatic or develop symptoms such as malaise, fever, cough, weight loss, anorexia, or lymphadenopathy.
2. Specific symptoms related to the site of infection, such as the lungs, brain, or bone, may be present.
3. With increased time, asymmetrical expansion of the lungs, decreased breath sounds, crackles, and dullness to percussion develop.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 36.8 Tuberculin Skin Test or Mantoux Test Interpretation

- Induration measuring 15 mm or more is considered to be a positive reaction in children 4 years or older who do not have any risk factors.
- Induration measuring 10 mm or more is considered to be a positive reaction in children younger than 4 years and in children with chronic illness or at high risk for exposure to tuberculosis.
- Induration measuring 5 mm or more is considered to be positive for the highest-risk groups, such as children with immunosuppressive conditions or human immunodeficiency virus (HIV) infection.

C. Tuberculin skin test (TST) or Mantoux test (Box 36.8)
1. The test produces a positive reaction 2 to 12 weeks after the initial infection.
2. The test determines whether a child has been infected and has developed a sensitivity to the protein of the tubercle **bacillus**; a positive reaction does not confirm the presence of active disease (exposure versus presence).
3. After a child reacts positively, the child will always react positively; a positive reaction in a previously negative child indicates that the child has been infected since the last test.
4. Tuberculosis testing would not be done at the same time as measles immunization (viral interference from the measles vaccine may cause a false-negative result).

D. Sputum culture
1. A definitive diagnosis is made by showing the presence of mycobacteria in a culture.
2. Chest x-rays are supplemental to sputum cultures and are not definitive alone.
3. Because an infant or young child often swallows sputum rather than expectorates it, gastric washings (aspiration of lavaged contents from the fasting stomach) may be done to obtain a specimen; the specimen is obtained in the early morning before breakfast.

E. Interventions
1. Medications
   - **a.** A 9-month course of isoniazid may be prescribed to prevent a latent infection from progressing to clinically active tuberculosis and to prevent initial infection in children in high-risk situations; a 12-month course may be prescribed for a child infected with human immunodeficiency virus (HIV).
   - **b.** Recommendation for a child with clinically active tuberculosis may include combination administration of isoniazid, rifampin, and pyrazinamide daily for 2 months, and then isoniazid and rifampin twice weekly for 4 months.
   - **c.** Inform the parents and child that bodily fluids, including urine, may turn an orange-red color with some tuberculosis medications.
   - **d.** Directly observed therapy may be necessary for some children.
2. Place children with active disease who are contagious on respiratory isolation until medications have been initiated, sputum cultures show a diminished number of organisms, and cough is improving; this includes use of a personally fitted air-purifying N95 or N100 respirator (mask) by the nurse caring for the child.
3. Stress the importance of adequate rest and adequate diet.
4. Instruct the child and family about measures to prevent the transmission of tuberculosis.
5. Case finding and follow-up with known contacts is crucial to decrease the number of cases of individuals with active tuberculosis.

PRACTICE QUESTIONS

1. A 10-year-old child with asthma is treated for acute exacerbation in the emergency department. The nurse caring for the child would monitor for which sign, knowing that it indicates a worsening of the condition?
   1. Warm, dry skin
   2. Decreased wheezing
   3. Pulse rate of 90 beats per minute
   4. Respirations of 18 breaths per minute

2. The parent of an 8-year-old child being treated for right lower lobe pneumonia at home calls the clinic nurse. The parent tells the nurse that the child complains of discomfort on the right side and that ibuprofen is ineffective. Which instruction would the nurse provide to the parent?
   1. Increase the dose of ibuprofen.
   2. Increase the frequency of ibuprofen.
   3. Encourage the child to lie on the left side.
   4. Encourage the child to lie on the right side.

3. A new parent expresses concern to the nurse regarding sudden infant death syndrome (SIDS). The parent asks the nurse how to position the new infant for sleep. In which position would the nurse tell the parent to place the infant?
   1. Side or prone
   2. Back or prone
   3. Stomach with the face turned
   4. Back rather than on the stomach

4. The clinic nurse is providing instructions to the parent of a child with cystic fibrosis regarding the immunization schedule for the child. Which statement would the nurse make to the parent?
   1. "The immunization schedule will need to be altered."
   2. "The child should not receive any hepatitis vaccines."
   3. "The child will receive all of the immunizations except for the polio series."

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. "The child will receive the recommended basic series of immunizations along with a yearly influenza vaccination."

5. The emergency department nurse is caring for a child diagnosed with epiglottitis. In assessing the child, the nurse would monitor for which indication that the child may be experiencing airway obstruction?
   1. The child exhibits nasal flaring and bradycardia.
   2. The child is leaning forward, with the chin thrust out.
   3. The child has a low-grade fever and complains of a sore throat.
   4. The child is leaning backward, supporting self with the hands and arms.

6. A child with laryngotracheobronchitis (croup) is placed in a cool mist tent. The parent becomes concerned because the child is frightened, consistently crying, and trying to climb out of the tent. Which is the **most appropriate** nursing action?
   1. Tell the parent that the child must stay in the tent.
   2. Place a toy in the tent to make the child feel more comfortable.
   3. Call the pediatrician and obtain a prescription for a mild sedative.
   4. Let the parent hold the child and direct the cool mist over the child's face.

7. The clinic nurse reads the results of a tuberculin skin test (TST) on a 3-year-old child. The results indicate an area of induration measuring 10 mm. The nurse would interpret these results as which finding?
   1. Positive
   2. Negative
   3. Inconclusive
   4. Definitive and requiring a repeat test

8. The parent of a hospitalized 2-year-old child with viral laryngotracheobronchitis (croup) asks the nurse why the pediatrician did not prescribe antibiotics. Which response would the nurse make?
   1. "The child may be allergic to antibiotics."
   2. "The child is too young to receive antibiotics."
   3. "Antibiotics are not indicated unless a bacterial infection is present."
   4. "The child still has the maternal antibodies from birth and does not need antibiotics."

9. The nurse is caring for an infant with bronchiolitis, and diagnostic tests have confirmed respiratory syncytial virus (RSV). On the basis of this finding, which is the **most appropriate** nursing action?
   1. Initiate strict enteric precautions.
   2. Move the infant to a private room.
   3. Leave the infant in the present room, because RSV is not contagious.
   4. Inform the staff that using standard precautions is all that is necessary when caring for the child.

10. The nurse is preparing for the admission of an infant with a diagnosis of bronchiolitis caused by respiratory syncytial virus (RSV). Which interventions would the nurse include in the plan of care? **Select all that apply.**
    - ❑ 1. Place the infant in a private room.
    - ❑ 2. Ensure that the infant's head is in a flexed position.
    - ❑ 3. Wear a mask, gown, and gloves when in contact with the infant.
    - ❑ 4. Place the infant in a tent that delivers warm humidified air.
    - ❑ 5. Position the infant on the side, with the head lower than the chest.
    - ❑ 6. Ensure that nurses caring for the infant with RSV do not care for other high-risk children.

ANSWERS

1. *Answer:* 2

Rationale: Asthma is a chronic inflammatory disease of the airways. Decreased wheezing in a child with asthma may be interpreted incorrectly as a positive sign when it may actually signal an inability to move air. A "silent chest" is an ominous sign during an asthma episode. With treatment, increased wheezing actually may signal that the child's condition is improving. Warm, dry skin indicates an improvement in the child's condition, because the child is normally diaphoretic during exacerbation. The normal pulse rate in a 10-year-old is 70 to 110 beats per minute. The normal respiratory rate in a 10-year-old is 16 to 20 breaths per minute.

Test-Taking Strategy: Note the word *worsening* in the question. Options 3 and 4 can be eliminated because they are comparable or alike in that they are normal vital signs. From the remaining options, recall that a "silent chest" is an ominous sign during an asthma episode and indicates severe bronchial spasm or obstruction.

Reference: Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology.* (7th ed.). St. Louis: Elsevier. pp. 706-707.

2. *Answer:* 4

Rationale: Pneumonia is an inflammation of the pulmonary parenchyma or alveoli, or both, caused by a virus, mycoplasmal agents, bacteria, or aspiration of foreign substances.

Telegram & Insta: NCLEX_RN_Edu

Splinting of the affected side by lying on that side may decrease discomfort. It would be inappropriate to advise the parent to increase the dose or frequency of the ibuprofen. Lying on the left side would not be helpful in alleviating discomfort.
Test-Taking Strategy: Options 1 and 2 can be eliminated because they are **comparable or alike.** Recall that the nurse does not adjust the dose or frequency of medications. Recalling the principles related to splinting an incision in the postoperative client will assist in directing you to the correct option, because these principles can be applied in this situation.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 912.

3. *Answer:* 4
Rationale: SIDS is the unexpected death of an apparently healthy infant younger than 1 year for whom an investigation of the death and a thorough autopsy fail to show an adequate cause of death. Several theories are proposed regarding the cause, but the exact cause is unknown. Nurses need to encourage parents to place the infant on the back (supine) for sleep. Infants in the prone position (on the stomach) may be unable to move their heads to the side, increasing the risk of suffocation. The infant may have the ability to turn to a prone position from the side-lying position.
Test-Taking Strategy: Eliminate options 1, 2, and 3 because they are **comparable or alike.** Remember that the infant needs to be placed on the back.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p.384.

4. *Answer:* 4
Rationale: Cystic fibrosis is a chronic multisystem disorder (autosomal recessive trait disorder) characterized by exocrine gland dysfunction. The mucus produced by the exocrine glands is abnormally thick, tenacious, and copious, causing obstruction of the small passageways of the affected organs, particularly in the respiratory, gastrointestinal, and reproductive systems. Adequately protecting children with cystic fibrosis from communicable diseases by immunization is essential. In addition to the basic series of immunizations, a yearly influenza immunization is recommended for children with cystic fibrosis. Options 1, 2, and 3 are incorrect.
Test-Taking Strategy: Eliminate options 1, 2, and 3 because they are **comparable or alike,** indicating that the immunization schedule will be adjusted in some way. Recalling the importance of protection from communicable diseases, particularly in children with a disorder such as cystic fibrosis, will assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 177-178.

5. *Answer:* 2
Rationale: Epiglottitis is a bacterial form of croup. A primary concern is that it can progress to acute respiratory distress. Clinical manifestations suggestive of airway obstruction include tripod positioning (leaning forward while supported by arms, chin thrust out, mouth open), nasal flaring, the use of accessory muscles for breathing, and the presence of stridor. Option 4 is an incorrect position. Options 1 and 3 are incorrect because epiglottitis causes tachycardia and a high fever.
Test-Taking Strategy: Focus on the **subject,** manifestations of airway obstruction in a child with epiglottitis. Eliminate option 1 first, because tachycardia rather than bradycardia would occur in a child experiencing respiratory distress. Eliminate option 3 next, knowing that a high fever occurs with epiglottitis. From the remaining options, visualize the descriptions in each, and determine which position would best assist a child experiencing respiratory distress.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's Nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 903.

6. *Answer:* 4
Rationale: Laryngotracheobronchitis (croup) is the inflammation of the larynx, trachea, and bronchi and is the most common type of croup. Cool mist therapy may be prescribed to liquefy secretions and to assist in breathing. If the use of a tent or hood is causing distress, treatment may be more effective if the child is held by the parent and a cool mist is directed toward the child's face (blow-by). A mild sedative would not be administered to the child. Crying would increase hypoxia and aggravate laryngospasm, which may cause airway obstruction. Options 1 and 2 would not alleviate the child's fear.
Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Focus on the **subject,** the child's fear. Options 1, 2, and 3 are **comparable or alike** in that they do not address the fear. The correct option is the one that addresses the **subject** of the question.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 905.

***7. Answer:* 1**
Rationale: Induration measuring 10 mm or more is considered to be a positive result in children younger than 4 years of age and in children with chronic illness or at high risk for exposure to tuberculosis. A reaction of 5 mm or more is considered to be a positive result for the highest risk groups, such as a child with an immunosuppressive condition or a child with human immunodeficiency virus (HIV) infection. A reaction of 15 mm or more is positive in children 4 years or older without any risk factors.
Test-Taking Strategy: Options 3 and 4 are **comparable or alike** and can be eliminated first. From the remaining options, focus on the **data in the question** and note the child's age to assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 914-915.

8. *Answer:* 3
Rationale: Laryngotracheobronchitis (croup) is the inflammation of the larynx, trachea, and bronchi and is the most common type of croup. It can be viral or bacterial. Antibiotics are not indicated in the treatment of croup unless a bacterial infection is present. Options 1, 2, and 4 are incorrect. In

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

addition, no supporting data in the question indicate that the child may be allergic to antibiotics.
Test-Taking Strategy: Focus on the **subject,** indications for the use of antibiotics. Eliminate option 1 because there are no supporting data in the question regarding the potential for allergies. Noting the word *viral* in the question and noting the age of the child will assist in eliminating options 2 and 4.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 904-906.

9. *Answer:* 2
Rationale: RSV is a highly communicable disorder and is transmitted via droplets and direct contact with respiratory secretions. The use of contact, droplet, and standard precautions during care is necessary. Good handwashing technique and protection with gloves, gown, and a mask are needed to prevent transmission. An infant with RSV would be placed in a private room to prevent transmission. Enteric precautions are unnecessary.
Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Focus on the **subject,** the method of transmission of RSV. Remember that the virus is transmitted via droplets and direct contact with respiratory secretions. An infant with RSV is contagious and needs to be placed in a private room.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 908.

10. *Answer:* 1, 3, 6
Rationale: RSV is a highly communicable disorder and is transmitted via droplets or contact with respiratory secretions. The use of contact, droplet, and standard precautions during care (wearing gloves, mask, and a gown) reduces nosocomial transmission of RSV. In addition, it is important to ensure that nurses caring for a child with RSV do not care for other high-risk children to prevent the transmission of the infection. An infant with RSV needs to be placed in a private room. The infant would be positioned with the head and chest at a 30- to 40-degree angle and the neck slightly extended to maintain an open airway and decrease pressure on the diaphragm. Cool humidified oxygen is delivered to relieve dyspnea, hypoxemia, and insensible water loss from tachypnea.
Test-Taking Strategy: Focus on the **subject,** care of the child with bronchiolitis and RSV. Recalling the mode of transmission of RSV will assist in answering correctly. Remember that RSV is highly communicable and is transmitted via droplets or direct contact with respiratory secretions.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 908.

CHAPTER 37

Cardiovascular Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

CONCEPTS Gas Exchange; Perfusion

I. Hyperlipidemia

A. Description

1. A condition in which there are high levels of lipids circulating in the blood, which can predispose a child to heart disease

2. Laboratory values for lipids for individuals aged 2 to 19 years are as follows:

a. Total cholesterol: less than 170 mg/dL (4.25 mmol/L) is acceptable, 170 to 199 mg/dL (4.25 to 4.9 mmol/L) is borderline, 200 mg/dL (5 mmol/L) or greater is high.

b. Low-density lipoprotein cholesterol: less than 110 mg/dL (2.75 mmol/L) is acceptable, 110 to 129 mg/dL (2.75 to 3.22 mmol/L) is borderline, 130 mg/dL (3.25 mmol/L) or greater is high.

c. High-density lipoprotein cholesterol: greater than 45 mg/dL (1.12 mmol/L) is acceptable, 40 to 45 mg/dL (1.0 to 1.12 mmol/L) is borderline, less than 40 mg/dL (1.0 mmol/L) is low.

d. Triglycerides: less than 100 mg/dL (1.14 mmol/L) for 9 years and younger is acceptable; less than 130 mg/dL (1.48 mmol/L) for 10 years and older is acceptable.

e. Any person with hyperlipidemia as a child is likely to have the condition later in life, and it predisposes them to cardiac events.

f. Referral to a specialist (in cardiology) should be made if there is an elevation in any of the above values.

g. Treatment focuses on lifestyle modifications and behavioral changes. See Box 33.1 for recommended dietary and physical activity changes for preventing diabetes mellitus, which also applies to the treatment focus for hyperlipidemia.

II. Heart Failure (HF)

A. Description

1. HF (Box 37.1) is the inability of the heart to pump a sufficient amount of blood to meet the metabolic and oxygen needs of the body.

2. In infants and children, inadequate cardiac output most commonly is caused by congenital heart defects (shunt, obstruction, or a combination of both) that produce an excessive volume or pressure load on the myocardium.

3. In infants and children, a combination of left-sided and right-sided HF is usually present.

4. The goals of treatment are to improve cardiac function, remove accumulated fluid and sodium, decrease cardiac demands, improve tissue oxygenation, and decrease oxygen consumption; depending on the cause, surgery may be required.

B. Assessment of early signs

1. Tachycardia, especially during rest and slight exertion

2. Tachypnea

3. Profuse scalp diaphoresis, especially in infants

4. Fatigue and irritability

5. Sudden weight gain

6. Respiratory distress

C. Interventions

1. Monitor for early signs of HF.

2. Monitor for respiratory distress (count respirations for 1 minute).

3. Monitor apical pulse (count apical pulse for 1 minute), and monitor for dysrhythmias.

4. Monitor temperature for hyperthermia and for other signs of infection, particularly respiratory infection.

5. Monitor strict intake and output; weigh diapers as appropriate for most accurate output.

6. Monitor daily weight to assess for fluid retention; a weight gain of 0.5 kg (1 lb) in 1 day is caused by the accumulation of fluid; weigh the child using the same scale and at the same time each day.

7. Monitor for facial or peripheral dependent edema, auscultate lung sounds, and report abnormal findings indicating excessive fluid in the body.

Telegram & Insta: NCLEX_RN_Edu

BOX 37.1 Assessment Findings in Left- and Right-Sided Heart Failure

Left-Sided Failure

- Crackles and wheezes
- Cough
- Dyspnea
- Grunting (infants)
- Head bobbing (infants)
- Nasal flaring
- Orthopnea
- Periods of cyanosis
- Retractions
- Tachypnea

Right-Sided Failure

- Ascites
- Hepatosplenomegaly
- Jugular vein distention
- Oliguria
- Peripheral edema, especially dependent edema, and periorbital edema
- Weight gain

8. Elevate the head of the bed in a semi-Fowler's position.
9. Maintain a neutral thermal environment to prevent cold stress in infants.
10. Provide rest and decrease environmental stimuli.
11. Administer cool humidified oxygen as prescribed, using an oxygen hood for young infants and a nasal cannula or face mask for older infants and children.
12. Organize nursing activities to allow for uninterrupted sleep.
13. Maintain adequate nutritional status.
14. Feed when hungry and soon after awakening, conserving energy and oxygen supply.
15. Provide small, frequent feedings, conserving energy and oxygen supply.
16. Administer medications as prescribed, which may include digoxin, diuretics, and afterload reducers such as angiotensin-converting enzyme (ACE) inhibitors.
17. Administer digoxin as prescribed.
    a. Assess apical heart rate for 1 minute before administration.
    b. Withhold digoxin if the apical pulse is less than 90 to 110 beats per minute in infants and young children and less than 70 beats per minute in older children, as prescribed.
    c. Check the prescribed dose carefully to ensure it is a safe, age-appropriate dose; follow agency policy and question any unclear prescription.
18. Monitor digoxin levels and for signs of digoxin toxicity, including anorexia, poor feeding, nausea, vomiting, bradycardia, and dysrhythmias.
19. The optimal therapeutic digoxin level range is 0.8 to 2 ng/mL (1.02 to 2.55 nmol/L; toxicity is usually seen at >2 ng/mL (2.55 nmol/L) level.
20. Administer angiotensin-converting enzyme inhibitors as prescribed.
    a. Monitor for hypotension, renal dysfunction, and cough when ACE inhibitors are administered.
    b. Assess blood pressure; serum protein, albumin, blood urea nitrogen, and creatinine levels; white blood cell count; urine output; urinary specific gravity; and urinary protein level.
21. Administer diuretics such as furosemide as prescribed.
    a. Monitor for signs and symptoms of hypokalemia (serum potassium level <3.5 mEq/L [3.5 mmol/L]), including muscle weakness and cramping, confusion, irritability, restlessness, and inverted T waves or prominent U waves on the electrocardiogram.
    b. If signs and symptoms of hypokalemia are present and the child is also being administered digoxin, monitor closely for digoxin toxicity, because hypokalemia potentiates digoxin toxicity.
22. Administer potassium supplements and provide dietary sources of potassium as prescribed.
    a. Supplemental potassium would be given only if indicated by serum potassium levels and if adequate renal function is evident and is usually necessary when administering a potassium-losing diuretic such as furosemide.
    b. Encourage foods that the child will eat that are high in potassium, as appropriate, such as bananas, baked potato skins, and peanut butter.
23. Monitor serum electrolyte levels, particularly the potassium level (normal level is 3.5 to 5.0 mEq/L [3.5 to 5.0 mmol/L]).
24. Limit fluid intake as prescribed in the acute stage.
25. Monitor for signs and symptoms of dehydration, including sunken fontanel (infant), nonelastic skin turgor, dry mucous membranes, decreased tear production, decreased urine output, and concentrated urine.
26. Monitor sodium levels as prescribed.
    a. Normal level is 135 to 145 mEq/L (135 to 145 mmol/L).
    b. Many infant formulas have slightly more sodium than breast/chest milk.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

27. Instruct the parents regarding administration of digoxin (Box 37.2).
28. Instruct the parents in cardiopulmonary resuscitation (CPR).
    a. For the general public, the American Heart Association (AHA) recommends compression-only CPR for a witnessed sudden collapse of an adult or teenager.
    b. If the responder has CPR training, the responder needs to perform CPR with a 30:2 compression-to-ventilation ratio.
    c. For the infant and child, if there are two rescuers, then the compression-to-ventilation ratio is 15:2 or for one rescuer 30:2.
    d. For American Heart Association current CPR guidelines, refer to American Heart Association (2020). Part 4: Pediatric Basic and Advanced Life Support: 2020 American Heart Association Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care, *Circulation*. https://www.ahajournals.org/doi/10.1161/CIR.0000000000000901 and American Heart Association (2020). *Highlights of the 2020 American Heart Association Guidelines for CPR and ECC*. p. 11 @ https://cpr.heart.org/en/resuscitation-science/cpr-and-ecc-guidelines

BOX 37.2 Home Care Instructions for Administering Digoxin

- Administer as prescribed.
- Use an accurate measuring device as provided by the pharmacist.
- Administer 1 hour before or 2 hours after feedings.
- Use a calendar to mark off the dose administered.
- Do not mix medication with foods or fluid.
- If a dose is missed and more than 4 hours has elapsed, withhold the dose and give the next dose at the scheduled time; if less than 4 hours has elapsed, administer the missed dose.
- If the child vomits, do not administer a second dose. (Follow the pediatrician's prescription.)
- If more than 2 consecutive doses have been missed, notify the pediatrician; do not increase or double the dose for missed doses.
- If the child has teeth, give water after the medication; if possible, brush the teeth to prevent tooth decay from the sweetened liquid.
- Monitor for signs of toxicity, such as poor feeding or vomiting.
- If the child becomes ill, notify the pediatrician.
- Keep the medication in a locked cabinet.
- Call the Poison Control Center immediately if accidental overdose occurs.

The parents need to be provided with a medication guide for any medication prescribed for the infant or child. In addition, the nurse needs to review the instructions in the guide and provide an opportunity for the parents to demonstrate medication administration procedures.

BOX 37.3 Manifestations of Decreased Cardiac Output

- Activity intolerance
- Decreased peripheral pulses
- Feeding difficulties
- Hypotension
- Irritability, restlessness, lethargy
- Oliguria
- Pale, cool extremities
- Tachycardia

III. Defects with Increased Pulmonary Blood Flow

A. Description
1. Intracardiac communication along the septum or an abnormal connection between the great arteries allows blood to flow from the high-pressure left side of the heart to the low-pressure right side of the heart.
2. The infant typically shows signs and symptoms of HF.

B. Atrial septal defect (ASD)
1. ASD is an abnormal opening between the right and left atria that causes an increased flow of oxygenated blood into the right side of the heart.
2. Right atrial and ventricular enlargement occurs.
3. Infant may be asymptomatic or may develop HF.
4. Manifestations of decreased cardiac output may be present (Box 37.3).
5. Types
    a. ASD 1 (ostium primum): Opening is at the lower end of the septum.
    b. ASD 2 (ostium secundum): Opening is near the center of the septum.
    c. ASD 3 (sinus venosus defect): Opening is near the junction of the superior vena cava and the right atrium.
6. Management
    a. Defect may be closed during a cardiac catheterization.
    b. Open repair with cardiopulmonary bypass may be performed and usually is performed before school age.

C. Atrioventricular canal defect
1. The defect results from incomplete fusion of the endocardial cushions.
2. The defect is the most common cardiac defect in Down's syndrome.
3. A characteristic murmur is present.
4. The infant usually has mild to moderate HF, with cyanosis increasing with crying.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

5. Signs and symptoms of decreased cardiac output may be present.
6. Management can include pulmonary artery banding for infants with severe symptoms (palliative) or complete repair via cardiopulmonary bypass.

D. Patent ductus arteriosus

1. Patent ductus arteriosus is failure of the fetal ductus arteriosus (shunt connecting the aorta and the pulmonary artery) to close within the first weeks of life.
2. A characteristic machinery-like murmur is present.
3. An infant may be asymptomatic or may show signs of HF.
4. A widened pulse pressure and bounding pulses are present.
5. Signs and symptoms of decreased cardiac output may be present.
6. Management
   a. Indomethacin, a prostaglandin inhibitor, may be administered to close a patent ductus in premature infants and some newborns.
   b. The defect may be closed during cardiac catheterization, or the defect may require surgical management.
   c. Prostaglandin E may be used to keep the PDA open in ductal-dependent cardiac defect.

E. Ventricular septal defect (VSD)

1. VSD is an abnormal opening between the right and left ventricles.
2. Many VSDs close spontaneously during the first year of life in children with small or moderate defects.
3. A characteristic murmur is present.
4. Signs and symptoms of HF are commonly present.
5. Signs and symptoms of decreased cardiac output may be present.
6. Management
   a. Closure during cardiac catheterization may be possible.
   b. Open repair may be done with cardiopulmonary bypass.

IV. Obstructive Defects

A. Description

1. Blood exiting a portion of the heart meets an area of anatomical narrowing (**stenosis**), causing obstruction to blood flow.
2. The location of narrowing is usually near the valve of the obstructive defect.
3. Infants and children exhibit signs of HF.
4. Children with mild obstruction may be asymptomatic.

B. Aortic stenosis

1. Aortic stenosis is a narrowing or stricture of the aortic valve, causing resistance to blood flow from the left ventricle into the aorta, resulting in decreased cardiac output, left ventricular hypertrophy, and pulmonary vascular congestion.
2. Valvular stenosis is the most common type and usually is caused by malformed cusps, resulting in a bicuspid rather than a tricuspid valve, or fusion of the cusps.
3. A characteristic murmur is present.
4. Infants with severe defects show signs of decreased cardiac output.
5. Children show signs of activity intolerance, chest pain, and dizziness when standing for long periods.
6. Management
   a. Dilation of the narrowed valve may be done during cardiac catheterization.
   b. Surgical aortic valvotomy (palliative) may be done; a valve replacement may be required at a second procedure.

C. Coarctation of the aorta

1. Coarctation of the aorta is localized narrowing near the insertion of the ductus arteriosus.
2. Blood pressure is higher in the upper extremities than in the lower extremities; bounding pulses in the arms, weak or absent femoral pulses, and cool lower extremities may be present.
3. Signs of HF may occur in infants.
4. Signs and symptoms of decreased cardiac output may be present.
5. Children may experience headaches, dizziness, fainting, and epistaxis resulting from hypertension.
6. Management of the defect may be done via balloon angioplasty in children; restenosis can occur.
7. Surgical management
   a. Mechanical ventilation and medications to improve cardiac output are often necessary before surgery.
   b. Resection of the coarcted portion with end-to-end anastomosis of the aorta or enlargement of the constricted section, using a graft, may be required.
   c. Because the defect is outside the heart, cardiopulmonary bypass is not required, and a thoracotomy incision is used.

! With coarctation of the aorta, the blood pressure is higher in the upper extremities than in the lower extremities. In addition, bounding pulses in the arms, weak or absent femoral pulses, and cool lower extremities may be present.

D. Pulmonary stenosis

1. Pulmonary stenosis is narrowing at the entrance to the pulmonary artery.
2. Resistance to blood flow causes right ventricular hypertrophy and decreased pulmonary blood flow; the right ventricle may be hypoplastic.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Pulmonary atresia is the extreme form of pulmonary stenosis in that there is total fusion of the commissures and no blood flow to the lungs.
4. A characteristic murmur is present.
5. Infants or children may be asymptomatic.
6. Newborns with severe narrowing are cyanotic.
7. If pulmonary stenosis is severe, HF occurs.
8. Signs and symptoms of decreased cardiac output may occur.
9. Management: Dilation of the narrowed valve may be done during cardiac catheterization.
10. Surgical management:
    a. In infants: Transventricular (closed) valvotomy procedure
    b. In children: Pulmonary valvotomy with cardiopulmonary bypass

V. Defects with Decreased Pulmonary Blood Flow

A. Description
1. Obstructed pulmonary blood flow and an anatomical defect (ASD or VSD) between the right and left sides of the heart are present.
2. Pressure on the right side of the heart increases, exceeding pressure on the left side, which allows desaturated blood to shunt right to left, causing desaturation in the left side of the heart and in the systemic circulation.
3. Typically hypoxemia and cyanosis appear.

B. Tetralogy of Fallot
1. Tetralogy of Fallot includes four defects—VSD, pulmonary stenosis, overriding aorta, and right ventricular hypertrophy.
2. If pulmonary vascular resistance is higher than systemic resistance, the shunt is from right to left; if systemic resistance is higher than pulmonary resistance, the shunt is from left to right.
3. Infants
    a. An infant may be acutely cyanotic at birth or may have mild cyanosis that progresses over the first year of life as the pulmonic stenosis worsens.
    b. A characteristic murmur is present.
    c. Acute episodes of cyanosis and hypoxia (hypercyanotic episode), called *blue spells* or *tet spells*, occur when the infant's oxygen requirements exceed the blood supply, such as during periods of crying, feeding, or defecating (see Clinical Judgment: Take Action Box).
4. Children: With increasing cyanosis, squatting, clubbing of the fingers, and poor growth may occur.
    a. Squatting is a compensatory mechanism to facilitate increased return of blood flow to the heart for oxygenation.
    b. Clubbing is an abnormal enlargement in the distal phalanges, seen in the fingers.
5. Surgical management: Palliative shunt
    a. The shunt increases pulmonary blood flow and increases oxygen saturation in infants who cannot undergo primary repair.
    b. The shunt provides blood flow to the pulmonary arteries from the left or right subclavian artery.
6. Surgical management: Complete repair
    a. Complete repair usually is performed in the first year of life.
    b. The repair requires a median sternotomy and cardiopulmonary bypass.

C. Tricuspid atresia
1. Tricuspid atresia is failure of the tricuspid valve to develop.
2. No communication exists from the right atrium to the right ventricle.
3. Blood flows through an ASD or a patent foramen ovale to the left side of the heart and through a VSD to the right ventricle and out to the lungs.
4. The defect often is associated with pulmonic stenosis and transposition of the great arteries.
5. The defect results in complete mixing of unoxygenated and oxygenated blood in the left side of the heart, resulting in systemic desaturation, pulmonary obstruction, and decreased pulmonary blood flow.
6. Cyanosis, tachycardia, and dyspnea are seen in the newborn.
7. Older children exhibit signs of chronic hypoxemia and clubbing.
8. Management: If the ASD is small, the defect may be closed during cardiac catheterization; otherwise, surgery is needed.

Clubbing is symptomatic of chronic hypoxia. Peripheral circulation is diminished, and oxygenation of vital organs and tissues is compromised.

CLINICAL JUDGMENT: TAKE ACTION

The nurse is assisting with a blood draw on an infant with tetralogy of Fallot. The infant is crying uncontrollably because of the trauma. Respirations become deep and rapid, and the infant becomes cyanotic. The nurse recognizes that the infant is experiencing a hypercyanotic episode and takes the following actions:

- Calms the infant and minimizes stimuli
- Places the infant in a knee-chest position
- Contacts the primary health care provider or cardiologist
- Administers 100% oxygen as prescribed
- Administers morphine sulfate as prescribed
- Administers fluids intravenously as prescribed
- Documents the occurrence, actions taken, and the infant's response

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

VI. Mixed Defects

A. Description

1. Fully saturated systemic blood flow mixes with the desaturated blood flow, causing desaturation of the systemic blood flow.
2. Pulmonary congestion occurs and cardiac output decreases.
3. Signs of HF are present; symptoms vary with the degree of desaturation.

B. Hypoplastic left heart syndrome

1. Underdevelopment of the left side of the heart occurs, resulting in a hypoplastic left ventricle and aortic atresia.
2. Mild cyanosis and signs of HF occur until the ductus arteriosus closes; then progressive deterioration with cyanosis and decreased cardiac output are seen, leading to cardiovascular collapse.
3. Without intervention the defect is fatal in the first few months of life.
4. Surgical treatment
   a. Surgical treatment is necessary; transplantation in the newborn period may be considered.
   b. In the preoperative period, the newborn requires mechanical ventilation and a continuous infusion of prostaglandin E_1 to maintain ductal patency, ensuring adequate systemic blood flow.

C. Transposition of the great arteries or transposition of the great vessels

1. The pulmonary artery leaves the left ventricle, and the aorta exits from the right ventricle.
2. No communication exists between the systemic and pulmonary circulation.
3. Infants with minimal communication are severely cyanotic at birth.
4. Infants with large septal defects or a patent ductus arteriosus may be less severely cyanotic but may have symptoms of HF.
5. Cardiomegaly is evident a few weeks after birth.
6. Nonsurgical management
   a. Prostaglandin E_1 may be initiated to keep the ductus arteriosus open and to improve blood mixing temporarily.
   b. Balloon atrial septostomy during cardiac catheterization may be performed to increase mixing from both sides of the heart and to maintain cardiac output over a longer period.
7. Surgical management: The arterial switch procedure reestablishes normal circulation with the left ventricle acting as the systemic pump and creation of a new aorta.

D. Total anomalous pulmonary venous connection

1. The defect is a failure of the pulmonary veins to join the left atrium.
2. The defect results in mixed blood being returned to the right atrium and shunted from the right to the left through an ASD.
3. The right side of the heart hypertrophies, whereas the left side of the heart may remain small.
4. Signs and symptoms of HF develop.
5. Cyanosis worsens with pulmonary vein obstruction; when obstruction occurs, the infant's condition deteriorates rapidly.
6. Surgical management
   a. Corrective repair is performed in early infancy.
   b. The pulmonary vein is anastomosed to the left atrium, the ASD is closed, and the anomalous pulmonary venous connection is ligated.

E. Truncus arteriosus

1. Truncus arteriosus is failure of normal septation and division of the embryonic bulbar trunk into the pulmonary artery and the aorta, resulting in a single vessel that overrides both ventricles.
2. Blood from both ventricles mixes in the common great artery, causing desaturation and hypoxemia.
3. A characteristic murmur is present.
4. The infant exhibits moderate to severe HF and variable cyanosis, poor growth, and activity intolerance.
5. Surgical management: Corrective surgical repair is performed in the first few months of life.

VII. Interventions: Cardiovascular Defects (Box 37.4)

VIII. Cardiac Catheterization

A. Description

1. Invasive diagnostic procedure to determine cardiac defects
2. Provides information about oxygen saturation of blood in great vessels and heart chambers
3. May be done for diagnostic, interventional, or electrophysiological reasons
4. May be carried out on an outpatient basis
5. Risks include hemorrhage from the entry site, clot formation and subsequent blockage distally, and transient dysrhythmias.
6. General anesthesia is usually unnecessary.
7. See Chapter 53 for additional information about this procedure.

B. Preprocedure nursing interventions

1. Assess accurate height and weight, because this helps with the selection of the correct catheter size and correct medication calculation/dosing.
2. Obtain a history of the presence of allergic reactions to iodine.
3. Assess for symptoms of infection, including a diaper rash.
4. Assess and mark bilateral pulses, including the dorsalis pedis and posterior tibial (need to check pulses distal to catheter insertion site).
5. Assess baseline oxygen saturation.

Telegram & Insta: NCLEX_RN_Edu

BOX 37.4 Interventions for Cardiovascular Defects

- Monitor for signs of a defect in the infant or child.
- Monitor vital signs closely.
- Monitor respiratory status for the presence of nasal flaring, use of accessory muscles, and for signs of impending respiratory distress, and notify the pediatrician if any changes occur.
- Auscultate breath sounds for crackles, rhonchi, or wheezes.
- If respiratory effort is increased, place the child in a reverse Trendelenburg's position, elevating the head and upper body, to decrease the work of breathing.
- Administer humidified oxygen as prescribed.
- Provide endotracheal tube and ventilator care if necessary as prescribed.
- Monitor for hypercyanotic spells and intervene immediately if they occur.
- Assess for signs of HF, such as periorbital edema or dependent edema in the hands and feet.
- Assess peripheral pulses.
- Maintain fluid restriction if prescribed.
- Monitor intake and output, and notify the pediatrician if a decrease in urine output occurs.
- Obtain daily weight.
- Provide adequate nutrition (high calorie requirements) as prescribed.
- Administer medications as prescribed.
- Plan interventions to allow maximal rest for the child; keep the child as stress-free as possible.
- Prepare the child and parents for cardiac catheterization, if appropriate.

6. Familiarize the parents and child with hospital procedures and equipment.
7. Educate the child, if age appropriate, and the parents about the procedure.
8. Allow the parents and child to verbalize feelings and concerns regarding the procedure and the disorder.

C. Postprocedure nursing interventions

1. Monitor findings on the cardiac monitor and oxygen saturation for 4 hours after procedure.
2. Assess pulses below the catheter site for presence, equality, and symmetry.
3. Assess the temperature and color of the affected extremity and report coolness, which may indicate arterial obstruction.
4. Monitor vital signs frequently, usually every 15 minutes 4 times, every half-hour 4 times, and then every hour 4 times.
5. Assess the pressure dressing for intactness and signs of hemorrhage.
6. Check the bedsheets under the extremity for blood, which indicates bleeding from the entry site.
7. If bleeding is present, apply continuous, direct pressure at or directly above the cardiac catheter entry site and report it immediately.
8. Immobilize the affected extremity in a flat position for at least 4 to 6 hours for venous entry site and 6 to 8 hours for arterial entry site as prescribed.
9. Hydrate the child via the oral or intravenous route or both routes as prescribed.
10. Administer acetaminophen or ibuprofen for pain or discomfort as prescribed.
11. Prepare the parents and child, if appropriate, for surgery.

D. Discharge teaching for the child and parents

1. Remove the dressing on the day after the procedure, and cover the site with an adhesive bandage for a minimum of 2 days. A new bandage would be applied each day.
2. Keep the site clean and dry.
3. Avoid tub baths for 2 to 3 days. May shower one day postoperatively.
4. Observe for redness, edema, drainage, bleeding, and fever, and report any of these signs immediately.
5. Avoid strenuous activity, if applicable.
6. The child may return to school, if appropriate.
7. Provide a diet as tolerated.
8. Administer acetaminophen or ibuprofen for pain, discomfort, or fever.
9. Keep follow-up appointment with the pediatrician.

IX. Cardiac Surgery

A. Postoperative interventions

1. Monitor vital signs frequently, especially temperature, and notify the surgeon if fever occurs.
2. Monitor for signs of sepsis such as fever, chills, diaphoresis, lethargy, and altered levels of consciousness.
3. Maintain strict aseptic technique.
4. Monitor lines, tubes, or catheters that are in place, and monitor for signs and symptoms of infection.
5. Assess for signs of discomfort such as irritability, restlessness, or changes in heart rate, respiratory rate, and blood pressure.
6. Administer pain medications as prescribed.
7. Administer antibiotics and antipyretics as prescribed.
8. Promote rest and sleep periods.
9. Facilitate parent-child contact as soon as possible.

B. Postoperative home care (Box 37.5)

X. Rheumatic Fever

A. Description

1. Rheumatic fever is an inflammatory autoimmune disease that affects the connective tissues of the heart, joints, skin (subcutaneous tissues), blood vessels, and central nervous system.
2. The most serious complication is rheumatic heart disease, which affects the cardiac valves, particularly the mitral valve.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 37.5 Home Care after Cardiac Surgery

- Omit play outside for several weeks as prescribed.
- Avoid activities in which the child could fall and be injured, such as bike riding, for 2 to 4 weeks.
- Avoid crowds for 2 weeks after discharge.
- Follow a no-added-salt diet, if prescribed.
- Do not add any new foods to the infant's diet. (If an allergy exists to the new food, the manifestations may be interpreted as a postoperative complication.)
- Do not place creams, lotions, or powders on the incision until completely healed.
- The child may return to school usually the third week after discharge, starting with half-days.
- The child would not participate in physical education for 2 months.
- Discipline the child normally.
- The 2-week follow-up is important.
- Avoid immunizations, invasive procedures, and dental visits for 2 months; after this time period, the immunization schedule and dental visits need to be resumed.
- The child needs to have a dental visit every 6 months after age 3 years; inform the dentist of the cardiac problem so that antibiotics can be prescribed if necessary.
- Call the pediatrician if coughing, tachypnea, cyanosis, vomiting, diarrhea, anorexia, pain, or fever occurs, or if any swelling, redness, or drainage occurs at the site of the incision.

3. Rheumatic fever manifests 2 to 6 weeks after an untreated or partially treated group A beta-hemolytic streptococcal infection of the upper respiratory tract.
4. Jones criteria are used to help determine the diagnosis (Box 37.6).

B. Assessment (Fig. 37.1)

1. Fever: Low-grade fever that spikes in the late afternoon
2. Elevated anti–streptolysin O titer
3. Elevated erythrocyte sedimentation rate
4. Elevated C-reactive protein level
5. Aschoff bodies (lesions): Found in the heart, blood vessels, brain, and serous surfaces of the joints and pleura

Assessment of a child with suspected rheumatic fever includes inquiring about a recent sore throat, because rheumatic fever manifests 2 to 6 weeks after an untreated or partially treated group A beta-hemolytic streptococcal infection of the upper respiratory tract.

C. Interventions

1. Assess vital signs.
2. Control joint pain and inflammation with massage and alternating hot and cold applications as prescribed.
3. Provide bed rest during the acute febrile phase.
4. Limit physical exercise in a child with carditis.
5. Administer antibiotics as prescribed.

BOX 37.6 Jones Criteria for Diagnosis of Rheumatic Fever

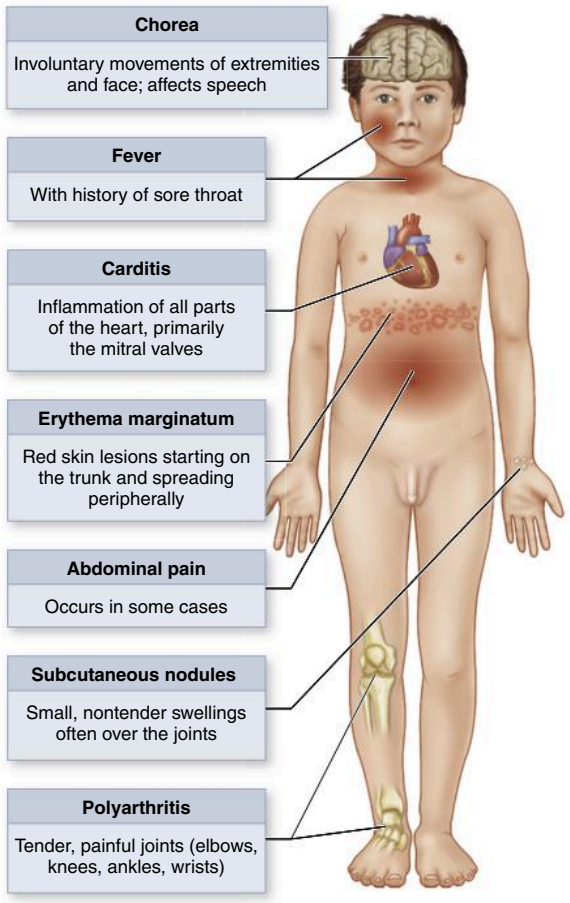
Major Criteria

- Carditis
- Arthritis
- Chorea
- Erythema marginatum
- Subcutaneous nodules

Minor Criteria

- Fever
- Polyarthralgia
- Elevated erythrocyte sedimentation rate or positive C-reactive protein level
- Prolonged PR interval on electrocardiogram

Note: For making a diagnosis, two major or one major and two minor manifestations must be accompanied by supporting evidence of a preceding streptococcal infection (positive throat culture for group A *Streptococcus* and an elevated or increasing anti–streptolysin O titer).



Chorea
Involuntary movements of extremities and face; affects speech
Fever
With history of sore throat
Carditis
Inflammation of all parts of the heart, primarily the mitral valves
Erythema marginatum
Red skin lesions starting on the trunk and spreading peripherally
Abdominal pain
Occurs in some cases
Subcutaneous nodules
Small, nontender swellings often over the joints
Polyarthritis
Tender, painful joints (elbows, knees, ankles, wrists)

FIG. 37.1 Clinical manifestations of rheumatic fever.

6. Administer salicylates and antiinflammatory agents as prescribed; these medications would not be administered before the diagnosis is confirmed, because the medications mask the polyarthritis.
7. Initiate seizure precautions if the child is experiencing chorea.
8. Instruct the parents about the importance of follow-up and the need for antibiotic prophylaxis

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

for dental work, infection, and invasive procedures.

9. Advise the child to inform the parents if anyone in school develops a streptococcal throat infection.

XI. Kawasaki Disease

A. Description

1. Kawasaki disease, also known as *mucocutaneous lymph node syndrome,* is an acute systemic inflammatory illness.
2. The cause is unknown, but it may be associated with an infection from an organism or toxin.
3. Cardiac involvement is the most serious complication; aneurysms can develop.

B. Assessment

1. Acute stage
   - **a.** Fever
   - **b.** Conjunctival hyperemia
   - **c.** Mucositis (cracked red lips and a "strawberry tongue")
   - **d.** Extremity changes, including swelling of the hands and feet and erythema of the palms and soles
   - **e.** Rash
   - **f.** Enlargement of cervical lymph nodes
   - **g.** Increased irritability
   - **h.** Arthritis
   - **i.** Cardiovascular findings, including tachycardia and gallop sounds
2. Subacute stage: Begins with resolution of fever and continues until outward clinical manifestations have resolved
   - **a.** Cracking lips and fissures
   - **b.** Desquamation of the skin on the tips of the fingers and toes
   - **c.** Joint pain
   - **d.** Cardiac manifestations
   - **e.** Thrombocytosis (hypercoagulability)
3. Convalescent stage: Child appears normal, but signs of inflammation may be present, and laboratory values may be abnormal.

C. Interventions

1. Monitor temperature frequently.
2. Assess heart sounds and heart rate and rhythm.
3. Assess extremities for edema, redness, and desquamation.
4. Examine eyes for conjunctivitis.
5. Monitor mucous membranes for inflammation.
6. Monitor strict intake and output.
7. Administer soft foods and liquids that are neither too hot nor too cold.
8. Weigh child daily.
9. Provide passive range-of-motion exercises to facilitate joint movement.
10. Administer acetylsalicylic acid (moderate to high dose) as prescribed for its antipyretic and antiplatelet effects (additional anticoagulation may be necessary if aneurysms are present).
11. Administer immunoglobulin (IVIG) intravenously (high dose) as prescribed to reduce the duration of the fever and the incidence of coronary artery lesions and aneurysms; intravenous immunoglobulin is a blood product, so blood precautions when administering it are warranted.
12. Parent education (Box 37.7)

BOX 37.7 Parent Education for Kawasaki Disease

- Follow-up care is essential to recovery.
- Signs and symptoms of Kawasaki disease include the following:
  - Irritability that may last for 2 months after the onset of symptoms
  - Peeling of the hands and feet
  - Pain in the joints that may persist for several weeks
  - Stiffness in the morning, after naps, and in cold temperatures
- Record the temperature (because fever is expected) until the child has been afebrile for several days.
- Notify the pediatrician if the temperature is 101° F (38.3° C) or higher.
- Salicylates such as acetylsalicylic acid (aspirin) may be prescribed.
- Signs of aspirin toxicity include tinnitus, headache, vertigo, and bruising; do not administer aspirin or aspirin-containing products if the child has been exposed to chicken pox or the flu.
- Signs and symptoms of bleeding include epistaxis (nosebleeds), hemoptysis (coughing up blood), hematemesis (vomiting up blood), hematuria (blood in urine), melena (blood in stool), and bruises on the body.
- Signs and symptoms of cardiac complications include chest pain or tightness (older children), cool and pale extremities, abdominal pain, nausea and vomiting, irritability, restlessness, and uncontrollable crying.
- The child needs to avoid contact sports, if age appropriate, if taking aspirin or anticoagulants.
- Avoid administration of measles, mumps, and rubella (MMR) or varicella vaccine to the child for 11 months after intravenous immunoglobulin therapy, if appropriate.

PRACTICE QUESTIONS

1. The nurse is monitoring an infant with congenital heart disease closely for signs of heart failure (HF). The nurse would assess the infant for which **early** sign of HF?
   1. Pallor
   2. Cough
   3. Tachycardia
   4. Slow and shallow breathing

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. The nurse reviews the laboratory results for a child with a suspected diagnosis of rheumatic fever, knowing that which laboratory study would assist in confirming the diagnosis?
   1. Immunoglobulin
   2. Red blood cell count
   3. White blood cell count
   4. Anti–streptolysin O titer

3. On assessment of a child admitted with a diagnosis of acute-stage Kawasaki disease, the nurse expects to note which clinical manifestation of the acute stage of the disease?
   1. Cracked lips
   2. Normal appearance
   3. Conjunctival hyperemia
   4. Desquamation of the skin

4. The nurse provides home care instructions to the parents of a child with heart failure regarding the procedure for administration of digoxin. Which statement made by the parent indicates the **need for further instruction**?
   1. "I will not mix the medication with food."
   2. "If more than one dose is missed, I will call the pediatrician."
   3. "I will take my child's pulse before administering the medication."
   4. "If my child vomits after medication administration, I will repeat the dose."

5. The nurse is closely monitoring the intake and output of an infant with heart failure who is receiving diuretic therapy. The nurse would use which **most appropriate** method to assess the urine output?
   1. Weighing the diapers
   2. Inserting a urinary catheter
   3. Comparing intake with output
   4. Measuring the amount of water added to formula

6. The clinic nurse reviews the record of a child just seen by the pediatrician and diagnosed with suspected aortic stenosis. The nurse expects to note documentation of which clinical manifestation specifically found in this disorder?
   1. Pallor
   2. Hyperactivity
   3. Activity intolerance
   4. Gastrointestinal disturbances

7. The nurse has provided home care instructions to the parents of a child who is being discharged after cardiac surgery. Which statement made by the parents indicates a **need for further instruction?**
   1. "A balance of rest and activity is important."
   2. "We can apply lotion or powder to the incision if it is itchy."
   3. "Activities in which our child could fall need to be avoided for 2 to 4 weeks."
   4. "Large crowds of people need to be avoided for at least 2 weeks after surgery."

8. A child with rheumatic fever will be arriving at the nursing unit for admission. On admission assessment, the nurse would ask the parents which question to elicit assessment information specific to the development of rheumatic fever?
   1. "Has the child complained of back pain?"
   2. "Has the child complained of headaches?"
   3. "Has the child had any nausea or vomiting?"
   4. "Did the child have a sore throat or fever within the last 2 months?"

9. A pediatrician has prescribed oxygen as needed for an infant with heart failure. Which situation would likely increase the oxygen demand, requiring the nurse to administer oxygen to the infant?
   1. During sleep
   2. When changing the infant's diapers
   3. When a parent is holding the infant
   4. When drawing blood for electrolyte level testing

10. Assessment findings of an infant admitted to the hospital reveal a machinery-like murmur on auscultation of the heart and signs of heart failure. The nurse reviews congenital cardiac anomalies and identifies the infant's condition as which disorder? **Refer to figure** (the circled area) to determine the condition.

   1. Aortic stenosis
   2. Atrial septal defect
   3. Patent ductus arteriosus
   4. Ventricular septal defect

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 3

Rationale: HF is the inability of the heart to pump a sufficient amount of blood to meet the oxygen and metabolic needs of the body. The early signs of HF include tachycardia, tachypnea, profuse scalp sweating, fatigue and irritability, sudden weight gain, and respiratory distress. A cough may occur in HF as a result of mucosal swelling and irritation, but it is not an early sign. Pallor may be noted in an infant with HF, but it is not an early sign.

Test-Taking Strategy: Note the **strategic word,** *early*. Think about the physiology and the effects on the heart when fluid overload occurs. These concepts will assist in directing you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 969-970.

2. *Answer:* 4

Rationale: Rheumatic fever is an inflammatory autoimmune disease that affects the connective tissues of the heart, joints, skin (subcutaneous tissues), blood vessels, and central nervous system. A diagnosis of rheumatic fever is confirmed by the presence of two major manifestations or one major and two minor manifestations from the Jones criteria. In addition, evidence of a recent streptococcal infection is confirmed by a positive anti–streptolysin O titer, Streptozyme assay, or anti-DNase B assay. Options 1, 2, and 3 would not help confirm the diagnosis of rheumatic fever.

Test-Taking Strategy: Focus on the **subject,** definitive diagnosis of rheumatic fever. Recalling that rheumatic fever characteristically is associated with streptococcal infection will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 996-997.

3. *Answer:* 3

Rationale: Kawasaki disease, also known as *mucocutaneous lymph node syndrome*, is an acute systemic inflammatory illness. In the acute stage, the child has a fever, conjunctival hyperemia, red throat, swollen hands, rash, and enlargement of the cervical lymph nodes. In the subacute stage, cracking lips and fissures, desquamation of the skin on the tips of the fingers and toes, joint pain, cardiac manifestations, and thrombocytosis occur. In the convalescent stage, the child appears normal, but signs of inflammation may be present.

Test-Taking Strategy: Focus on the **subject,** the acute stage of Kawasaki disease. Option 2 can be eliminated first, because a normal appearance is not likely in the acute stage. From the remaining options, focusing on the words *acute stage* in the question will assist in directing you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 998.

4. *Answer:* 4

Rationale: Digoxin is a cardiac glycoside. The parents need to be instructed that if the child vomits after digoxin is administered, they are not to repeat the dose. Options 1, 2, and 3 are accurate instructions regarding the administration of this medication. In addition, the parents need to be instructed that if a dose is missed and the missed dose is not identified until 4 hours later, the dose would not be administered.

Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. General knowledge regarding digoxin administration will assist in eliminating option 2. Principles related to administering medications to children will assist in eliminating option 1. From the remaining options, select the correct option because if the child vomits, it would be difficult to determine whether the medication also was vomited or was absorbed by the body.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 975.

5. *Answer:* 1

Rationale: Heart failure is the inability of the heart to pump a sufficient amount of blood to meet the oxygen and metabolic needs of the body. The most appropriate method for assessing urine output in an infant receiving diuretic therapy is to weigh the diapers. Comparing intake with output would not provide an accurate measure of urine output. Measuring the amount of water added to formula is unrelated to the amount of output. Although urinary catheter drainage is most accurate in determining output, it is not the most appropriate method in an infant and places the infant at risk for infection.

Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Eliminate options 3 and 4 first because they are **comparable or alike** and will not provide an indication of urine output. Noting the **strategic words** will direct you to the correct option from the remaining options.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 273.

6. *Answer:* 3

Rationale: Aortic stenosis is a narrowing or stricture of the aortic valve, causing resistance to blood flow in the left ventricle, decreased cardiac output, left ventricular hypertrophy, and pulmonary vascular congestion. A child with aortic stenosis shows signs of activity intolerance, chest pain, and dizziness when standing for long periods. Pallor may be noted, but it is not specific to this type of disorder alone. Options 2 and 4 are not related to this disorder.

Test-Taking Strategy: Focus on the **subject,** the characteristics of aortic stenosis. Options 2 and 4 can be eliminated first, because they are not associated with a cardiac disorder. From the remaining options, noting the word *specifically* in the question will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 981.

7. *Answer:* 2

Rationale: The parents need to be instructed that lotions and powders would not be applied to the incision site after cardiac surgery. Lotions and powders can irritate the surrounding

Telegram & Insta: NCLEX_RN_Edu

skin, which could lead to skin breakdown and subsequent infection of the incision site. Options 1, 3, and 4 are accurate instructions regarding home care after cardiac surgery.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Using general principles related to postoperative incisional site care will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1252-1253.

8. *Answer:* 4
Rationale: Rheumatic fever is an inflammatory autoimmune disease that affects the connective tissues of the heart, joints, skin (subcutaneous tissues), blood vessels, and central nervous system. Rheumatic fever characteristically manifests 2 to 6 weeks after an untreated or partially treated group A beta-hemolytic streptococcal infection of the upper respiratory tract. Initially, the nurse determines whether the child had a sore throat or an unexplained fever within the past 2 months. Options 1, 2, and 3 are unrelated to rheumatic fever.
Test-Taking Strategy: Focus on the **subject,** the pathophysiology and etiology associated with rheumatic fever. Also, note the similarity between the words *rheumatic fever* in the question and the word *fever* in the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 996.

9. *Answer:* 4
Rationale: Heart failure (HF) is the inability of the heart to pump a sufficient amount of blood to meet the oxygen and metabolic needs of the body. Crying exhausts the limited energy supply, increases the workload of the heart, and increases the oxygen demands. Oxygen administration may be prescribed for stressful periods, especially during bouts of crying or invasive procedures. Options 1, 2, and 3 are unlikely to produce crying in the infant.
Test-Taking Strategy: Focus on the **subject,** the need to administer oxygen to the infant with HF, and recall the situations that would place stress and an increased workload on the heart; this would direct you to the correct option. Drawing blood is an invasive procedure that would probably cause the infant to cry.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 973, 1014.

10. *Answer:* 3
Rationale: A patent ductus arteriosus is failure of the fetal ductus arteriosus (artery connecting the aorta and the pulmonary artery) to close. A characteristic machinery-like murmur is present, and the infant may show signs of heart failure. Aortic stenosis is a narrowing or stricture of the aortic valve. Atrial septal defect is an abnormal opening between the atria. Ventricular septal defect is an abnormal opening between the right and left ventricles.
Test-Taking Strategy: Focus on the **subject,** the congenital cardiac anomaly and the location of the defect. Recalling the anatomical locations in the heart will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 314.

CHAPTER 38

Renal and Genitourinary Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

PRIORITY CONCEPTS Elimination; Inflammation

I. Urinary Tract Infection (UTI)

A. Bacterial invasion of the urinary tract from flora from the skin or gastrointestinal tract

B. Uncircumcised infants are more likely to develop a UTI than a circumcised infant; see: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1477524/

C. Hygiene (wiping from front to back) is important in children to prevent this problem.

D. Children may experience asymptomatic bacteriuria, so if there is a suspicion of infection in the urinary tract, they need to be screened and treated accordingly.

E. See Chapter 55 for additional information.

II. Glomerulonephritis

A. Description

1. *Glomerulonephritis* refers to a group of kidney disorders characterized by inflammatory injury in the glomerulus, most of which are caused by an immunological reaction.
2. The disorder results in proliferative and inflammatory changes within the glomerular structure.
3. Destruction, inflammation, and sclerosis of the glomeruli of the kidneys occur.
4. Inflammation of the glomeruli results from an antigen-antibody reaction produced by an infection elsewhere in the body.
5. Loss of kidney function develops.

B. Causes

1. Immunological diseases
2. Autoimmune diseases
3. Antecedent group A beta-hemolytic -hemolytic streptococcal infection of the pharynx or skin
4. History of pharyngitis or tonsillitis 1 to 2 weeks before symptoms or history of streptococcal infection of the skin 3 to 6 weeks before symptoms

C. Types

1. Acute: Occurs 1 to 2 weeks after a streptococcal infection or parent reports the child has a history of streptococcal infection of the skin 3 to 6 weeks before symptoms
2. Chronic: May occur after the acute phase or slowly over time

D. Complications

1. Kidney failure
2. Hypertensive encephalopathy
3. Pulmonary edema
4. Heart failure
5. Seizures

E. Assessment (Box 38.1)

BOX 38.1 Assessment Findings in Glomerulonephritis

- Periorbital and facial edema that is more prominent in the morning
- Anorexia
- Decreased urinary output
- Cloudy, smoky, brown-colored (cola-colored) urine (hematuria)
- Pallor, irritability, lethargy
- In an older child: Headaches, abdominal or flank pain, dysuria
- Hypertension
- Proteinuria that produces a persistent and excessive foam in the urine
- Azotemia
- Increased blood urea nitrogen and creatinine levels
- Increased anti–streptolysin O titer (used to diagnose disorders caused by streptococcal infections)

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: ANALYZE CUES

The nurse arrives at 0700, performs an assessment on an 8-year-old child with glomerulonephritis, and notes the following:

Nurse's Notes

Periorbital and facial edema, generalized edema
Hand and neck veins distended
Weight 37.2 kg (82 lb) increased from 34.5 kg (76 lb) recorded 24 hrs ago
Reports anorexia and some abdominal discomfort; not wanting to eat breakfast
Urinary output 30 mL since last evening; cloudy and cola-colored
Pale and sleepy
Temperature 99.2° F (37.3° C), pulse 122 beats per minute and bounding, dyspneic, respirations 24 breaths per minute, blood pressure 140/98 mm Hg

The nurse analyzes the assessment findings, determines that the child is experiencing fluid volume overload, and notifies the primary health care provider for prescriptions, which may include fluid and sodium restriction and the administration of diuretics.

F. Interventions (see Clinical Judgment: Analyze Cues Box)

1. Monitor vital signs, intake and output, and characteristics of urine.
2. Measure daily weights at the same time of day, using the same scale, and wearing the same clothing.
3. Limit activity; provide safety measures.
4. Diet restrictions of **sodium** depend on the stage and severity of the disease, especially the extent of the edema; in addition, **potassium** may be restricted during periods of **oliguria.**
5. Monitor for complications (e.g., kidney failure, hypertensive encephalopathy, seizures, pulmonary edema, fluid volume overload, heart failure).
6. Administer diuretics (if significant edema and fluid overload are present), antihypertensives (for hypertension), and antibiotics (to a child with evidence of persistent streptococcal infections) as prescribed.
7. Initiate seizure precautions and administer anticonvulsants as prescribed for seizures associated with hypertensive encephalopathy.
8. Instruct parents to report signs of bloody urine, headache, or edema.
9. Instruct parents that the child needs to obtain appropriate and immediate treatment for infections, specifically for sore throats, upper respiratory infections, and skin infections.

! Measuring the daily weight and assessing for changes is the most useful and effective measure for determining fluid balance.

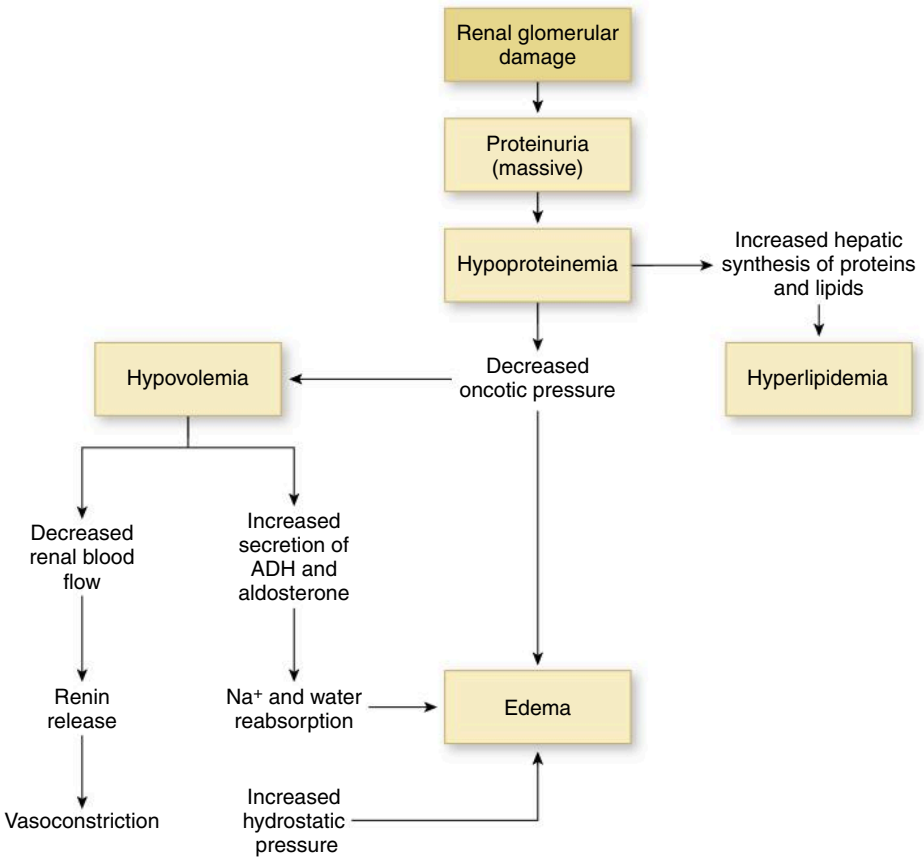

FIG. 38.1 Sequence of events in nephrotic syndrome. *ADH*, Antidiuretic hormone; *Na*+, sodium.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 38.2 Assessment Findings in Nephrotic Syndrome

- Weight gain in the child
- Periorbital and facial edema most prominent in the morning
- Leg, ankle, labial, or scrotal edema
- Decrease in urine output; urine dark and frothy
- Ascites (fluid in abdominal cavity)
- Blood pressure normal or slightly decreased
- Lethargy, anorexia, and pallor
- Massive proteinuria
- Decreased serum protein (hypoproteinemia) and elevated serum lipid levels

BOX 38.3 Assessment Findings in Hemolytic-Uremic Syndrome

- Vomiting
- Irritability
- Lethargy
- Marked pallor
- Hemorrhagic manifestations: bruising, petechiae, jaundice, bloody diarrhea
- Oliguria or anuria
- Central nervous system involvement: seizures, stupor, coma

III. Nephrotic Syndrome

A. Description

1. Nephrotic syndrome is a kidney disorder characterized by massive proteinuria, hypoalbuminemia (hypoproteinemia), hyperlipidemia, and edema (Fig. 38.1).
2. The primary objectives of therapeutic management are to reduce the excretion of urinary protein, maintain protein-free urine, reduce edema, prevent infection, and minimize complications.

B. Assessment (Box 38.2)

The classic manifestations of nephrotic syndrome are massive proteinuria, hypoalbuminemia, hyperlipidemia, and edema.

C. Interventions

1. Monitor vital signs, intake and output, and daily weights.
2. Monitor urine for specific gravity and protein.
3. Monitor for edema.
4. Nutrition: A regular diet without added salt may be prescribed if the child is in remission; sodium is restricted during periods of massive edema (fluids may also be restricted).
5. Corticosteroid therapy is prescribed as soon as the diagnosis has been determined; monitor the child closely for signs of infection and other adverse effects of corticosteroids (see Chapter 48).
6. Immunosuppressant therapy may be prescribed to reduce the relapse rate and induce long-term remission, or, if the child is unresponsive to corticosteroid therapy, immunosuppressant therapy may be administered along with the corticosteroid.
7. Diuretics may be prescribed to reduce edema.
8. Plasma expanders such as salt-poor human albumin may be prescribed for a severely edematous child.
9. Instruct parents about testing the urine for protein, administering medications, the side effects of medications, and general care of the child.
10. Instruct parents on the signs of infection and the need to avoid contact with other children who may be infectious.

IV. Hemolytic-Uremic Syndrome

A. Description

1. Hemolytic-uremic syndrome is thought to be associated with bacterial toxins, chemicals, and viruses that cause acute kidney injury in children.
2. It occurs primarily in infants and small children 6 months to 5 years old.
3. Clinical features include acquired hemolytic anemia, thrombocytopenia, kidney injury, and central nervous system symptoms.

B. Assessment

1. Triad of anemia, thrombocytopenia, and kidney failure (Box 38.3)
2. Proteinuria, hematuria, and presence of urinary casts
3. Blood urea nitrogen and serum creatinine levels elevated; hemoglobin and hematocrit levels decreased; an increased or high reticulocyte count

C. Interventions

1. Hemodialysis or peritoneal dialysis may be prescribed if a child's renal status worsens (dialysate solution is prescribed to meet the child's electrolyte needs). The nurse should inform the PHCP if the child becomes anuric, if urine output decreases, if the child's vital signs change, or if the child shows other signs of a worsening condition, such as shortness of breath.
2. Strict monitoring of fluid balance is necessary; fluid restrictions may be prescribed if the child is anuric.
3. Institute measures to prevent infection.
4. Provide adequate nutrition.
5. Other treatments include medications to treat manifestations and the administration of blood products to treat severe anemia (administered with caution to prevent fluid overload).

V. Vesicoureteral reflux (VUR)

A. Description

1. Urine flow is abnormal and flows from the bladder back up into the ureters and the kidneys; this can cause infections and kidney damage.
2. In many cases, children grow out of this condition, but if the condition is severe, surgery may be needed to protect the kidneys.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. The cause is most likely due to an abnormal flap valve where the ureter joins the bladder, allowing the backflow of urine; this is known as primary vesicoureteral reflux.
4. Secondary vesicoureteral reflux could also be a cause, and this refers to a blockage at the bladder that causes the urine to backflow into the ureters from the bladder.
5. Those most likely to get VUR are those with birth defects such as bladder exstrophy, those with parents or siblings who have the condition, and those with an abnormal bladder function, as seen with spina bifida.
6. Abdominal ultrasound, voiding cystourethrogram, or other urodynamic studies may be done to diagnose the condition; laboratory studies and a urinalysis may be done to determine renal function.

B. Assessment
1. Findings depend on the age of the child, but urinary tract infections (UTIs) caused by bacteria are a common finding.
2. Bloody urine, cloudy urine with a foul odor
3. Difficulty urinating (urgency, wetting pants or the bed, leakage of urine)
4. Abdominal mass (swollen bladder)
5. Anorexia, poor weight gain
6. Constipation

C. Interventions
1. Treatment depends on the severity of the condition.
2. Antibiotics may be prescribed to treat UTIs and prevent kidney infections.
3. Deflux procedure, in which a gel-like mixture is injected into the wall of the bladder where the ureter joins the bladder; this acts as a valve to help prevent the flow of urine backward toward the kidney.
4. Surgery to repair the valve between the bladder and ureter
5. Emphasize to parents the importance of antibiotics, if prescribed; increased fluids, avoiding juices and soft drinks because they can cause bladder irritation; and placement of a warm blanket or towel over the child's abdomen to relieve pain or pressure.

VI. Enuresis

A. Description
1. *Enuresis* refers to a condition in which a child is unable to control bladder function, even though the child has reached an age at which control of voiding is expected or the child has successfully completed a bladder control program.
2. A child does not have control over this condition.

B. Primary enuresis: Wetting that occurs in a child who has not fully mastered toilet training

C. Nighttime (nocturnal) enuresis
1. Nighttime (nocturnal) enuresis is bedwetting in a child who has never been dry for extended periods.
2. The condition is common in children, and most children eventually outgrow bedwetting without therapeutic intervention.
3. The child is unable to sense a full bladder and does not awaken to void.
4. The child may have delayed maturation of the central nervous system.
5. The child needs to be evaluated for any pathological causes before the diagnosis of nighttime (nocturnal) enuresis is made.

D. Daytime (diurnal) enuresis: Wetting that occurs during the day

E. Secondary enuresis
1. The onset of wetting occurs after a period of established urinary continence.
2. If the child complains of dysuria, urgency, or frequency, the child would be assessed for urinary tract infections.

F. Assessment: Children older than 5 years who wet their bed or their clothes 2 times a week or more for at least 3 months

G. Interventions
1. Perform urinalysis and urine culture as prescribed to rule out infection, existing disorder, or diabetes mellitus.
2. Assist the family with identifying a treatment plan that best fits the needs of the child.
3. Limit fluid intake at night, and encourage the child to void just before going to bed.
4. Provide reward systems as appropriate for the child.
5. Incorporate behavioral conditioning techniques.
6. Desmopressin may reduce urine production at night; anticholinergics may reduce bladder contractions and increase bladder capacity.
7. Encourage follow-up to determine the effectiveness of the treatment.

VII. Cryptorchidism

A. Description: Cryptorchidism is a condition in which one or both testes fail to descend through the inguinal canal into the scrotal sac.

B. Assessment: Testes are not palpable or easily guided into the scrotum.

C. Interventions
1. Monitor during the first 6 months of life to determine whether spontaneous descent occurs.
2. Surgical correction is commonly done at 6 months of age and before 12 months, depending on the pediatric surgeon's preference.
3. Monitor for bleeding and infection postoperatively.
4. Instruct parents in postoperative home care measures, including preventing infection, pain control, and activity restrictions.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

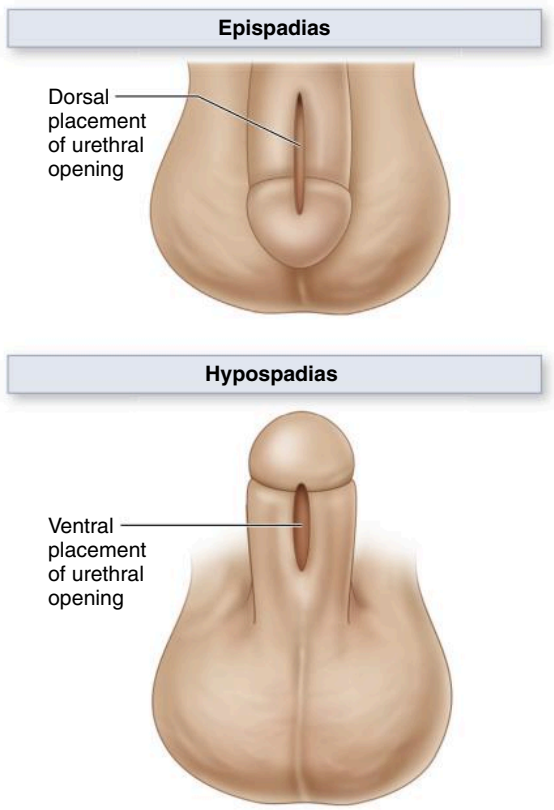

FIG. 38.2 Epispadias and hypospadias are genital anomalies in which the urethral opening is above or below its normal location on the glans of the penis.

5. Provide an opportunity for parental counseling if the parents are concerned about the future fertility of the child.

VIII. Epispadias and Hypospadias (Fig. 38.2)

A. Description
1. Epispadias and hypospadias are congenital defects involving abnormal placement of the urethral orifice of the penis.
2. These anatomical defects can lead to the easy entry of bacteria into the urine.

B. Assessment
1. Epispadias: The urethral orifice is located on the dorsal surface of the penis; the condition often occurs with exstrophy of the bladder.
2. Hypospadias: Urethral orifice is located below the glans penis along the ventral surface.

C. Surgical interventions: Surgery is done before the age of toilet training, between 6 and 12 months of age, depending on the pediatric surgeon's preference.

Circumcision may not be performed on a newborn with epispadias or hypospadias. Although there are other surgical techniques used to repair these defects, the pediatric surgeon may prefer using the foreskin for surgical reconstruction.

D. Postoperative interventions
1. The child has a pressure dressing and may have some type of urinary diversion or a urinary stent (used to maintain patency of the urethral opening) while the meatus is healing.
2. Monitor vital signs.
3. Encourage fluid intake to maintain adequate urine output and maintain patency of the stent if a stent was placed.
4. Monitor intake and output and the urine for cloudiness or a foul odor.
5. Notify the pediatric surgeon if there is no urinary output for 1 hour, because this may indicate kinks in the urinary diversion or stent or obstruction by sediment.
6. Provide pain medication or medication to relieve bladder spasms (anticholinergic) as prescribed.
7. Administer antibiotics as prescribed.
8. Instruct parents in the care of the child who has a urinary diversion or stent.
9. Instruct parents to avoid giving the child a tub bath until the stent, if present, is removed.
10. Instruct parents about fluid intake, medication administration, signs and symptoms of infection, and the need for follow-up for dressing removal after surgery as prescribed.

IX. Bladder Exstrophy

A. Description
1. Bladder exstrophy is a congenital anomaly characterized by extrusion of the urinary bladder to the outside of the body through a defect in the lower abdominal wall.
2. The cause is unknown; it is possibly a combination of genetic and environmental risk factors during pregnancy.
3. The condition can include specific defects of the abdominal wall, bladder, genitals, pelvic bones, rectum, and anus.
4. Children with bladder exstrophy will also experience vesicoureteral reflux, in which urine flows back up into the ureters to the kidneys; epispadias is also noted.
5. These defects are treated through surgical procedures that repair the affected organs, muscles, and bones.
6. Initial surgery for closure of the abdominal defect would occur within the first few days of life.
7. The goal of subsequent surgeries is to reconstruct the bladder and genitalia and enable the child to achieve urinary continence.

B. Assessment
1. Exposed bladder mucosa and epispadias (urethral orifice on dorsal surface of penis)
2. Defects of the abdominal wall
3. Vesicoureteral reflux

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Defects of the rectum and anus

C. Interventions
1. Monitor urinary output.
2. Monitor for signs of urinary tract or wound infection.
3. Maintain the integrity of the exposed bladder mucosa.
4. Prevent the bladder tissue from drying, while allowing the drainage of urine, until surgical closure is performed. Immediately after birth, as prescribed, the exposed bladder is covered with a sterile, nonadherent dressing to protect it until closure can be performed.
5. Monitor laboratory values and urinalysis to assess renal function.
6. Administer antibiotics as prescribed.
7. Provide emotional support to the parents, and encourage verbalization of their fears and concerns.

Applying petroleum jelly to the bladder mucosa is avoided because it tends to dry out, adhere to the bladder mucosa, and damage the delicate tissues when the dressing is removed.

X. Sexually Transmitted Infections (STIs)

A. Screening for certain STIs needs to be completed for certain children and adolescents. See Centers for Disease Control and Infection (2021), *Sexually transmitted infections treatment guidelines, 2021*, at https://www.cdc.gov/mmwr/volumes/70/rr/rr7004a1.htm

B. Refer to Chapter 23 for more detailed information on STIs.

PRACTICE QUESTIONS

1. The nurse reviews the record of a child who is suspected to have glomerulonephritis. Which statement that relates to this diagnosis would the nurse expect to hear from the child's parents?
   1. "The pediatrician said the kidneys are working well."
   2. "I noticed the urine was the color of cola lately."
   3. "I'm so glad they didn't find any protein in the urine."
   4. "The nurse who admitted my child said the blood pressure was low."

2. The nurse performing an admission assessment on a 2-year-old child who has been diagnosed with nephrotic syndrome notes that which **most** common characteristic is associated with this syndrome?
   1. Hypertension
   2. Generalized edema
   3. Increased urinary output
   4. Frank, bright red blood in the urine

3. The nurse is planning care for a child with hemolytic-uremic syndrome who has been anuric and will be receiving peritoneal dialysis treatment. The nurse would plan to implement which measure?
   1. Restrict fluids as prescribed.
   2. Care for the arteriovenous fistula.
   3. Encourage foods high in potassium.
   4. Administer analgesics as prescribed.

4. A 7-year-old child is seen in a clinic, and the pediatrician documents a diagnosis of nighttime (nocturnal) enuresis. The nurse would plan to provide which information to the parents?
   1. Nighttime (nocturnal) enuresis does not respond to treatment.
   2. Nighttime (nocturnal) enuresis is caused by a psychiatric problem.
   3. Nighttime (nocturnal) enuresis requires surgical intervention to improve the problem.
   4. Nighttime (nocturnal) enuresis is usually outgrown without therapeutic intervention.

5. The nurse has provided discharge instructions to the parents of a 2-year-old child who underwent an orchiopexy to correct cryptorchidism. Which statement by the parents indicates a **need for further instruction**?
   1. "I'll check my child's temperature."
   2. "I'll give medication so that my child will be comfortable."
   3. "I'll check my child's voiding to be sure there's no problem."
   4. "I'll let my child decide when to return to play activities."

6. The nurse is reviewing a treatment plan with the parents of a newborn with hypospadias. Which statement by the parents indicates their understanding of the plan?
   1. "I need to be cautious when straddling my infant on a hip."
   2. "Vital signs need to be taken daily to check for bladder infection."
   3. "Catheterization will be necessary when my infant does not void."
   4. "Circumcision has been delayed to save tissue for surgical repair."

7. The nurse is caring for an infant with a diagnosis of bladder exstrophy. To protect the exposed bladder tissue, the nurse would plan which intervention?
   1. Cover the bladder with petroleum jelly gauze.
   2. Cover the bladder with a nonadhering plastic wrap.
   3. Apply sterile distilled water dressings over the bladder mucosa.
   4. Keep the bladder tissue dry by covering it with dry sterile gauze.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. Which question would the nurse ask the parents of a child suspected of having glomerulonephritis?
   1. "Did your child fall off a bike onto the handlebars?"
   2. "Has the child had persistent nausea and vomiting?"
   3. "Has the child been itching or had a rash anytime in the last week?"
   4. "Has the child had a sore throat or a throat infection in the last few weeks?"

9. The nurse collects a urine specimen preoperatively from a child with epispadias who is scheduled for surgical repair. When analyzing the results of the urinalysis, which would the nurse **most likely** expect to note?
   1. Hematuria
   2. Proteinuria
   3. Bacteriuria
   4. Glucosuria

10. The nurse is performing an assessment on a child admitted to the hospital with a probable diagnosis of nephrotic syndrome. Which assessment findings would the nurse expect to observe? **Select all that apply.**
   - ❑ 1. Pallor
   - ❑ 2. Edema
   - ❑ 3. Anorexia
   - ❑ 4. Proteinuria
   - ❑ 5. Weight loss
   - ❑ 6. Decreased serum lipids

ANSWERS

1. *Answer:* 2

Rationale: Glomerulonephritis refers to a group of kidney disorders characterized by inflammatory injury in the glomerulus. Gross hematuria, resulting in dark, smoky, cola-colored or brown-colored urine, is a classic symptom of glomerulonephritis. Blood urea nitrogen levels and serum creatinine levels may be elevated, indicating that kidney function is compromised. A mild to moderate elevation in protein in the urine is associated with glomerulonephritis. Hypertension is also common because of fluid volume overload secondary to the kidneys not working properly.

Test-Taking Strategy: Focus on the **subject,** the manifestations of glomerulonephritis. Eliminate options 3 and 4 first, because hypertension from fluid volume overload and proteinuria are most likely to occur in this kidney disorder. Recalling that this is a renal disorder and that blood urea nitrogen levels and serum creatinine levels increase in these type of disorders will assist in directing you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp.792-793.

2. *Answer:* 2

Rationale: Nephrotic syndrome is defined as massive proteinuria, hypoalbuminemia, hyperlipemia, and edema. Other manifestations include weight gain; periorbital and facial edema that is most prominent in the morning; leg, ankle, labial, or scrotal edema; decreased urine output and urine that is dark and frothy; abdominal swelling; and blood pressure that is normal or slightly decreased.

Test-Taking Strategy: Note the **strategic word,** *most.* Recall the pathophysiology associated with nephrotic syndrome. Associate edema with nephrotic syndrome. This will help you answer questions similar to this one.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 796.

3. *Answer:* 1

Rationale: Hemolytic-uremic syndrome is thought to be associated with bacterial toxins, chemicals, and viruses that result in acute kidney injury in children. Clinical manifestations of the disease include acquired hemolytic anemia, thrombocytopenia, renal injury, and central nervous system symptoms. A child with hemolytic-uremic syndrome undergoing peritoneal dialysis because of anuria would be on fluid restriction. Pain is not associated with hemolytic-uremic syndrome, and potassium would be restricted, not encouraged, if the child is anuric. Peritoneal dialysis does not require an arteriovenous fistula (only hemodialysis).

Test-Taking Strategy: Note the **subject,** anuria. Focus on the child's diagnosis, and recall knowledge about the care of a client with acute kidney injury. Also focus on the **data in the question.** Noting the word *peritoneal* will assist in eliminating option 2. From the remaining options, remember that because the child is anuric, fluids will be restricted.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 800-801.

4. *Answer:* 4

Rationale: Nighttime (nocturnal) enuresis occurs in a child who has never been dry at night for extended periods. The condition is common in children, and most children eventually outgrow bed-wetting without therapeutic intervention. The child is unable to sense a full bladder and does not

Telegram & Insta: NCLEX_RN_Edu

awaken to void. The child may have delayed maturation of the central nervous system. The condition is not caused by a psychiatric problem.
Test-Taking Strategy: Focus on the **subject,** the characteristics of nighttime (nocturnal) enuresis. Recall that the word *enuresis* refers to urinating, and the word *nocturnal* refers to nighttime. Use knowledge about the disorder and recall that most children outgrow bed-wetting.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 505.

5. *Answer:* 4
Rationale: Cryptorchidism is a condition in which one or both testes fail to descend through the inguinal canal into the scrotal sac. Surgical correction may be necessary. All vigorous activities need to be restricted for 2 weeks after surgery to promote healing and prevent injury. This prevents dislodging of the suture, which is internal. Normally, 2-year-olds want to be active; allowing the child to decide when to return to play activities may prevent healing and cause injury. The parents would be taught to monitor the temperature, provide analgesics as needed, and monitor the urine output.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Option 1 is an important action to recognize signs of infection. Option 2 is appropriate to keep pain to a minimum. Option 3 monitors voiding pattern, which is also important after this type of surgery.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 817.

6. *Answer:* 4
Rationale: Hypospadias is a congenital defect involving abnormal placement of the urethral orifice of the penis. In hypospadias, the urethral orifice is located below the glans penis along the ventral surface. The infant would not be circumcised, because the dorsal foreskin tissue will be used for surgical repair of the hypospadias. Options 1, 2, and 3 are unrelated to this disorder.
Test-Taking Strategy: Focus on the **subject,** treatment for hypospadias. Note the words *indicates their understanding*. Recalling that hypospadias is a congenital defect involving abnormal placement of the urethral orifice of the penis will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 817.

7. *Answer:* 2
Rationale: In bladder exstrophy, the bladder is exposed and external to the body. In this disorder, one must take care to protect the exposed bladder tissue from drying, while allowing the drainage of urine. This is accomplished best by covering the bladder with a nonadhering plastic wrap. The use of petroleum jelly gauze needs to be avoided, because this type of dressing can dry out, adhere to the mucosa, and damage the delicate tissue when removed. Dry sterile dressings and dressings soaked in solutions (that can dry out) also damage the mucosa when removed.
Test-Taking Strategy: Focus on the **subject,** treatment for bladder exstrophy, and visualize this disorder. Noting the word *nonadhering* in the correct option will direct you to select this one.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 819.

8. *Answer:* 4
Rationale: Glomerulonephritis refers to a group of kidney disorders characterized by inflammatory injury in the glomerulus. Group A beta-hemolytic streptococcal infection is a cause of glomerulonephritis. Often, a child becomes ill with streptococcal infection of the upper respiratory tract and then develops symptoms of acute poststreptococcal glomerulonephritis after an interval of 1 to 2 weeks. The assessment data in options 1, 2, and 3 are unrelated to a diagnosis of glomerulonephritis.
Test-Taking Strategy: Note the **subject,** a question that will elicit information specific to the diagnosis of glomerulonephritis. Option 1 relates to a kidney injury, not an infectious process. From the remaining options, recalling that a streptococcal infection 1 to 2 weeks before the development of glomerulonephritis is the classic assessment finding will assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 791-793.

9. *Answer:* 3
Rationale: Epispadias is a congenital defect involving abnormal placement of the urethral orifice of the penis. The urethral opening is located anywhere on the dorsum of the penis. This anatomical characteristic facilitates entry of bacteria into the urine. Options 1, 2, and 4 are not characteristically noted in this condition.
Test-Taking Strategy: Note the **strategic words,** *most likely.* Visualize the anatomical characteristics of epispadias to answer the question. Options 1, 2, and 4 do not relate to the potential for infection, which can be associated with epispadias.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 785, 818-819.

10. *Answer:* 1, 2, 3, 4
Rationale: Nephrotic syndrome is a kidney disorder characterized by massive proteinuria, hypoalbuminemia, edema, elevated serum lipids, anorexia, and pallor. The child gains weight.
Test-Taking Strategy: Focus on the **subject,** the characteristics of nephrotic syndrome. Thinking about the pathophysiology associated with this disorder and recalling the assessment findings for nephrotic syndrome will direct you to the correct options.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 797.

CHAPTER 39

Neurological and Cognitive Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

Telegram & Insta: NCLEX_RN_Edu

PRIORITY CONCEPTS Intracranial Regulation; Safety

I. Cerebral Palsy

A. Description

1. Disorder characterized by impaired movement, posture, and/or muscle tone, resulting from an abnormality in the extrapyramidal or pyramidal motor system
2. The most common clinical type is spastic cerebral palsy, which represents an upper motor neuron type of muscle weakness.
3. Less common types of cerebral palsy are athetoid, ataxic, and mixed.

B. Assessment

1. Extreme irritability and crying
2. Feeding difficulties
3. Abnormal motor performance
4. Alterations of muscle tone; stiff and rigid arms or legs
5. Delayed developmental milestones
6. Persistence of primitive infantile reflexes (Moro, tonic neck) after 6 months (most primitive reflexes disappear by 3 to 4 months of age)
7. Abnormal posturing, such as opisthotonos (exaggerated arching of the back) (Fig. 39.1)
8. Seizures may occur.

C. Interventions

1. The goal of management is to recognize the disorder early and implement interventions to maximize the child's abilities.
2. An interprofessional team approach is implemented to meet the many needs of the child.
3. Therapeutic management includes physical therapy, occupational therapy, speech therapy, education, and recreation.
4. Assess the child's developmental level and intelligence.
5. Encourage early intervention and participation in school programs.
6. Prepare for using mobilizing devices to help prevent or reduce deformities.
7. Encourage communication and interaction that correspond with the child's **developmental age** level, rather than **chronological age** level.
8. Provide a safe environment by removing sharp objects, using a protective helmet if the child falls frequently, and implementing seizure precautions if necessary.
9. Provide safe, appropriate toys for the child's age and developmental level.
10. Position the child upright after meals.
11. Medications may be prescribed to relieve muscle spasms, which cause intense pain; antiseizure medications may also be prescribed.
12. Provide the parents with information about the disorder and the treatment plan; encourage support groups for parents.

II. Head Injury

A. Description

1. Head injury is the pathological result of any mechanical force to the skull, scalp, meninges, or brain (Fig. 39.2).
   - **a.** Open head injury occurs when there is a fracture of the skull or penetration of the skull by an object.
   - **b.** Closed head injury is the result of blunt trauma (this is more serious than an open head injury because of the chance of increased intracranial pressure [ICP] in a "closed" vault); this type of injury can also be caused by shaken baby syndrome.
2. Manifestations depend on the type of injury and the subsequent amount of increased ICP.

Telegram & Insta: NCLEX_RN_Edu

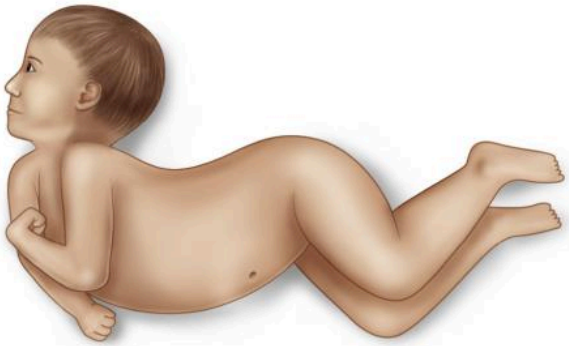

FIG. 39.1 Abnormal posturing: opisthotonos.

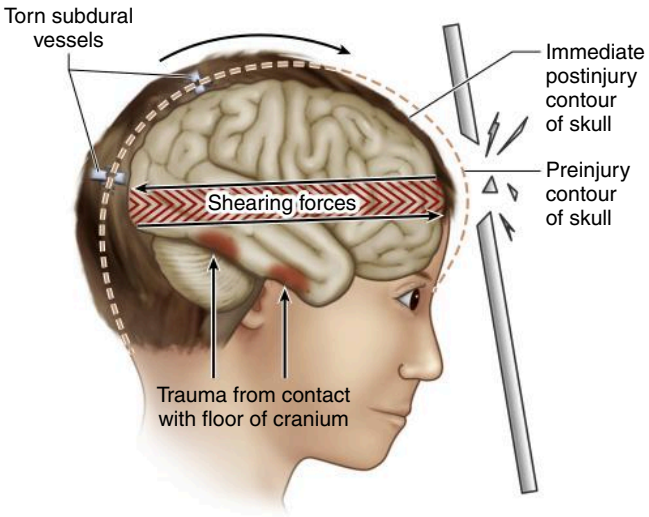

Torn subdural vessels
Immediate postinjury contour of skull
Preinjury contour of skull
Shearing forces
Trauma from contact with floor of cranium

FIG. 39.2 Mechanical distortion of cranium during closed head injury.

B. Assessment: Increased ICP

The child's level of consciousness provides the earliest indication of an improvement or deterioration of the neurological condition.

1. Early signs
   - **a.** Slight change in vital signs
   - **b.** Slight change in level of consciousness
   - **c.** Infant: Irritability, high-pitched cry, bulging fontanel, increased head circumference, dilated scalp veins, Macewen's sign (cracked-pot sound on percussion of the head), setting sun sign (sclera visible above the iris)
   - **d.** Child: Headache, nausea, vomiting, visual disturbances (diplopia), seizures
2. Late signs
   - **a.** Significant decrease in level of consciousness
   - **b.** Bradycardia
   - **c.** Decreased motor and sensory responses
   - **d.** Alteration in pupil size and reactivity
   - **e.** Decorticate (flexion) posturing: Adduction of the arms at the shoulders; arms are flexed on the chest with the wrists flexed and the hands fisted, and the lower extremities are extended and adducted; seen with severe dysfunction of cerebral cortex (Fig. 39.3)
   - **f.** Decerebrate (extension) posturing: Rigid extension and pronation of the arms and the legs; sign of dysfunction at the level of the midbrain (see Fig. 39.3)
   - **g.** Cheyne-Stokes respirations
   - **h.** Coma

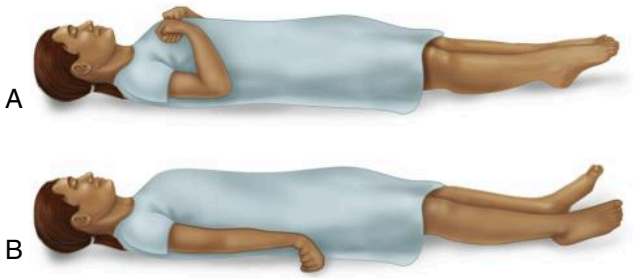

FIG. 39.3 **A,** Decorticate (flexion) posturing. **B,** Decerebrate (extension) posturing.

Immobilize the neck and spine after a head injury if a cervical or other spinal injury is suspected. When a spinal cord injury is ruled out, elevate the head of the bed 15 to 30 degrees, if not contraindicated and as prescribed, to facilitate venous drainage.

C. Interventions

1. Monitor the airway; administer oxygen as prescribed.
2. Assess injuries. (See Chapter 59 for information on spinal cord injuries.)
3. Position the client so that the head is maintained midline to avoid jugular vein compression, which can increase ICP.
4. Monitor vital signs and neurological function (assess level of consciousness closely).
5. Notify the primary health care provider (PHCP) if signs of increased ICP occur.
6. Keep stimuli to a minimum; attempt to minimize crying in an infant.
7. Withhold sedating medications during the acute phase of the injury so that changes in levels of consciousness can be assessed.
8. Initiate seizure precautions (see Clinical Judgment: Generate Solutions Box).
9. Monitor for decreased responsiveness to pain (a significant sign of altered level of consciousness).
10. Maintain NPO (nothing by mouth) status or provide clear liquids, if prescribed, until it is determined that vomiting will not occur.
11. Monitor prescribed intravenous fluids carefully to avoid increasing any cerebral edema and to minimize the possibility of overhydration.
12. Monitor for a fluid or electrolyte alteration (could indicate injury to the hypothalamus or posterior pituitary).

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: GENERATE SOLUTIONS

The nurse is caring for a 10-year-old child who sustained a blunt head injury when accidentally hit with a baseball bat. The child exhibits a significant decrease in level of consciousness, bradycardia, and decorticate posturing. The child is at risk for seizures, and the nurse creates a plan of care to initiate seizure precautions; the plan includes the following actions:

- Have suction equipment and oxygen available.
- Raise the side rails on the bed.
- Pad the side rails and other hard objects.
- Clear the area of any hazards or hard objects.
- Place a waterproof mattress or pad on the bed.
- Alert caregivers to the need for seizure precautions or any other special precautions.

13. Assess wounds and dressings for the presence of drainage, and monitor for nose or ear drainage, which could indicate leakage of cerebrospinal fluid (CSF).
14. Administer tepid sponge baths or place the child on a hypothermia blanket as prescribed if hyperthermia occurs.
15. Avoid suctioning through the nares because of the possibility of the catheter entering the brain through a fracture, which places the child at high risk for a secondary infection.
16. As prescribed, administer acetaminophen for headache, anticonvulsants for seizures, and antibiotics if a laceration is present; prepare to administer prophylactic tetanus toxoid.
17. A corticosteroid or osmotic diuretic may be prescribed to reduce cerebral edema.
18. Monitor for signs of brainstem involvement (Box 39.1).
19. Monitor for signs of epidural hematoma. Asymmetrical pupils (one dilated, nonreactive pupil) may indicate a neurosurgical emergency that requires evacuation of the hematoma.

⚠ Drainage from the nose or ear needs to be tested for the presence of glucose. Drainage that is positive for glucose (as tested with reagent strips) indicates leakage of CSF. The PHCP must be notified immediately if the drainage tests positive for glucose.

III. Hydrocephalus

A. Description
1. An imbalance of CSF absorption or production that is either the result of congenital complication or an acquired condition such as tumors, hemorrhage, infections, or trauma
2. Results in head enlargement and increased ICP

BOX 39.1 Signs of Brainstem Involvement

- Deep, rapid, or intermittent and gasping respirations
- Wide fluctuations or noticeable slowing of pulse
- Widening pulse pressure or extreme fluctuations in blood pressure
- Sluggish, dilated, or unequal pupils

Notify the PHCP immediately if these signs develop!

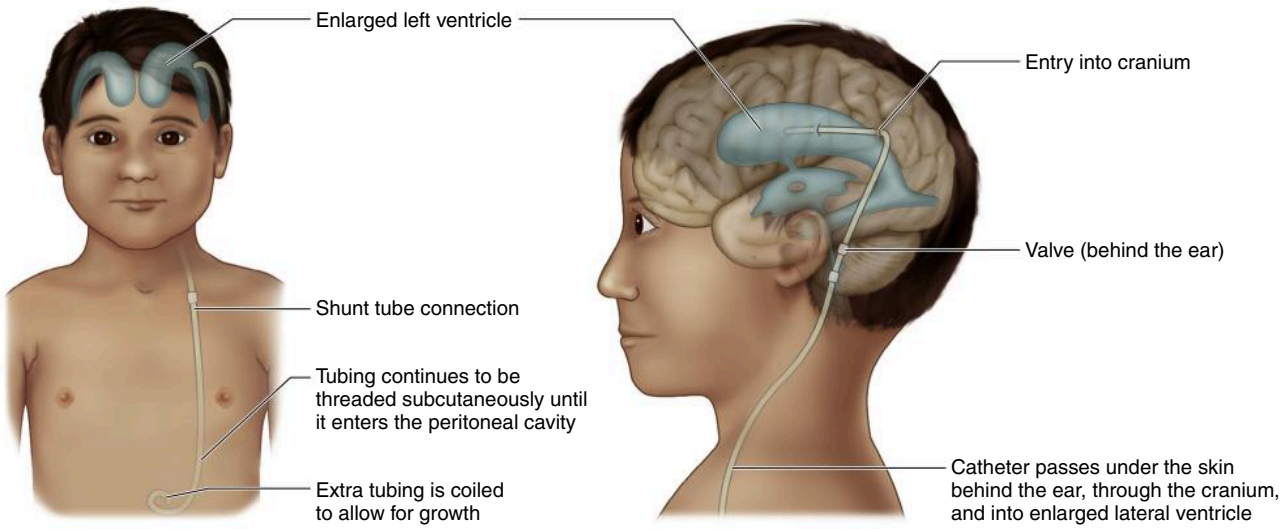
B. Types
1. Communicating: Hydrocephalus occurs as a result of impaired absorption within the subarachnoid space, obliteration of the subarachnoid cisterns, or malfunction of the arachnoid villi.
2. Noncommunicating (obstructive): Hydrocephalus occurs as a result of excess cerebrospinal fluid (CSF) due to structural blockage within the ventricular system.

C. Assessment
1. Infant
   - **a.** Increased head circumference
   - **b.** Thin, widely separated bones of the head that produce a cracked-pot sound (Macewen's sign) on percussion
   - **c.** Anterior fontanel tense, bulging, and nonpulsating; sutures will separate prior to fontanel bulging.
   - **d.** Pupils become sluggish and have an unequal response to light
   - **e.** Increased irritability
   - **f.** Changes in LOC
   - **g.** Lower extremity spasticity
   - **h.** Poor feeding
   - **i.** Dilated scalp veins
   - **j.** Frontal bossing
   - **k.** "Setting sun" eyes
2. Child
   - **a.** Signs and symptoms seen in early to late childhood are caused by the increase in intracranial pressure and are dependent upon the location of the focal lesion.
   - **b.** Behavioral changes, such as irritability and lethargy
   - **c.** Headache on awakening
   - **d.** Nausea and vomiting
   - **e.** Ataxia
   - **f.** Strabismus
   - **g.** Papilledema
3. Late signs: High, shrill cry and seizures

D. Surgical interventions
1. The goal of surgical treatment is to prevent further CSF accumulation by bypassing the blockage and draining the fluid from the ventricles to a location where it may be reabsorbed.
2. In a ventriculoperitoneal **shunt**, the CSF drains into the peritoneal cavity from the lateral ventricle (Fig. 39.4).

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu



Enlarged left ventricle
Entry into cranium
Valve (behind the ear)
Shunt tube connection
Tubing continues to be threaded subcutaneously until it enters the peritoneal cavity
Extra tubing is coiled to allow for growth
Catheter passes under the skin behind the ear, through the cranium, and into enlarged lateral ventricle

FIG. 39.4 Ventriculoperitoneal shunt.

3. In a ventriculoatrial shunt, CSF drains into the right atrium of the heart from the lateral ventricle, bypassing the obstruction (used in older children and in children with pathological conditions of the abdomen).
4. Shunt revision may be necessary as the child grows.
5. An alternative to shunt placement is endoscopic third ventriculostomy, in which a small opening in the floor of the third ventricle is made that allows CSF to bypass the fourth ventricle and return to the circulation to be absorbed; this treatment may not be appropriate for some types of hydrocephalus.

E. Preoperative interventions
1. Monitor intake and output; give small, frequent feedings as tolerated until preoperative NPO status is prescribed.
2. Reposition the head frequently and use special devices such as an egg crate mattress under the head to prevent pressure sores.
3. Prepare the child and family for diagnostic procedures and surgery.

F. Postoperative interventions
1. Monitor vital signs and neurological signs.
2. Position the child on the unoperated side to prevent pressure on the shunt valve.
3. Keep the child flat if prescribed to avoid rapid reduction of intracranial fluid.
4. Observe for increased ICP; if increased ICP occurs, elevate the head of the bed to 15 to 30 degrees to enhance gravity flow through the shunt.
5. Measure head circumference.
6. Monitor for signs of infection, and assess dressings for drainage.
7. Monitor intake and output.
8. Provide comfort measures and administer medications as prescribed.
9. Instruct parents on how to recognize shunt infection or malfunction.
10. In an infant, irritability, lethargy, feeding poorly, and a high, shrill cry may indicate shunt malfunction or infection.
11. In a toddler, headache and a lack of appetite are the earliest common signs of shunt malfunction.
12. In older children, an indicator of shunt malfunction is an alteration in the child's level of consciousness.
13. Monitor for shunt presence behind the ear.

A high, shrill cry in an infant can be a sign of increased ICP.

IV. Meningitis

A. Description
1. Meningitis is an infectious process of the central nervous system caused by bacteria or viruses that may be acquired as a primary disease or as a result of complications of neurosurgery, trauma, infection of the sinuses or ears, or systemic infections.
2. Diagnosis of bacterial meningitis is made by testing CSF obtained by lumbar puncture; the fluid is cloudy with increased pressure, increased white blood cell count, elevated protein, and decreased glucose levels.
3. Bacterial meningitis can be caused by various organisms, most commonly *Haemophilus influenzae* type b, *Streptococcus pneumoniae*, or *Neisseria meningitidis;* meningococcal meningitis occurs in epidemic form and can be transmitted by droplets from nasopharyngeal secretions.
4. Viral meningitis is associated with viruses such as mumps, paramyxovirus, herpesvirus, and enterovirus.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Assessment

1. Signs and symptoms vary, depending on the type, the age of the child, and the duration of the preceding illness.
2. Fever, chills, headache
3. Vomiting, diarrhea
4. Poor feeding or anorexia
5. Nuchal rigidity
6. High shrill cry
7. Altered level of consciousness, such as lethargy or irritability
8. Bulging anterior fontanel in an infant
9. Positive Kernig's sign (inability to extend the leg when the thigh is flexed anteriorly at the hip) and Brudzinski's sign (neck flexion causes adduction and flexion movements of the lower extremities) in children and adolescents
10. Muscle or joint pain (meningococcal infection and *H. influenzae* infection)
11. Petechial or purpuric rashes (meningococcal infection)
12. Ear that chronically drains (pneumococcal meningitis)

C. Interventions

1. Provide respiratory isolation precautions and maintain the precautions for at least 24 hours after antibiotics are initiated.
2. Administer antibiotics and antipyretics as prescribed (administer antibiotics as soon as they are prescribed after lumbar puncture); antiseizure medications may also be prescribed.
3. Perform neurological assessment and monitor for seizures; assess for the complication of inappropriate antidiuretic hormone secretion, causing fluid retention (cerebral edema) and dilutional hyponatremia.
4. Assess for changes in level of consciousness and irritability.
5. Monitor for a purpuric or petechial rash and for signs of thromboemboli.
6. Assess nutritional status; monitor intake and output.
7. Monitor for hearing loss.
8. Determine close contacts of the child with meningitis, because the contacts need prophylactic treatment.
9. Pneumococcal conjugate **vaccine** is recommended for all children beginning at age 2 months to protect against meningitis; streptococcal pneumococci can cause many bacterial infections, including meningitis (see Chapter 19 for information on vaccines).

V. Submersion Injury

A. Description

1. Survival of at least 24 hours after submersion in a fluid medium
2. Hypoxia/asphyxiation is the primary problem because it results in extensive cell damage; cerebral cells sustain irreversible damage after 4 to 6 minutes of submersion.
3. Additional problems include aspiration and hypothermia.
4. Outcome is predicted on the basis of the length of submersion in non-icy water; outcome may be good if submersion was for less than 5 minutes and the child exhibits neurological responsiveness, reactive pupils, and a normal cardiac rhythm.
5. A child who was submerged for more than 10 minutes and does not respond to cardiopulmonary life support measures within 25 minutes has an extremely poor prognosis (severe neurological impairment or death).

B. Interventions

1. Provide ventilatory and circulatory support; if the child has had a severe cerebral insult, endotracheal intubation and mechanical ventilation may be required.
2. Monitor respiratory status, because respiratory compromise and cerebral edema may occur 24 hours after the incident.
3. Monitor for aspiration pneumonia.
4. Monitor neurological status closely; if spontaneous purposeful movement and normal brainstem function are not apparent 24 hours after the event, the child most likely has sustained severe neurological deficits.
5. Teach parents to provide adequate supervision of infants and small children around water to prevent accidents.

VI. Reye's Syndrome

A. Description

1. Reye's syndrome is an acute encephalopathy that follows a viral illness and is characterized pathologically by cerebral edema and fatty changes in the liver, fluid and electrolyte imbalance, acid-base imbalance, and coagulopathies; diagnosis is made by laboratory studies and liver biopsy.
2. The exact cause is unclear; it most commonly follows a viral illness such as influenza or varicella.
3. Administration of aspirin or aspirin-containing products is not recommended for children with a febrile illness or children with varicella or influenza or other viral illnesses because of its association with Reye's syndrome.
4. Acetaminophen and ibuprofen are considered the medications of choice.
5. Early diagnosis and aggressive treatment are important; the goal of treatment is to maintain effective cerebral perfusion and to control increasing ICP.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Assessment
1. History of systemic viral illness 4 to 7 days before the onset of symptoms
2. Fever
3. Nausea and vomiting
4. Signs of altered hepatic function such as lethargy
5. Progressive neurological deterioration
6. Increased blood ammonia levels

C. Interventions
1. Provide rest and decrease stimulation in the environment.
2. Assess neurological status.
3. Monitor for altered level of consciousness and signs of increased ICP.
4. Monitor for signs of altered hepatic function and results of liver function studies.
5. Monitor intake and output.
6. Monitor for signs of bleeding and signs of impaired coagulation, such as a prolonged bleeding time.

VII. Seizure Disorders

A. Description (see Chapter 59 for additional information on seizures)
1. Excessive and unorganized neuronal discharges in the brain that activate associated motor and sensory organs
2. Classified as generalized, partial, or unclassified, depending on the area of the brain involved
3. Types of generalized seizures include tonic-clonic, absence, myoclonic, and atonic.
4. Partial seizures arise from a specific area in the brain and cause limited symptoms; types include simple partial and complex partial.

B. Assessment
1. Obtain information from the parents about the time of onset, precipitating events, and behavior before and after the seizure.
2. Determine the child's history related to seizures.
3. Ask the child about the presence of an aura (a warning sign of impending seizure).
4. Monitor for apnea and cyanosis.
5. Postseizure (postictal state): The child is disoriented and sleepy.

C. Seizure precautions (see Clinical Judgment: Generate Solutions Box)

D. Interventions (Box 39.2)

E. Home care instructions
1. Wear or carry medical identification.
2. Take precautions during potentially hazardous activities.
3. Swim with a companion.
4. Use a protective helmet and padding when engaged in bicycle riding, skateboarding, and in-line skating.
5. Take medications as scheduled to prevent seizures.

F. Antiseizure medications (see Chapter 60 for information on medications)

BOX 39.2 Interventions for Seizures

- Ensure airway patency.
- Have suction equipment and oxygen available.
- Time the seizure episode.
- If the child is standing or sitting, ease the child down to the floor and place the child in a side-lying position.
- Place a pillow or folded blanket under the child's head; if no bedding is available, place your own hands under the child's head or place the child's head in your own lap.
- Loosen restrictive clothing.
- Remove eyeglasses from the child if present.
- Clear the area of any hazards or hard objects.
- Allow the seizure to proceed and end without interference.
- If vomiting occurs, turn the child to one side as a unit.
- Do not restrain the child, place anything in the child's mouth, or give any food or liquids to the child.
- Prepare to administer medications as prescribed.
- Remain with the child until the child recovers fully.
- Observe for incontinence, which may have occurred during the seizure.
- Document the occurrence.

! Never place anything, including an airway device, into the mouth of a child during a seizure.

VIII. Neural Tube Defects

A. Description
1. This central nervous system defect results from failure of the neural tube to close during embryonic development.
2. Folic acid is recommended during childbearing years and pregnancy to reduce the occurrence of these conditions.
3. Associated deficits include sensorimotor disturbance, dislocated hips, talipes equinovarus (clubfoot), and hydrocephalus.
4. Defect closure is performed soon after birth.

B. Types
1. Spina bifida occulta
   - **a.** Posterior vertebral arches fail to close in the lumbosacral area.
   - **b.** Spinal cord remains intact and usually is not visible.
   - **c.** Meninges are not exposed on the skin surface.
   - **d.** Neurological deficits are not usually present.
2. Closed neural tube defect
   - **a.** This type consists of a diverse group of defects; the spinal cord is marked by malformations of fat, bone, or meninges.
   - **b.** Usually there are few or no symptoms; in some situations the malformation causes incomplete paralysis with urinary and bowel dysfunction.
3. Meningocele
   - **a.** Protrusion involves meninges and a saclike cyst that contains CSF in the midline of the back, usually in the lumbosacral area.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

b. The spinal cord is not involved.
c. Neurological deficits are usually not present.

4. Myelomeningocele
a. Protrusion of the meninges, CSF, nerve roots, and a portion of the spinal cord occurs.
b. The sac (defect) is covered by a thin membrane prone to leakage or rupture.
c. Neurological deficits are evident.

C. Assessment
1. Depends on the spinal cord involvement
2. Visible spinal defect
3. Flaccid paralysis of the legs
4. Altered bladder and bowel function
5. Hip and joint deformities
6. Hydrocephalus

D. Interventions
1. Evaluate the sac and measure the lesion.
2. Perform neurological assessment.
3. Monitor for increased ICP, which might indicate developing hydrocephalus.
4. Measure head circumference; assess anterior fontanel for bulging.
5. Protect the sac; as prescribed, cover with a sterile, moist (normal saline), nonadherent dressing to maintain the moisture of the sac and contents.
6. Change the dressing covering the sac on a regular schedule or whenever it becomes soiled because of the risk of infection; diapering may be contraindicated until the defect has been repaired.
7. Use aseptic technique to prevent infection.
8. Assess the sac for redness, clear or purulent drainage, abrasions, irritation, and signs of infection.
9. Early signs of infection include elevated temperature (axillary), irritability, lethargy, and nuchal rigidity.
10. Place in a prone position to minimize tension on the sac and the risk of trauma; the head is turned to one side for feeding.
11. Assess for physical impairments such as hip and joint deformities.
12. Prepare the child and family for surgery.
13. Administer antibiotics preoperatively and postoperatively, as prescribed, to prevent infection.
14. Teach the parents and eventually the child about long-term home care.
a. Positioning, feeding, skin care, and range-of-motion exercises
b. Instituting a bladder elimination program and performing clean intermittent catheterization technique if necessary
c. Administering antispasmodics (that act on the smooth muscle of the bladder) as prescribed to increase bladder capacity and improve continence
d. Implementing a bowel program, including a high-fiber diet, increased fluids, and suppositories as needed
e. The child is at high risk for allergy to latex and rubber products because of the frequent exposure to latex during implementation of care measures.

IX. Attention-Deficit/Hyperactivity Disorder

A. Description
1. Behavioral disorder characterized by developmentally inappropriate degrees of inattention, overactivity, and impulsivity
2. Childhood problems include lowered intellectual development, some minor physical abnormalities, sleeping disturbances, behavioral or emotional disorders, and difficulty in social relationships.
3. Early diagnosis is important to prevent impaired emotional and psychological development.
4. Diagnosis is established on the basis of self-reports, parent and teacher reports, and the use of assessment tools.

B. Assessment
1. Fidgets with hands or feet or squirms in the seat
2. Easily distracted with external or internal stimuli
3. Difficulty with following through on instructions
4. Poor attention span
5. Shifts from one uncompleted activity to another
6. Talks excessively
7. Interrupts or intrudes on others
8. Engages in physically dangerous activities without considering the possible consequences

C. Interventions
1. Provide parents with information about the disorder and treatment plan; encourage support groups for parents.
2. Treatment includes behavioral therapy, medication, maintaining a consistent environment, and appropriate classroom placement.
3. Behavioral therapy focuses on preventing undesirable behavior.
4. Maintain a consistent home and classroom environment, and provide environmental and physical safety measures.
5. Promote self-esteem.
6. Stimulant medications may be prescribed; possible side effects include appetite suppression and weight loss, nervousness, tics, insomnia, and increased blood pressure.
7. Instruct the child and parents about medication administration and the need for regular follow-up.

X. Autism Spectrum Disorders

A. Description
1. Autism spectrum disorders (ASDs) are complex neurodevelopmental disorders of unknown etiology composed of qualitative alterations in social interaction and verbal impairment with

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

repetitive, restricted, and stereotypical behavioral patterns.
2. Autism spectrum disorder impairments range from mild to severe; types include autism, Asperger's syndrome, and Rett's syndrome.
3. Symptoms are usually noticed by the parents by 3 years of age.
4. The cause of the disorder is not specifically known; however, it has been linked to a wide range of antepartum, intrapartum, and newborn conditions and exposure to hazardous chemicals; genetic predisposition is also linked to the disorder.
5. The disorder is accompanied by intellectual and social behavioral deficits, and the child exhibits peculiar and bizarre characteristics with social interactions, communication, and behaviors.
6. Despite their relatively moderate to severe disability, some children with autism (known as *savants*) excel in particular areas, such as art, music, memory, mathematics, or perceptual skills such as puzzle building.
7. Diagnosis is established on the basis of symptoms and the use of several screening tools.

B. Assessment
1. Social
   a. Abnormal or lack of comfort-seeking behaviors
   b. Abnormal or lack of social play
   c. Impairment in peer relationships
   d. Lack of awareness of the existence or feelings of others
   e. Abnormal imitation of others
2. Communication
   a. Lack of, impaired, or abnormal speech, such as producing a monotone voice or echolalia
   b. Abnormal nonverbal communication (does not use gestures to communicate)
3. Behavior
   a. Lack of imaginative play
   b. Persistent preoccupation or attachment to objects; range of interests restricted
   c. Self-injurious behaviors
   d. Must maintain routine; any environmental change produces marked distress
   e. Produces repetitive body movements such as rocking or head banging

C. Interventions
1. Determine the child's routines, habits, and preferences, and maintain consistency as much as possible.
2. Determine the specific ways in which the child communicates, and use these methods.
3. Avoid placing demands on the child.
4. Implement safety precautions as necessary for self-injurious behaviors such as head banging.
5. Initiate referrals to special programs as required.
6. Provide support to parents.
7. The Modified Checklist for Autism in Toddlers—Revised (MCHAT-R) is used to screen toddlers for this disorder. For a copy of the tool, see https://www.autismspeaks.org/sites/default/files/docs/sciencedocs/m-chat/m-chat-r_f.pdf?v=1

! Ensuring a safe environment for a child with autism is a priority.

XI. Intellectual Disability

A. Description
1. In intellectual disability, a child manifests subaverage intellectual functioning along with deficits in adaptive skills.
2. Down's syndrome is a congenital condition that results in moderate to severe intellectual disabilities and has been linked to an extra group G chromosome, chromosome 21 (trisomy 21).

B. Assessment
1. Deficits in cognitive skills and level of adaptive functioning
2. Delays in fine and gross motor skills
3. Speech delays
4. Decreased spontaneous activity
5. Nonresponsiveness
6. Irritability
7. Poor eye contact during feeding

C. Interventions
1. Medical strategies are focused on correcting structural deformities and treating associated behaviors.
2. Implement community and educational services, using a multidisciplinary approach.
3. Promote care skills as much as possible.
4. Assist with communication and socialization skills.
5. Facilitate appropriate play time.
6. Initiate safety precautions as necessary.
7. Assist the family with decisions regarding care.
8. Provide information regarding support services and community agencies.

PRACTICE QUESTIONS

1. The parents of a child recently diagnosed with cerebral palsy ask the nurse about the limitations of the disorder. The nurse responds by explaining that the limitations occur as a result of which pathophysiological process?
   1. An infectious disease of the central nervous system
   2. An inflammation of the brain as a result of a viral illness
   3. A chronic disability characterized by impaired muscle movement and posture
   4. A congenital condition that results in moderate to severe intellectual disabilities

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. The nurse notes documentation that a child is exhibiting an inability to flex the leg when the thigh is flexed anteriorly at the hip. Which condition does the nurse suspect?
1. Meningitis
2. Spinal cord injury
3. Intracranial bleeding
4. Decreased cerebral blood flow

3. A 5-year-old child arrives at the emergency department, and the child's parents state that the child fell off a bunk bed. A head injury is suspected. The nurse checks the child's airway status and assesses the child for early and late signs of increased intracranial pressure (ICP). Which is a **late** sign of increased ICP?
1. Nausea
2. Irritability
3. Headache
4. Bradycardia

4. The nurse is assigned to care for an 8-year-old child with a diagnosis of a basilar skull fracture. The nurse reviews the pediatrician's prescriptions and would contact the pediatrician to question which prescription?
1. Obtain daily weight.
2. Provide clear liquid intake.
3. Nasotracheal suction as needed.
4. Maintain a patent intravenous line.

5. The nurse is reviewing the record of a child with increased intracranial pressure from a head injury and notes that the child has exhibited signs of decerebrate posturing. On assessment of the child, the nurse expects to note which characteristic of this type of posturing?
1. Flaccid paralysis of all extremities
2. Adduction of the arms at the shoulders
3. Rigid extension and pronation of the arms and legs
4. Abnormal flexion of the upper extremities and extension and adduction of the lower extremities

6. A child is diagnosed with Reye's syndrome. The nurse creates a nursing care plan for the child and would include which intervention in the plan?
1. Assessing hearing loss
2. Monitoring urine output
3. Changing body position every 2 hours
4. Providing a quiet atmosphere with dimmed lighting

7. The nurse creates a plan of care for a child at risk for tonic-clonic seizures. In the plan of care, the nurse identifies seizure precautions and documents that which item(s) needs to be placed at the child's bedside?
1. Emergency cart
2. Tracheotomy set
3. Padded tongue blade
4. Suctioning equipment and oxygen

8. A lumbar puncture is performed on a child suspected to have bacterial meningitis, and cerebrospinal fluid (CSF) is obtained for analysis. The nurse reviews the results of the CSF analysis and determines that which results would verify the diagnosis?
1. Clear CSF, decreased pressure, and elevated protein level
2. Clear CSF, elevated protein, and decreased glucose levels
3. Cloudy CSF, elevated protein, and decreased glucose levels
4. Cloudy CSF, decreased protein, and decreased glucose levels

9. The nurse is planning care for a child with acute bacterial meningitis. Based on the mode of transmission of this infection, which precautionary intervention would be included in the plan of care?
1. Maintain enteric precautions.
2. Maintain neutropenic precautions.
3. No precautions are required as long as antibiotics have been started.
4. Maintain respiratory isolation precautions for at least 24 hours after the initiation of antibiotics.

10. An infant with a diagnosis of hydrocephalus is scheduled for surgery. Which is the **priority** nursing intervention in the preoperative period?
1. Test the urine for protein.
2. Reposition the infant frequently.
3. Provide a stimulating environment.
4. Assess blood pressure every 15 minutes.

11. The nurse is creating a plan of care for a child who is at risk for seizures. Which interventions apply if the child has a seizure? **Select all that apply.**
- ❑ 1. Time the seizure.
- ❑ 2. Restrain the child.
- ❑ 3. Stay with the child.
- ❑ 4. Place the child in a prone position.
- ❑ 5. Move furniture away from the child.
- ❑ 6. Insert a padded tongue blade in the child's mouth.

ANSWERS

1. *Answer:* 3

Rationale: Cerebral palsy is a chronic disability characterized by impaired movement and posture resulting from an abnormality in the extrapyramidal or pyramidal motor system. Meningitis is an infectious process of the central nervous system. Encephalitis is an inflammation of the brain that occurs as a result of viral illness or central nervous system infection. Down's syndrome is an example of a congenital condition that results in moderate to severe intellectual disabilities.

Test-Taking Strategy: Eliminate options 1 and 2 first, noting that they are **comparable or alike.** Next, note the relationship between the words *palsy* in the question and *impaired muscle movement* in the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1302-1303.

2. *Answer:* 1

Rationale: Meningitis is an infectious process of the central nervous system caused by bacteria and viruses. The inability to extend the leg when the thigh is flexed anteriorly at the hip is a positive Kernig's sign, noted in meningitis. Kernig's sign is not seen specifically with spinal cord injury, intracranial bleeding, or decreased cerebral blood flow.

Test-Taking Strategy: Note the **data in the question** and determine what this data indicates. Recalling that these are characteristics of Kernig's sign and thinking about the conditions that elicit this sign will assist in answering correctly. Also, think about the neurological exam and physical assessment findings to answer correctly.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1135.

3. *Answer:* 4

Rationale: Head injury is the pathological result of any mechanical force to the skull, scalp, meninges, or brain. A head injury can cause bleeding in the brain and result in increased ICP. In a child, early signs include a slight change in level of consciousness, headache, nausea, vomiting, visual disturbances (diplopia), and seizures. Late signs of increased ICP include a significant decrease in level of consciousness, bradycardia, decreased motor and sensory responses, alterations in pupil size and reactivity, posturing, Cheyne-Stokes respirations, and coma.

Test-Taking Strategy: Note the age of the child and the **strategic word,** *late*. Think about the pathophysiology that occurs when pressure increases in the cranial vault to assist in answering correctly.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1111.

4. *Answer:* 3

Rationale: A basilar skull fracture is a type of head injury. Nasotracheal suctioning is contraindicated in a child with a basilar skull fracture. Because of the nature of the injury, there is a possibility that the catheter will enter the brain through the fracture, creating a high risk of secondary infection. Fluid balance is monitored closely by daily weight determination, intake and output measurement, and serum osmolality determination to detect early signs of water retention, excessive dehydration, and states of hypertonicity or hypotonicity. The child is maintained on NPO (nothing by mouth) status or restricted to clear liquids until it is determined that vomiting will not occur. An intravenous line is maintained to administer fluids or medications, if necessary.

Test-Taking Strategy: Note the words *question which prescription*. Eliminate options 1, 2, and 4 because they are **comparable or alike** in that they address the subject of fluids. Remember that nasotracheal suctioning is contraindicated in a child with a skull fracture because of the risk of infection.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1130.

5. *Answer:* 3

Rationale: Decerebrate (extension) posturing is characterized by the rigid extension and pronation of the arms and legs. Option 1 is incorrect. Options 2 and 4 describe decorticate (flexion) posturing.

Test-Taking Strategy: Focus on the **subject,** characteristics of decerebrate (*extension*) posturing. Recalling the clinical manifestations associated with decerebrate posturing will direct you to the correct option. Remember that decerebrate posturing is characterized by the rigid *extension* and pronation of the arms and legs.

Reference(s): Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p.1116.

6. *Answer:* 4

Rationale: Reye's syndrome is an acute encephalopathy that follows a viral illness and is characterized pathologically by cerebral edema and fatty changes in the liver. In Reye's syndrome, supportive care is directed toward monitoring and managing cerebral edema. Decreasing stimuli in the environment by providing a quiet environment with dimmed lighting would decrease the stress on the cerebral tissue and neuron responses. Hearing and urine output are not affected. Changing the body position every 2 hours would not affect the cerebral edema directly. The child needs to be positioned with the head elevated to decrease the progression of the cerebral edema and promote drainage of cerebrospinal fluid.

Test-Taking Strategy: Focus on the **subject,** nursing care for the child with Reye's syndrome. Think about the pathophysiology associated with Reye's syndrome. Recalling that cerebral edema is a concern for a child with Reye's syndrome will direct you to the correct option.

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 686.

7. *Answer:* 4

Rationale: A seizure results from excessive and unorganized neuronal discharges in the brain that activate associated motor and sensory organs. A type of generalized seizure is a tonic-clonic seizure. This type of seizure causes rigidity of all body

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

muscles, followed by intense jerking movements. Because increased oral secretions and apnea can occur during and after the seizure, oxygen and suctioning equipment are placed at the bedside. A tracheotomy is not performed during a seizure. No object, including a padded tongue blade, is placed into the child's mouth during a seizure. An emergency cart would not be left at the bedside but would be available in the treatment room or nearby on the nursing unit.

Test-Taking Strategy: Focus on the **subject,** seizure precautions. Note the words *needs to be placed at the child's bedside*. Eliminate option 2, knowing that a tracheotomy is not performed. Next, recalling that no object is placed into the mouth of a child experiencing a seizure assists in eliminating option 3. From the remaining options, focus on the primary concern during seizure activity. This will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1146, 1154.

8. *Answer:* 3

Rationale: Meningitis is an infectious process of the central nervous system caused by bacteria and viruses; it may be acquired as a primary disease or as a result of complications of neurosurgery, trauma, infection of the sinus or ears, or systemic infections. Meningitis is diagnosed by testing CSF obtained by lumbar puncture. In the case of bacterial meningitis, findings usually include an elevated pressure; turbid or cloudy CSF; and elevated leukocyte, elevated protein, and decreased glucose levels.

Test-Taking Strategy: Use knowledge regarding the diagnostic findings in meningitis. Eliminate options 1 and 2 first because they are **comparable or alike**; recall that clear CSF is not likely to be found in an infectious process such as meningitis. From this point, recall that an elevated protein level indicates a possible diagnosis of meningitis to direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1136.

9. *Answer:* 4

Rationale: Meningitis is an infectious process of the central nervous system caused by bacteria and viruses; it may be acquired as a primary disease or as a result of complications of neurosurgery, trauma, infection of the sinus or ears, or systemic infections. A major priority of nursing care for a child suspected to have meningitis is to administer the prescribed antibiotic as soon as a culture is obtained. The child also is placed on respiratory isolation precautions for at least 24 hours while culture results are obtained and the antibiotic is having an effect. Enteric precautions and neutropenic precautions are not associated with the mode of transmission of meningitis. Enteric precautions are instituted when the mode of transmission is through the gastrointestinal tract. Neutropenic precautions are instituted when a child has a low neutrophil count.

Test-Taking Strategy: Focus on the **subject,** the mode of transmission of meningitis. Eliminate options 1 and 2 first because they are **comparable or alike,** and are unrelated to the mode of transmission. Recalling that it takes about 24 hours for antibiotics to reach a therapeutic blood level will assist in directing you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1137.

10. *Answer:* 2

Rationale: Hydrocephalus occurs as a result of an imbalance of cerebrospinal fluid absorption or production that is caused by malformations, tumors, hemorrhage, infections, or trauma. It results in head enlargement and increased intracranial pressure (ICP). In infants with hydrocephalus, the head grows at an abnormal rate, and if the infant is not repositioned frequently, pressure ulcers can occur on the back and side of the head. An egg crate mattress under the head is also a nursing intervention that can help prevent skin breakdown. Proteinuria is not specific to hydrocephalus. Stimulus needs to be kept at a minimum because of the increase in ICP. It is not necessary to check the blood pressure every 15 minutes.

Test-Taking Strategy: Note the **strategic word,** *priority.* Focus on the child's diagnosis. Eliminate option 4 because of the words *15 minutes*. From the remaining options, recall that because of the severe head enlargement, the nursing intervention that has priority is to reposition the infant frequently to prevent the development of pressure areas.

Reference: Lowdermilk, D., Perry, S., Cashion, K., Alden, K., & Olshansky, E. (2020). *Maternity & women's health care.* (12th ed.). St. Louis: Elsevier. p. 791.

11. *Answer:* 1, 3, 5

Rationale: A seizure is a disorder that occurs as a result of excessive and unorganized neuronal discharges in the brain that activate associated motor and sensory organs. During a seizure, the child is placed on the side. Positioning on the side prevents aspiration, because saliva drains out the corner of the child's mouth. The child is not restrained because this could cause injury to the child. The nurse would loosen clothing around the child's neck and ensure a patent airway. Nothing is placed into the child's mouth during a seizure, because this action may cause injury to the child's mouth, gums, or teeth. The nurse would stay with the child to reduce the risk of injury and allow for observation and timing of the seizure.

Test-Taking Strategy: Focus on the **subject** and visualize this clinical situation. Recalling that airway patency and safety are the priorities will assist in determining the appropriate interventions.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1151.

CHAPTER 40

Musculoskeletal Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

PRIORITY CONCEPTS Development; Mobility

I. Developmental Dysplasia of the Hip

A. Description

1. Problems related to abnormal development of the hip that may develop during fetal life, infancy, or childhood; in these problems, the head of the femur is seated improperly in the acetabulum, or hip socket, of the pelvis.

2. Degrees of developmental dysplasia of the hip (Box 40.1)

B. Assessment (Fig. 40.1)

1. Neonate: Laxity of the ligaments around the hip

2. Infant

a. Shortening of the limb on the affected side (Galeazzi sign, also known as *Allis sign*)

b. Restricted abduction of the hip on the affected side when the infant is placed supine with knees and hips flexed (limited range of motion in the affected hip)

c. Unequal gluteal folds when the infant is prone and legs are extended against the examining table

d. Positive Ortolani's test: Ortolani's maneuver is a test to assess for hip instability. The examiner abducts the thigh and applies gentle pressure forward over the greater trochanter. A "clicking" sensation indicates a dislocated femoral head moving into the acetabulum.

e. Positive Barlow's test: The examiner adducts the hips and applies gentle pressure down and back with the thumbs. In hip dysplasia, the examiner can feel the femoral head move out of the acetabulum.

3. Older infant and child

a. Affected leg is shorter than the other.

b. The head of the femur can be felt to move up and down in the buttock when the extended thigh is pushed first toward the child's head and then pulled distally.

c. Positive Trendelenburg's sign: The child stands on one foot and then the other foot, holding on to a support and bearing weight on the affected hip; the pelvis tilts downward on the normal side instead of upward, as it would with normal stability.

d. Greater trochanter is prominent.

e. Marked lordosis or waddling gait is noted in bilateral dislocations.

C. Interventions

1. Birth to 6 months of age: Splinting of the hips with a Pavlik harness to maintain flexion and abduction and external rotation; the harness is worn continuously for 23 hours per day until hip is stable, usually within 6 to12 weeks; it is removed only for bathing purposes (Fig. 40.2).

2. Age 6 to 18 months: Gradual reduction by **traction** followed by closed reduction or open reduction (if necessary) under general anesthesia. The

BOX 40.1 Degrees of Developmental Dysplasia of the Hip

Acetabular Dysplasia (Preluxation)

- Mildest form
- Neither subluxation nor dislocation
- Delay in acetabular development occurs.
- Femoral head remains in acetabulum.

Subluxation

- Incomplete dislocation of the hip
- Femoral head remains in acetabulum.
- Stretched capsule and ligamentum teres cause the head of the femur to be partially displaced.

Dislocation

- Femoral head loses contact with acetabulum and is displaced posteriorly and superiorly over fibrocartilaginous rim.
- Ligamentum teres is elongated and taut.

Telegram & Insta: NCLEX_RN_Edu

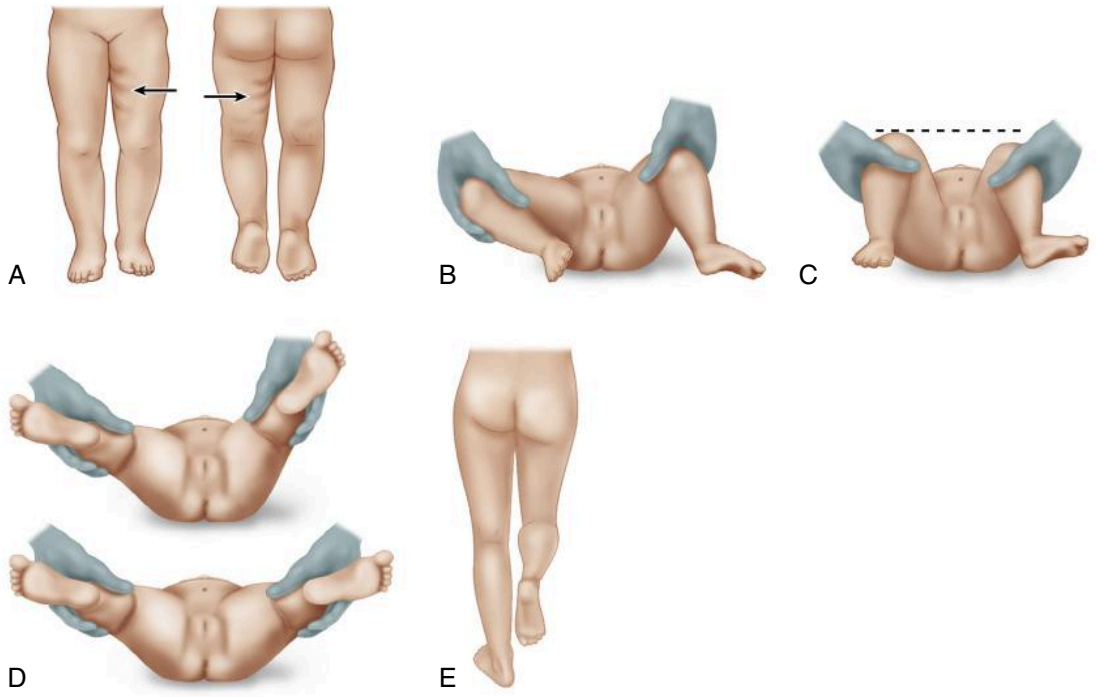

FIG. 40.1 Signs of developmental dysplasia of the hip. **A,** Asymmetry of gluteal and thigh folds. **B,** Limited hip abduction, as seen in flexion. **C,** Apparent shortening of the femur, as indicated by the level of the knees in flexion. **D,** Ortolani click (if infant is younger than 4 weeks old). **E,** Positive Trendelenburg's sign or gait (if child is weight-bearing).

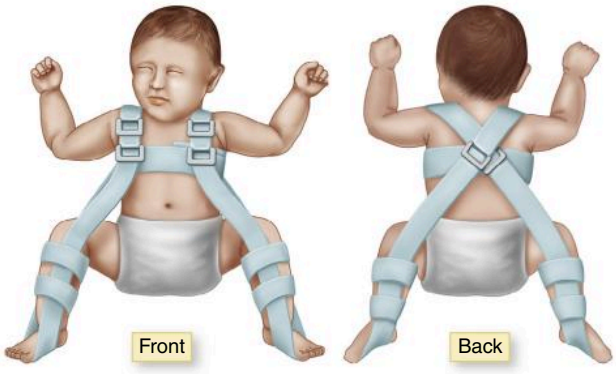

FIG. 40.2 Child in Pavlik harness.

child is then placed in a hip spica cast for 6 to 12 weeks until the hip is stable; then a flexion-abduction brace is continued for 6 weeks.

3. Older child: Operative reduction and reconstruction is usually required.
4. Parents are instructed regarding proper care of a Pavlik harness, spica cast, or abduction brace.

II. Congenital Clubfoot

A. Description

1. Complex deformity of the ankle and foot that includes forefoot adduction, midfoot supination, hindfoot varus, and ankle equinus; defect may be unilateral or bilateral.
2. The goal of treatment is to achieve a painless plantigrade (able to walk on the sole of the foot with the heel on the ground) and stable foot.

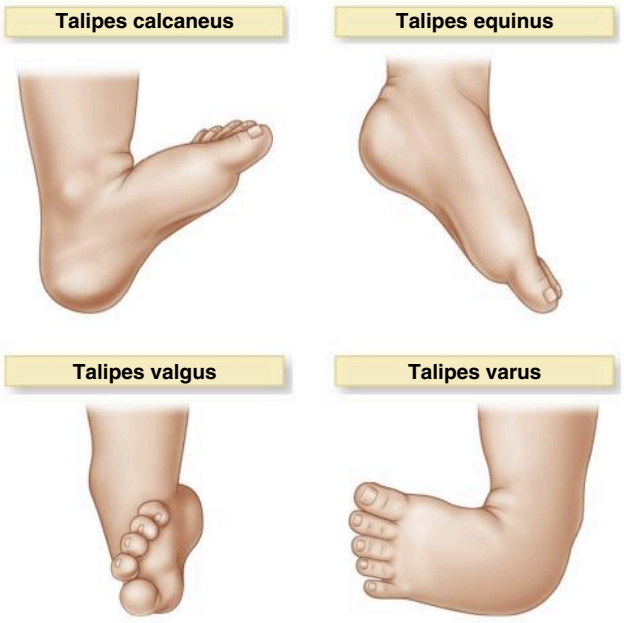

FIG. 40.3 Talipes clubfoot deformity positions.

3. Long-term interval follow-up care is required until the child reaches skeletal maturity.

B. Assessment: Deformities are described on the basis of the position of the ankle and foot (Fig. 40.3).

1. Talipes varus: Inversion or bending inward
2. Talipes valgus: Eversion or bending outward
3. Talipes equinus: Plantar flexion in which the toes are lower than the heel
4. Talipes calcaneus: Dorsiflexion in which the toes are higher than the heel

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

C. Interventions
1. Treatment begins as soon after birth as possible.
2. Manipulation and casting are performed weekly for about 8 to 12 weeks because of the rapid growth of early infancy; a splint is then applied if casting and manipulation are successful.
3. Surgical intervention may be necessary if normal alignment is not achieved by about 6 to 12 weeks of age.
4. Monitor for pain, and monitor the neurovascular status of the toes.

Contact the primary health care provider (PHCP) immediately if signs of neurovascular impairment are noted in a child with a cast or brace.

III. Idiopathic Scoliosis

A. Description
1. Three-dimensional spinal deformity that usually involves lateral curvature, spinal rotation resulting in rib asymmetry, and hypokyphosis of the thorax
2. Idiopathic scoliosis usually is diagnosed during the preadolescent growth spurt; screenings are important when growth spurts occur.
3. Surgical (spinal fusion, which may be done by thoracoscopic surgery, placement of an instrumentation system, or use of metallic staples placed into vertebral bodies) and nonsurgical (bracing) interventions are used; the type of treatment depends on the location and degree of the curvatures, the age of the child, the amount of growth that is yet anticipated, and any underlying disease processes.
4. Long-term monitoring is essential to detect any progression of the curve.

B. Assessment
1. Asymmetry of the ribs and flanks is noted when the child bends forward at the waist and hangs the arms down toward the feet (Adam's test).
2. Hip height, rib positioning, and shoulder height are asymmetrical (can be noted when standing behind an undressed child); leg length discrepancy is also apparent.
3. Radiographs are obtained to confirm the diagnosis.

C. Interventions
1. Monitor progression of the curvatures.
2. Prepare the child and parents for the use of a brace if prescribed.
3. Prepare the child and parents for surgery (spinal fusion, placement of internal instrumentation systems) if prescribed.

The potential for altered role performance, body image disturbance, fear, anger, and isolation exists for a child with a disabling condition and a condition that requires wearing a body brace.

D. Braces
1. Braces are not curative but may slow the progression of the curvature to allow skeletal growth and maturity.
2. Braces usually are prescribed to be worn 16 to 23 hours a day.
3. Inspect the skin for signs of redness or breakdown.
4. Keep the skin clean and dry, and avoid lotions and powders, because these cake and lead to skin breakdown.
5. Advise the child to wear soft, nonirritating clothing under the brace.
6. Instruct in prescribed exercises (exercises help maintain and strengthen spinal and abdominal muscles during treatment).
7. Encourage verbalization about body image and other psychosocial issues.

E. Postoperative interventions
1. Maintain proper alignment; avoid twisting movements.
2. Logroll the child when turning to maintain alignment.
3. Assess extremities for adequate neurovascular status.
4. Encourage coughing and deep breathing and the use of incentive spirometry.
5. Assess pain and administer prescribed analgesics.
6. Monitor for incontinence.
7. Monitor for signs and symptoms of infection.
8. Monitor for superior mesenteric artery syndrome (caused by mechanical changes in the position of the child's abdominal contents during surgery), and notify the PHCP if it occurs; symptoms include emesis and abdominal distention similar to what occurs with intestinal obstruction or paralytic ileus.
9. Instruct in activity restrictions.
10. Instruct the child how to roll from a side-lying position to a sitting position, and assist with ambulation.
11. Address a potential body image disturbance when formulating a plan of nursing care.

IV. Juvenile Idiopathic Arthritis

A. Description
1. Autoimmune inflammatory disease affecting the joints and other tissues, such as articular cartilage.
2. Treatment is supportive (there is no cure) and directed toward preserving joint function, controlling inflammation, minimizing deformity, and reducing the impact that the disease may have on the development of the child.
3. Treatment includes medications, physical and occupational therapies, and child and family education.
4. A pediatric rheumatology team can manage the complex needs of the child and family most effectively. The team may consist of a pediatric

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

rheumatologist, physical and occupational therapist, social worker, and nurse specialist.

5. Surgical intervention may be implemented if the child has problems with joint contractures and unequal growth of extremities.

B. Assessment (Box 40.2)

1. There are no definitive tests to diagnose juvenile idiopathic arthritis.
2. Some laboratory tests, such as an elevated erythrocyte sedimentation rate or determination of the presence of leukocytosis, may support evidence of the disease.
3. Radiographs may show soft tissue swelling and joint space widening from increased synovial fluid in the joint.

C. Interventions

1. Facilitate social and emotional development.
2. Instruct parents and child in the administration of medications; medications may be given alone or in combination and are prescribed depending on the progression of the disease (Box 40.3).
3. Assist the child with range-of-motion exercises and instruct in prescribed exercises.
4. Encourage normal performance of activities of daily living.
5. Instruct parents and child in the use of hot or cold packs, splinting, and positioning the affected joint in a neutral position during painful episodes. Begin simple isometric exercises as soon as the child is able.
6. Encourage and support prescribed physical and occupational therapy.
7. Instruct in the importance of preventive eye care and reporting visual disturbances.
8. Assess the child's and family's perceptions regarding the chronic illness; plan to discuss the nature of a chronic illness and the associated life alterations that result from the chronic progression of the disorder.

BOX 40.2 Assessment Findings: Juvenile Idiopathic Arthritis

- Stiffness, swelling, and limited motion occur in affected joints.
- Affected joints are warm to touch, tender, and painful.
- Joint stiffness is present on arising in the morning and after inactivity.
- Uveitis (inflammation of structures in the uveal tract) can occur and cause blindness.

BOX 40.3 Medications Used in Juvenile Idiopathic Arthritis

Corticosteroid injections: Prescribed when only a few joints are involved. Usually do not have any significant side effects.

Oral corticosteroids: May be prescribed but only for a short time and at the lowest dose possible. Long-term use is associated with side effects such as weight gain, poor growth, osteoporosis, cataracts, avascular necrosis, hypertension, and risk of infection.

Disease-modifying antirheumatic drugs (DMARDs): Prescribed as a second-line treatment when many joints are involved or the child does not respond to corticosteroid joint injections. Biologics may also be prescribed, and these include antitumor necrosis factor agents. All of these medications cause side effects that need to be discussed with the child and/or parents.

V. Marfan's Syndrome

A. Description

1. Disorder of connective tissue that primarily affects the skeletal, cardiovascular, and ocular systems. (There may also be lung, skin, and central nervous system involvement.)
2. Marfan's syndrome is caused by defects in the fibrillin-1 gene, which serves as a building block for elastic tissue in the body; also, the disorder may be inherited.
3. There is no cure for the disorder.

B. Assessment

1. Tall and thin body structure: slender fingers, long arms and legs, curvature of the spine
2. Presence of visual problems
3. Presence of cardiac problems

C. Interventions

1. Monitor for vision problems, and obtain visual examinations on a regular schedule.
2. Monitor for curvature of the spine, especially during adolescence.
3. Cardiac medications may be prescribed to slow the heart rate to decrease stress on the aorta.
4. Instruct parents that the child needs to avoid participating in competitive athletics and contact sports to avoid injuring the heart.
5. Instruct parents to inform the dentist of the condition; antibiotics need to be taken before dental procedures to prevent endocarditis.
6. Surgical replacement of the aortic root and valve may be necessary.

VI. Legg-Calvé-Perthes Disease

A. Description

1. A condition affecting the hip where the femur and pelvis meet in the joint
2. Blood supply is temporarily interrupted to the head of the femur, and the bone dies and stops growing.

B. Assessment

1. Limping
2. Pain or stiffness in the hip, groin, thigh, or knee

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Limited range of motion in the affected joint

C. Interventions
   1. Physical therapy, particularly stretching exercises
   2. Use of crutches to avoid bearing weight on the affected hip
   3. Bed rest and traction if pain is severe
   4. Casting to keep the femoral head within its socket
   5. Use of a nighttime brace
   6. Hip replacement surgery

VII. Fractures

A. Description (see also Chapter 61)
   1. A break in the continuity of the bone as a result of trauma, twisting, or bone decalcification
   2. Fractures in children usually occur as a result of increased mobility and inadequate or immature motor and cognitive skills; they may result from trauma or bone diseases such as congenital bone disease or bone tumors.
   3. Types (see Chapter 61)

Fractures in infancy are generally rare and warrant further investigation to rule out the possibility of child abuse and to identify bone structure defects.

B. Assessment
   1. Pain or tenderness over the involved area
   2. Obvious deformity
   3. Edema
   4. Ecchymosis
   5. Muscle spasm
   6. Loss of function
   7. Crepitation

C. Initial care of a fracture (see Clinical Judgment: Take Action Box)

CLINICAL JUDGMENT: TAKE ACTION

A 12-year-old child falls off a trampoline in the school playground. The school nurse quickly arrives at the scene of the accident. The child is alert but crying and moaning in pain. The child states "I didn't hit my head but twisted my leg badly and it is really hurting, and I cannot move it." On assessment of the extent of the injury, the nurse notes an obvious deformity of the lower right leg, swelling, and the presence of bone protruding from an open wound. The nurse takes the following actions:

- Immobilizes the extremity
- Checks neurovascular status of the extremity
- Covers the wound with a sterile dressing (clean dressing if a sterile dressing is unavailable)
- Elevates the injured extremity if possible
- Applies cold to the area
- Arranges for immediate transport to the nearest emergency department

D. Interventions
   1. Reduction
      a. Restoring the bone to proper alignment
      b. Closed reduction: Accomplished by manual alignment of the fragments, followed by immobilization
      c. Open reduction: Surgical insertion of internal fixation devices, such as rods, wires, or pins, to help maintain alignment while healing occurs
   2. Retention: Application of traction or a cast to maintain alignment until healing occurs

E. Traction (also see Chapter 61)
   1. Russell skin traction
      a. Used to stabilize a fractured femur before surgery
      b. Similar to Buck's traction but provides a double pull using a knee sling that pulls at the knee and foot
   2. Balanced suspension
      a. Used with skin or skeletal traction to approximate fractures of the femur, tibia, or fibula
      b. Balanced suspension is produced by a counterforce other than the child.
      c. Provide pin care if pins are used with the skeletal traction.
   3. 90-degree–90-degree traction
      a. The lower leg is supported by a boot cast or a calf sling.
      b. A skeletal Steinmann pin or Kirschner wire is placed in the distal fragment of the femur, allowing 90-degree flexion at the hip and the knee.
   4. Interventions
      a. Maintain correct amount of weight as prescribed.
      b. Ensure that weights hang freely.
      c. Check all ropes for fraying and all knots for tightness; be sure that the ropes are appropriately tracking in the grooves of the pulley wheels.
      d. Monitor neurovascular status of the involved extremity.
      e. Protect the skin from breakdown.
      f. Monitor for signs and symptoms of complications of immobilization, such as constipation, skin breakdown, lung congestion, renal complications, and disuse syndrome of unaffected extremities.
      g. Provide therapeutic and diversional play.

F. Casts (also see Chapter 61)
   1. Description
      a. Made of plaster or fiberglass to provide immobilization of bone and joints after a fracture or injury
      b. Fractures of the hip or knee may require a spica cast.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Interventions
   a. Examine the cast for pressure areas.
   b. Ensure that no rough casting material remains in contact with the skin; petal the cast edges with waterproof adhesive tape or moleskin as necessary to ensure a smooth cast edge.
   c. If a hip spica cast is placed, the cast edges around the perineum and buttocks may need to be taped with waterproof tape.
   d. Monitor the extremity for circulatory impairment, such as pain greater than that expected for the type of injury, edema, rubor, pallor, numbness and tingling, coolness, decreased sensation or mobility, diminished pulse, or signs of **compartment syndrome**.
   e. Notify the PHCP if circulatory impairment occurs.
   f. Prepare for bivalving or cutting the cast if circulatory impairment occurs; prepare for emergency fasciotomy if cast removal does not improve the neurocirculatory compromise.
   g. Instruct parents and child not to stick objects down the cast. Monitor for "hot spots."
   h. Teach parents and child to keep the cast clean and dry.
   i. Instruct parents and child in isometric exercises to prevent muscle atrophy.

VIII. Osteomyelitis (also see Chapter 61)

A. Description
   1. An infectious process in the bone
   2. Common causative organism is *Staphylococcus aureus*

B. Assessment
   1. Pain
   2. Fever
   3. Irritability
   4. Lethargy
   5. Extremity warmth, tenderness, and decreased range of motion

C. Interventions
   1. Acute phase: Use positions of comfort, temporary splints/casts, non–weight bearing.
   2. Initiate antibiotics after appropriate cultures are obtained.
   3. Aggressive long-term antibiotics may be necessary and require the use of a central venous line (PICC).
   4. Surgery may be indicated if antibiotic response is ineffective.
   5. Administer pain medication.
   6. Initiate physical therapy and occupational therapy as prescribed.
   7. Initiate developmentally appropriate activities.

PRACTICE QUESTIONS

1. A child has a right femur fracture caused by a motor vehicle crash and is placed in skin traction temporarily until surgery can be performed. During assessment, the nurse notes that the dorsalis pedis pulse is absent on the right foot. Which action would the nurse take?
   1. Administer an analgesic.
   2. Release the skin traction.
   3. Apply ice to the extremity.
   4. Notify the primary health care provider (PHCP).

2. A child is placed in skeletal traction for treatment of a fractured femur. The nurse creates a plan of care and would include which intervention?
   1. Ensure that all ropes are outside the pulleys.
   2. Ensure that the weights are resting lightly on the floor.
   3. Restrict diversional and play activities until the child is out of traction.
   4. Check the primary health care provider's (PHCP's) prescriptions for the amount of weight to be applied.

3. A 4-year-old child sustains a fall at home. After an x-ray examination, the child is determined to have a fractured arm, and a plaster cast is applied. The nurse provides instructions to the parents regarding care for the child's cast. Which statement by the parents indicates a **need for further instruction**?
   1. "The cast may feel warm as the cast dries."
   2. "I can use lotion or powder around the cast edges to relieve itching."
   3. "A small amount of white shoe polish can touch up a soiled white cast."
   4. "If the cast becomes wet, a blow-dryer set on the cool setting may be used to dry the cast."

4. The parents of a child with juvenile idiopathic arthritis call the clinic nurse because the child is experiencing a painful exacerbation of the disease. The parents ask the nurse if the child can perform range-of-motion exercises at this time. The nurse would make which response?
   1. "Avoid all exercise during painful periods."
   2. "Range-of-motion exercises must be performed every day."
   3. "Have the child perform simple isometric exercises during this time."
   4. "Administer additional pain medication before performing range-of-motion exercises."

5. A child who has undergone spinal fusion for scoliosis complains of abdominal discomfort and begins to have episodes of vomiting. On further assessment, the nurse notes abdominal distention.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

On the basis of these findings, the nurse would take which action?
1. Administer an antiemetic.
2. Increase the intravenous fluids.
3. Place the child in a left lateral position.
4. Notify the primary health care provider (PHCP).

6. The nurse is providing instructions to the parents of a child with scoliosis regarding the use of a brace. Which statement by the parents indicates a **need for further instruction**?
1. "I will encourage my child to perform prescribed exercises."
2. "I will have my child wear soft fabric clothing under the brace."
3. "I need to apply lotion under the brace to prevent skin breakdown."
4. "I need to avoid the use of powder because it will cake under the brace."

7. The nurse is assisting a primary health care provider (PHCP) in the examination of a 3-week-old infant with developmental dysplasia of the hip. What test or sign would the nurse expect the PHCP to assess?
1. Babinski's sign
2. The Moro reflex
3. Ortolani's maneuver
4. The palmar-plantar grasp

8. A 1-month-old infant is seen in a clinic and is diagnosed with developmental dysplasia of the hip. On assessment, the nurse understands that which finding would be noted in this condition?
1. Limited range of motion in the affected hip
2. An apparent lengthened femur on the affected side
3. Asymmetrical adduction of the affected hip when the infant is placed supine with the knees and hips flexed
4. Symmetry of the gluteal skinfolds when the infant is placed prone and the legs are extended against the examining table

9. Parents bring their 2-week-old infant to a clinic for treatment after a diagnosis of clubfoot made at birth. Which statement by the parents indicates a **need for further teaching** regarding this disorder?
1. "Treatment needs to be started as soon as possible."
2. "I realize my infant will require follow-up care until fully grown."
3. "I need to bring my infant back to the clinic in 1 month for a new cast."
4. "I need to come to the clinic every week with my infant for the casting."

10. The nurse prepares a list of home care instructions for the parents of a child who has a plaster cast applied to the left forearm. Which instructions would be included on the list? **Select all that apply.**
- ❑ 1. Use the fingertips to lift the cast while it is drying.
- ❑ 2. Keep small toys and sharp objects away from the cast.
- ❑ 3. Use a padded ruler or another padded object to scratch the skin under the cast if it itches.
- ❑ 4. Place a heating pad on the lower end of the cast and over the fingers if the fingers feel cold.
- ❑ 5. Elevate the extremity on pillows for the first 24 to 48 hours after casting to prevent swelling.
- ❑ 6. Contact the primary health care provider (PHCP) if the child complains of numbness or tingling in the extremity.

ANSWERS

1. *Answer:* 4

Rationale: An absent pulse to an extremity of the affected limb after a bone fracture could mean that the child is developing or experiencing compartment syndrome. This is an emergency situation, and the PHCP needs to be notified immediately. Administering analgesics would not improve circulation. The skin traction would not be released without a PHCP's prescription. Applying ice to an extremity with absent perfusion will worsen the problem. Ice may be prescribed when perfusion is adequate to decrease swelling.

Test-Taking Strategy: Use the ABCs—airway, breathing, and circulation. Focus on the data in the question, which indicate that circulation is impaired. This will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1264-1265.

2. *Answer:* 4

Rationale: When a child is in traction, the nurse would check the PHCP's prescription to verify the prescribed amount of traction weight. The nurse would maintain the correct amount of weight as prescribed, ensure that the weights hang freely, check the ropes for fraying and ensure that they are on the pulleys appropriately, monitor the neurovascular status of the involved extremity, and monitor for signs and symptoms of complications of immobilization. The nurse would provide therapeutic and diversional play activities for the child.

Test-Taking Strategy: Focus on the subject, care of the child in traction. Eliminate option 3 first because of the word *restrict.*

Telegram & Insta: NCLEX_RN_Edu

Next recall the general principles related to traction, recalling that weights need to hang freely and that ropes would remain in the pulleys.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1254.

3. *Answer:* 2
Rationale: Teaching about cast care is essential to prevent complications from the cast. The parents need to be instructed not to use lotion or powders on the skin around the cast edges or inside the cast. Lotions or powders can become sticky or caked and cause skin irritation. Options 1, 3, and 4 are appropriate statements and indicate that the parents understand cast care.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Remember that lotions or powders can become sticky or caked and cause skin irritation.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1252-1253.

4. *Answer:* 3
Rationale: Juvenile idiopathic arthritis is an autoimmune inflammatory disease affecting the joints and other tissues, such as articular cartilage. During painful episodes of juvenile idiopathic arthritis, hot or cold packs and splinting and positioning the affected joint in a neutral position help reduce the pain. Although resting the extremity is appropriate, beginning simple isometric or tensing exercises as soon as the child is able is important. These exercises do not involve joint movement.
Test-Taking Strategy: Focus on the **subject,** exercise during an acute exacerbation of the disease. Eliminate options 1 and 2 because of the **closed-ended words** "all" and "must," and option 4 because of the word *additional*.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1289.

5. *Answer:* 4
Rationale: Scoliosis is a three-dimensional spinal deformity that usually involves lateral curvature, spinal rotation resulting in rib asymmetry, and hypokyphosis of the thorax. A complication after surgical treatment of scoliosis is superior mesenteric artery syndrome. This disorder is caused by mechanical changes in the position of the child's abdominal contents, resulting from lengthening of the child's body. The disorder results in a syndrome of emesis and abdominal distention similar to that which occurs with intestinal obstruction or paralytic ileus. Postoperative vomiting in children with body casts or children who have undergone spinal fusion warrants attention because of the possibility of superior mesenteric artery syndrome. Options 1, 2, and 3 are incorrect.
Test-Taking Strategy: Focus on the **data in the question** and think about the complications that can occur after surgical treatment for scoliosis. Eliminate option 2 first because it would not be implemented unless prescribed by the PHCP. Eliminate option 3 next because this child requires logrolling, and the left lateral position may cause injury after surgery. From the remaining options, note the assessment signs and symptoms in the question. These would alert you that notification of the PHCP is necessary.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 689, 1278.

6. *Answer:* 3
Rationale: A brace may be prescribed to treat scoliosis. Braces are not curative but may slow the progression of the curvature to allow skeletal growth and maturity. The use of lotions or powders under a brace needs to be avoided because they can become sticky and cake under the brace, causing irritation. Options 1, 2, and 4 are appropriate interventions in the care of a child with a brace.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Careful reading of the options and applying the principles associated with cast care will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p.1298.

7. *Answer:* 3
Rationale: In developmental dysplasia of the hip, the head of the femur is seated improperly in the acetabulum or hip socket of the pelvis. Ortolani's maneuver is a test to assess for hip instability and can be done only before 4 weeks of age. The examiner abducts the thigh and applies gentle pressure forward over the greater trochanter. A "clicking" sensation indicates a dislocated femoral head moving into the acetabulum. Babinski's sign is abnormal in anyone older than 2 years of age and indicates central nervous system abnormality. The Moro reflex is normally present at birth but is absent by 6 months; if still present at 6 months, there is an indication of neurological abnormality. The palmar-plantar grasp is present at birth and lessens within 8 months.
Test-Taking Strategy: Options 1 and 2 can be eliminated first because they are **comparable or alike** and are both tests of neurological function. To select the correct answer from the remaining options, remember that Ortolani's maneuver is an assessment technique for hip dysplasia that can only be done before 4 weeks of age.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p.1280.

8. *Answer:* 1
Rationale: In developmental dysplasia of the hip, the head of the femur is seated improperly in the acetabulum or hip socket of the pelvis. Asymmetrical and restricted abduction of the affected hip when the child is placed supine with the knees and hips flexed would be an assessment finding in developmental dysplasia of the hip in infants beyond the newborn period. Other findings include an apparent short femur on the affected side, asymmetry of the gluteal skinfolds, and limited range of motion in the affected extremity.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Note the **subject,** assessment findings in developmental dysplasia of the hip. Also, note the age of the infant and focus on the infant's diagnosis. Visualizing each of the assessment findings described in the options will direct you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1280.

9. *Answer:* 3
Rationale: Clubfoot is a complex deformity of the ankle and foot that includes forefoot adduction, midfoot supination, hindfoot varus, and ankle equinus; the defect may be unilateral or bilateral. Treatment for clubfoot is started as soon as possible after birth. Serial manipulation and casting are performed at least weekly. If sufficient correction is not achieved in 3 to 6 months, surgery usually is indicated. Because clubfoot can recur, all children with clubfoot require long-term interval follow-up until they reach skeletal maturity to ensure an optimal outcome.
Test-Taking Strategy: Note the **strategic words,** *need for further teaching*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. This will assist you in eliminating options 1 and 2. Recalling that serial manipulations and casting are required weekly will assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1284.

10. *Answer:* 2, 5, 6
Rationale: While the cast is drying, the palms of the hands are used to lift the cast. If the fingertips are used, indentations in the cast could occur and cause constant pressure on the underlying skin. Small toys and sharp objects are kept away from the cast, and no objects (including padded objects) are placed inside the cast because of the risk of altered skin integrity. The extremity is elevated to prevent swelling, and the PHCP is notified immediately if any signs of neurovascular impairment develop. A heating pad is not applied to the cast or fingers. Cold fingers could indicate neurovascular impairment, and the PHCP would be notified.
Test-Taking Strategy: Use of the **ABCs—airway, breathing, and circulation—**and safety principles related to care of a child with a cast will assist in answering this question.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1253.

CHAPTER 41

Immune Problems and Infectious Diseases

Contributor: Necole Leland, DNP, RN, PNP, CPN

PRIORITY CONCEPTS Infection; Safety

I. Immune Problems: For information on the functions of the immune system, the immune response, immunodeficiency, other immune disorders, hypersensitivity and allergies, and skin testing, see Chapter 63.

⚠ Standard precautions are instituted in the care of all children. Additional transmission-based precautions, such as airborne, droplet, or contact precautions, may also need to be instituted, depending on the child's disease, its method of transmission, and other conditions present in the child. For example, in addition to standard precautions, the nurse may need to institute droplet or airborne precautions for a child with influenza, but if that same child has a wound infection or scabies, then contact precautions are also necessary.

II. Human Immunodeficiency Virus Infection and Acquired Immunodeficiency Syndrome

A. Description

1. Acquired immunodeficiency syndrome (AIDS) is a disorder caused by human immunodeficiency virus (HIV) and characterized by generalized dysfunction of the immune system (see Chapter 63, Fig. 63.1).
2. The diagnosis of AIDS is associated with certain illnesses or conditions.
3. HIV infects $CD4^+$ T cells; a gradual decrease in $CD4^+$ T-cell count occurs, and this results in a progressive immunodeficiency. The risk for opportunistic infections is present (Box 41.1).
4. HIV is transmitted through blood, semen, vaginal secretions, and human milk; the incubation period is months to years.
5. Horizontal transmission occurs through intimate sexual contact or parenteral exposure to blood or body fluids that contain the virus.
6. Vertical (perinatal) transmission occurs from an HIV-infected pregnant person to the fetus (see Chapter 23).
7. The most common opportunistic infection that occurs in children infected with HIV is *Pneumocystis jiroveci* pneumonia; *P. jiroveci* pneumonia most frequently occurs between the ages of 3 and 6 months.

⚠ An infant or child infected with HIV is at risk for developing a life-threatening opportunistic infection. Monitor the infant or child closely for signs of infection and report these signs immediately if they occur.

B. Assessment (see Box 41.1 and Box 41.2)

C. Diagnostic tests

1. Before testing, counseling would be provided to parents; issues that need to be addressed include the causes of HIV, reasons for testing, implications of positive test results, confidentiality issues, and beneficial effects of early intervention (Table 41.1).
2. For the latest information about diagnostic testing, refer to Centers for Disease Control and Prevention: Diagnostic Tests, at https://www.cdc.gov/hiv/clinicians/screening/diagnostic-tests.HTML

III. Care of the Child with HIV Infection or AIDS

A. An interprofessional health care approach is taken; primary goals are to decelerate the replication of the virus, prevent opportunistic infections, provide nutritional support, treat symptoms, and treat opportunistic infections.

B. Prophylaxis (*P. jiroveci* pneumonia and other opportunistic infections)

1. Provide prophylaxis as prescribed against *P. jiroveci* pneumonia and other opportunistic infections, particularly during the first year of life of an infant born to an HIV-infected birthing parent.

Telegram & Insta: NCLEX_RN_Edu

BOX 41.1 Common Acquired Immunodeficiency Syndrome (AIDS)–Defining Conditions in Children

- Candidal esophagitis
- Cryptosporidiosis
- Cytomegalovirus disease
- Herpes simplex disease
- Human immunodeficiency virus encephalopathy
- Lymphoid interstitial pneumonitis
- *Mycobacterium avium-intracellulare* infection
- *Pneumocystis jiroveci* pneumonia
- Pulmonary candidiasis
- Recurrent bacterial infections
- Wasting syndrome

Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1061.

BOX 41.2 Common Assessment Findings in Children with Human Immunodeficiency Virus (HIV) Infection

- Chronic cough
- Chronic or recurrent diarrhea
- Developmental delay or regression of developmental milestones
- Failure to thrive
- Hepatosplenomegaly
- Lymphadenopathy
- Malaise and fatigue
- Night sweats
- Oral candidiasis
- Parotitis
- Weight loss

Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1061.

TABLE 41.1 Tests for Human Immunodeficiency Virus (HIV)[a]

Test	Age-Appropriate Use	Test Determines	Special Considerations
Enzyme-linked immunosorbent assay (ELISA)	≥18 mo	Response of antibodies to HIV	If used and found to be positive in infants <18 mo, indicates only that birth parent is infected because birthing parent antibodies are transmitted transplacentally; follow-up with another diagnostic test (HIV differential assay)
Western blot	≥18 mo	Presence of HIV antibodies	Not used to diagnose HIV. May be used to confirm a positive ELISA
Polymerase chain reaction	<18 mo	Presence of proviral DNA	Very accurate for diagnosing infants 1-4 mo of age
p24 antigen	<18 mo	HIV antigen specific	Very accurate for diagnosing infants 1-4 mo of age
$CD4^+$ lymphocyte count, T-lymphocyte count	Infant–13 yr	Immune system status related specifically to suppression	Age adjustment is essential, because normal counts are relatively high in infants and steadily decline until 6 yr of age. Severe suppression in all age groups is <15% total lymphocytes (<750 cells/L in infant <12 mo, <500 cells/L in child 1-5 yr, <200 cells/L in child 6-12 yr)

[a]Note: For the latest information about diagnostic testing, refer to Centers for Disease Control and Prevention: Diagnostic Tests, at https://www.cdc.gov/hiv/clinicians/screening/diagnostic-tests.HTML

2. After 1 year of age, the need for prophylaxis is determined on the basis of the presence and severity of immunosuppression or a history of *P. jiroveci* pneumonia.
3. Continuing prophylaxis is based on the child's HIV status, history of opportunistic infections, and $CD4^+$ counts.

C. Antiretroviral medications (refer to Chapter 64)

⚠ Before administering an antiretroviral medication, ensure that the medication is safe for pediatric administration. Also check the contraindications for use and the adverse effects.

1. The goal of antiretroviral medications is to suppress viral replication to slow the decline in the number of $CD4^+$ cells, preserve immune function, reduce the incidence and severity of opportunistic infections, and delay disease progression.
2. The medications affect different stages of the HIV life cycle to prevent reproduction of new virus particles.
3. Combination therapy may be prescribed and includes the use of more than one antiretroviral medication.

D. Immunizations (refer to Chapter 19 for specific information on childhood immunizations)

⚠ Immunization against childhood diseases is recommended for all children exposed to and infected with HIV.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

1. If a child has symptomatic HIV infection or has severe immunosuppression, guidelines are as follows:
   a. Only the inactivated influenza vaccine that is given intramuscularly would be used (influenza vaccine needs to be given yearly).
   b. Measles vaccine would not be given; immunoglobulin may be prescribed after measles exposure.
   c. Only the inactivated polio vaccine that is given intramuscularly would be used.
   d. Rotavirus vaccine would not be given.
   e. Varicella-zoster virus vaccine would not be given; varicella-zoster immunoglobulin may be prescribed after exposure to chicken pox.
   f. Tetanus immunoglobulin may be prescribed for tetanus-prone wounds.

E. Caregiver instructions
1. Wash hands frequently.
2. Assess the child for fever, malaise, fatigue, weight loss, vomiting, diarrhea, altered activity level, and oral lesions; notify the pediatrician if any of these occur.
3. Assess the child for signs and symptoms of opportunistic infections, such as pneumonia.
4. Administer antiretroviral medications and other medications to the child as prescribed.
5. The child needs to be restricted from having contact with persons who have infections or other contagious or potentially contagious illnesses.
6. Keep the child's immunizations up to date.
7. Keep the child home when sick.
8. Avoid direct unprotected contact with the child's body fluids.
9. Monitor the child's weight.
10. Provide a high-calorie and high-protein diet to the child.
11. Administer appetite stimulants to the child as prescribed and as needed.
12. Do not share eating utensils with the child.
13. Wash all eating utensils in the dishwasher.
14. Cover any of the child's unused food and formula and refrigerate (discard unused refrigerated formula and food after 24 hours).
15. Do not allow the child to eat fresh fruits or vegetables or raw meat or fish (neutropenic diet if immunosuppressed).
16. Wear gloves when caring for the child, especially when in contact with body fluids and changing diapers.
17. Change the child's diapers frequently, away from food areas.
18. Fold the child's soiled disposable diapers inward, close with the tabs, and dispose of in a tightly covered plastic-lined container.
19. Dispose of trash daily.
20. Clean up any of the child's body fluid spills with a bleach solution (10:1 ratio of water to bleach).

F. Education for an adolescent infected with HIV
1. Educate about high-risk behaviors and the importance of avoiding high-risk behaviors.
2. Identify the methods of transmission of HIV.
3. Emphasize the importance of abstinence from sexual contact, such as intercourse.
4. Emphasize the importance of using safe condoms if intercourse is planned.
5. Identify the resources available for support and other issues.

IV. Rubeola (Measles)

A. Description
1. Agent: Paramyxovirus
2. Incubation period: 10 to 20 days
3. Communicable period: From 4 days before to 5 days after rash appears, mainly during the prodromal stage (pertaining to early symptoms that may mark the onset of disease)
4. Source: Respiratory tract secretions, blood, or urine of infected person
5. Transmission: Airborne particles, direct contact with infectious droplets, or transplacental transmission

B. Assessment (Fig. 41.1)
1. Fever
2. Malaise
3. The 3 "Cs"—coryza, cough, conjunctivitis
4. Rash appears as red, erythematous maculopapular eruption starting on the face and spreading downward to the feet; blanches easily with pressure and gradually turns a brownish color (lasts 6 to 7 days); may have desquamation.
5. Koplik's spots: Small red spots with a bluish white center and a red base; located on the buccal mucosa and last 3 days

C. Interventions
1. Use airborne and contact precautions if the child is hospitalized.
2. Restrict child to quiet activities and bed rest.
3. Use a cool mist vaporizer for cough and coryza.
4. Dim lights if photophobia is present.
5. Administer antipyretics for fever.
6. Administer vitamin A supplementation as prescribed.

V. Roseola (Exanthema Subitum)

A. Description
1. Agent: Human herpesvirus type 6
2. Incubation period: 5 to 15 days
3. Communicable period: Unknown, but thought to extend from the febrile stage to the time the rash first appears

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

FIG. 41.1 Rubeola (measles). Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 185.

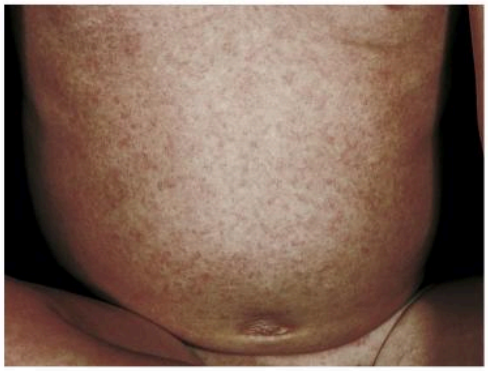

FIG. 41.2 Roseola (exanthema subitum). (From Habif, 2004.)

4. Source and transmission: Unknown; institute standard precautions and other precautions based on the child's symptoms.
5. Transmission: Unknown

B. Assessment (Fig. 41.2)
1. Sudden high (>38.8° C [> 102° F]) fever of 3 to 5 days' duration in a child who appears well, followed by a rash (rose-pink macules that blanch with pressure); febrile seizures may occur
2. Rash appears several hours to 2 days after the fever subsides and lasts 1 to 2 days.

C. Interventions: Supportive

VI. Rubella (German Measles)

A. Description
1. Agent: Rubella virus
2. Incubation period: 14 to 21 days
3. Communicable period: From 7 days before to about 5 days after rash appears
4. Source: Nasopharyngeal secretions; virus is also present in blood, stool, and urine.
5. Transmission
   a. Airborne or direct contact with infectious droplets
   b. Indirectly via articles freshly contaminated with nasopharyngeal secretions, feces, or urine
   c. Transplacental

FIG. 41.3 Rubella (German measles). (From Zitelli, Davis, 2007. Courtesy Dr. Michael Sherlock, Lutherville, MD.)

B. Assessment (Fig. 41.3)
1. Low-grade fever
2. Malaise
3. Pinkish red maculopapular rash that begins on the face and spreads to the entire body within 1 to 3 days
4. Petechiae (red, pinpoint spots) may occur on the soft palate.

C. Interventions
1. Use airborne, droplet, and contact precautions if the child is hospitalized; provide supportive treatment.
2. Isolate the infected child from pregnant persons.

VII. Mumps

A. Description
1. Agent: Paramyxovirus
2. Incubation period: 14 to 21 days
3. Communicable period: Immediately before and after parotid gland swelling begins
4. Source: Saliva of infected person and possibly urine
5. Transmission: Direct contact or droplet spread from an infected person

B. Assessment
1. Fever
2. Headache and malaise
3. Anorexia
4. Jaw or ear pain aggravated by chewing, followed by parotid glandular swelling
5. Orchitis or oophoritis may occur.
6. Deafness may occur.
7. Aseptic meningitis may occur (see Chapters 39 and 59 for information on meningitis).

C. Interventions (see Clinical Judgment: Generate Solutions Box)

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: GENERATE SOLUTIONS

A hospitalized 7-year-old child is diagnosed with mumps. The nurse would prepare for the following in the care of the child:

- Arrange for the child to be moved to a private room.
- Ensure that standard precautions and droplet and contact precautions are instituted.
- Ensure that all health care personnel in contact with the child wear an N95 respirator mask.
- Ensure that all health care personnel in contact with the child wear gowns and gloves and perform hand hygiene before and after client contact.
- Ensure that the child rests.
- Provide soft foods that will not require chewing to alleviate parotid gland discomfort.
- Apply hot or cold compresses to the neck to promote comfort.
- Apply warmth and local support with snug-fitting underpants to relieve orchitis.
- Monitor for signs of aseptic meningitis and report them to the primary health care provider if they occur.
- Instruct the parents in measures to prevent the transmission of the communicable disease.

VIII. Chicken Pox (Varicella)

A. Description
1. Agent: Varicella-zoster (VCZ) virus
2. Incubation period: 14 to 16 days
3. Communicable period: From 1 to 2 days before the onset of the rash to 6 days after the first crop of vesicles, when crusts have formed
4. Source: Respiratory tract secretions of infected person; skin lesions
5. Transmission: Direct contact, airborne, droplet spread, and contaminated objects

B. Assessment (Fig. 41.4)
1. Slight fever, malaise, and anorexia are followed by a macular rash that first appears on the trunk and scalp and moves to the face and extremities.
2. Lesions become pustules, begin to dry, and develop a crust.
3. Lesions may appear on the mucous membranes of the mouth, the genital area, and the rectal area.

C. Interventions
1. In the hospital, ensure strict isolation (airborne, droplet, and contact precautions).
2. At home, isolate the infected child until the vesicles have dried.
3. An antiviral agent may be used to treat varicella infections in susceptible immunocompromised persons to decrease the number of lesions; shorten the duration of fever; and decrease itching, lethargy, and anorexia.

FIG. 41.4 Chicken pox (varicella). (From Habif, 2004.)

4. The use of varicella zoster (VCZ) immune globulin or intravenous immune globulin (IVIG) is recommended for children who are immunocompromised, who have no previous history of varicella, and who are likely to contract the disease and have complications as a result.
5. Provide supportive care.

! Isolate high-risk children, such as children who have immunosuppressive disorders, from a child with a communicable disease.

IX. Pertussis (Whooping Cough)

A. Description
1. Agent: *Bordetella pertussis*
2. Incubation period: Average incubation is 7 to 10 days, but can range from 6 to 20 days
3. Communicable period: Greatest during the catarrhal stage (when discharge from respiratory secretions occurs)
4. Source: Discharge from the respiratory tract of the infected person
5. Transmission: Direct contact or droplet spread from infected person; indirect contact with freshly contaminated articles

B. Assessment
1. Symptoms of respiratory infection followed by increased severity of cough, with a loud whooping inspiration
2. May experience cyanosis, respiratory distress, and tongue protrusion
3. Listlessness, irritability, anorexia

C. Interventions
1. Isolate child during the catarrhal stage; if the child is hospitalized, institute droplet and contact precautions.
2. Administer antimicrobial therapy as prescribed.
3. Reduce environmental factors that cause coughing spasms, such as dust, smoke, and sudden changes in temperature.
4. Ensure adequate hydration and nutrition.
5. Provide suction and humidified oxygen if needed.
6. Monitor cardiopulmonary status (via monitor as prescribed) and pulse oximetry.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

7. Infants do not receive birthing parent immunity to pertussis; the tetanus–diphtheria–acellular pertussis (Tdap) vaccine would be administered to birth parent in the postpartum period and those in close contact with the infant to prevent the spread of pertussis to infants.

X. Diphtheria

A. Description
1. Agent: *Corynebacterium diphtheriae*
2. Incubation period: 2 to 5 days
3. Communicable period: Variable, until virulent bacilli are no longer present (three negative cultures of discharge from the nose and nasopharynx, skin, and other lesions); usually 2 weeks, but can be 4 weeks
4. Source: Discharge from the mucous membrane of the nose and nasopharynx, skin, and other lesions of the infected person
5. Transmission: Direct contact with infected person, carrier, or contaminated articles

B. Assessment
1. Low-grade fever, malaise, sore throat
2. Foul-smelling, mucopurulent nasal discharge
3. Dense pseudomembrane formation in the throat that may interfere with eating, drinking, and breathing
4. Lymphadenitis, neck edema, "bull neck"

C. Interventions
1. Ensure strict isolation for the hospitalized child.
2. Administer diphtheria antitoxin as prescribed (after a skin or conjunctival test to rule out sensitivity to horse serum).
3. Provide bed rest.
4. Administer antibiotics as prescribed.
5. Provide suction and humidified oxygen as needed.
6. Provide tracheostomy care if a tracheotomy is necessary.

XI. Poliomyelitis

A. Description
1. Agent: Enteroviruses
2. Incubation period: 7 to 14 days
3. Communicable period: Unknown; the virus is present in the throat and feces shortly after infection and persists for about 1 week in the throat and 4 to 6 weeks in the feces.
4. Source: Oropharyngeal secretions and feces of the infected person
5. Transmission: Direct contact with infected person; fecal-oral and oropharyngeal routes

B. Assessment
1. Fever, malaise, anorexia, nausea, headache, sore throat
2. Abdominal pain followed by soreness and stiffness of the trunk, neck, and limbs that may progress to central nervous system paralysis

C. Interventions
1. Enteric and contact precautions
2. Supportive treatment
3. Bed rest
4. Monitoring for respiratory paralysis
5. Physical therapy

XII. Scarlet Fever

A. Description
1. Agent: Group A β-hemolytic streptococci
2. Incubation period: 2 to 5 days, with a range of 1 to 7 days
3. Communicable period: About 10 days during the incubation period and clinical illness; during the first 2 weeks of the carrier stage, although may persist for months
4. Source: Nasopharyngeal secretions of infected person and carriers
5. Transmission: Direct contact with infected person or droplet spread; indirectly by contact with contaminated articles, ingestion of contaminated milk, or other foods

B. Assessment (Fig. 41.5)
1. Abrupt high fever, flushed cheeks, vomiting, headache, enlarged lymph nodes in the neck, malaise, abdominal pain
2. A red, fine sandpaper–like rash develops in the axilla, groin, and neck, and spreads to cover the entire body except the face.
3. Rash blanches with pressure; pink or red lines of petechiae are noted in areas of deep creases and folds of the joints (Pastia's sign).
4. Desquamation, sheetlike sloughing of the skin on palms and soles, appears by weeks 1 to 3.
5. The tongue is initially coated with a white, furry covering with red projecting papillae (white strawberry tongue); by the third to fifth day, the white coat sloughs off, leaving a red swollen tongue (red strawberry tongue).
6. Tonsils are reddened, edematous, and covered with exudate.
7. Pharynx is edematous and beefy red.

C. Interventions
1. Institute contact and droplet precautions until 24 hours after initiation of antibiotics.
2. Provide supportive therapy.
3. Provide bed rest.
4. Encourage fluid intake.

XIII. Erythema Infectiosum (Fifth Disease)

A. Description
1. Agent: Human parvovirus B19
2. Incubation period: 4 to 14 days; may be 20 days
3. Communicable period: Uncertain but before the onset of symptoms in most children
4. Source: Infected person
5. Transmission: Unknown; possibly respiratory secretions and blood

Telegram & Insta: NCLEX_RN_Edu

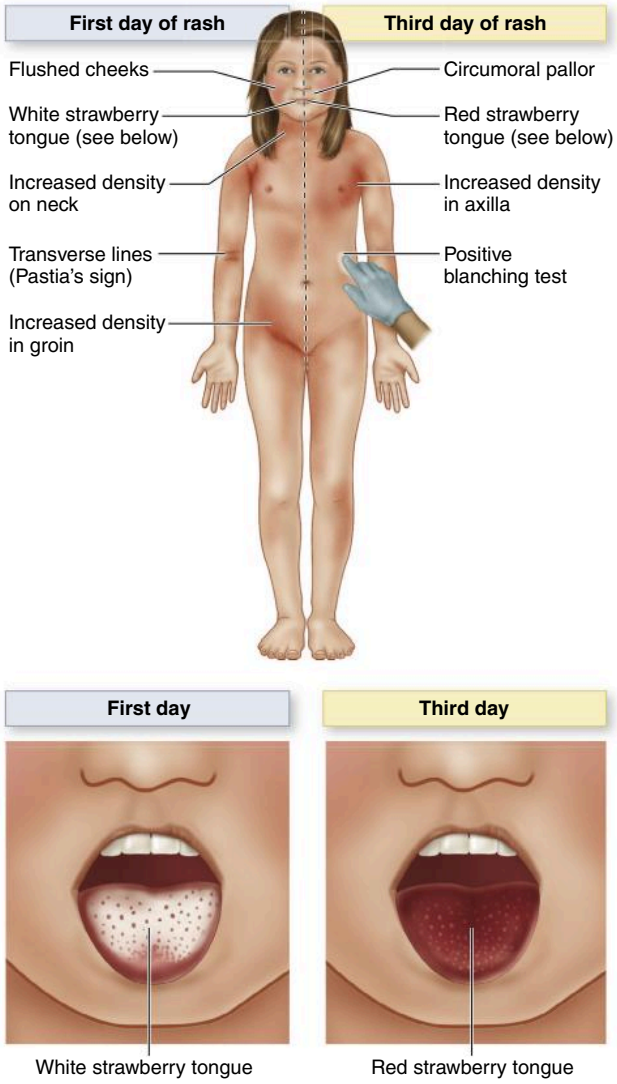

FIG. 41.5 Scarlet fever.

B. Assessment
1. Before rash: Asymptomatic or mild fever, malaise, headache, runny nose
2. Stages of rash
   - **a.** Erythema of the face (slapped-cheek appearance) develops and disappears by 1 to 4 days (Fig. 41.6).
   - **b.** About 1 day after the rash appears on the face, maculopapular red spots appear, symmetrically distributed on the extremities; the rash progresses from proximal to distal surfaces and may last a week or more.
   - **c.** The rash subsides but may reappear if the skin becomes irritated by the sun, heat, cold, exercise, or friction.

C. Interventions
1. Child is not usually hospitalized.
2. Administer antipyretics, analgesics, and antiinflammatory medications as prescribed.
3. Provide supportive care.

FIG. 41.6 Erythema infectiosum (fifth disease): Slapped-face appearance. (From Habif, 2004.)

⚠ Pregnant persons need to contact their primary health care provider if they come in contact with a child with a communicable disease.

XIV. Infectious Mononucleosis

A. Description
1. Agent: Epstein-Barr virus
2. Incubation period: 4 to 6 weeks
3. Communicable period: Unknown
4. Source: Oral secretions, blood transfusions, or transplantation
5. Transmission: Direct intimate contact

B. Assessment
1. Fever, malaise, headache, fatigue, nausea, abdominal pain, sore throat, enlarged red tonsils
2. Lymphadenopathy and hepatosplenomegaly
3. Discrete macular rash most prominent over the trunk may occur.

C. Interventions
1. Provide supportive care.
2. Monitor for signs of splenic rupture.

⚠ Teach the parents of a child with mononucleosis to monitor for signs of splenic rupture, which include abdominal pain, left upper quadrant pain, and left shoulder pain.

XV. Rocky Mountain Spotted Fever

A. Description
1. Agent: *Rickettsia rickettsii*
2. Incubation period: 2 to 14 days
3. Source: Tick from a mammal, most often from wild rodents and dogs
4. Transmission: Bite of infected tick

B. Assessment
1. Fever, malaise, anorexia, vomiting, headache, myalgia
2. Maculopapular or petechial rash primarily on the extremities (ankles and wrists), but may spread to other areas, characteristically on the palms and soles

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 41.3 Measures to Protect Children from Tick Bites

- Wearing long-sleeved shirts, long pants tucked into long socks (socks need to be pulled up over the pant legs), and a hat when walking in tick-infested areas
- Wearing light-colored clothing to make ticks more visible if they get onto the child
- Checking children for the presence of ticks after being in high-risk or tick-infested areas
- Following paths rather than walking in tall grass and shrub areas, because these are the places where most ticks are found
- Applying insect repellents containing diethyltoluamide (DEET) and permethrin before possible exposure to areas where ticks are found (use with caution in infants and small children)
- Keeping yards at home trimmed and free of accumulating leaves and other brush
- Applying tick repellent to dogs
- Saving the tick for later identification if it is removed from the child's body
- To remove the tick, grasp the tick at the point of closest contact to the skin with tweezers and pull straight up with steady, even pressure; remove any remaining parts with a sterile needle; if using bare hands, use a tissue during removal; wash hands with soap and water.

C. Interventions
1. Provide vigorous supportive care.
2. Administer antibiotics as prescribed.
3. Teach the child and parents about protection from tick bites (Box 41.3).

XVI. Community-Associated Methicillin-Resistant *Staphylococcus aureus* (CA-MRSA)

A. Description (also see Chapter 13)
1. *Staphylococcus aureus* is a bacterium that is normally located on the skin or in the nose of healthy people; when present without symptoms, it is called *colonization*, and when symptoms are present, it is called an *infection*.
2. MRSA is a strain of *S. aureus* that is resistant to methicillin and most often occurs in people who were hospitalized or treated at a health care facility (hospital-acquired MRSA).
3. CA-MRSA is a MRSA infection that occurs in a healthy person who has not been hospitalized or had a medical procedure done within the past year.
4. Persons at risk for CA-MRSA include athletes, prisoners, day care attendees, military recruits, persons who abuse intravenous drugs, persons living in crowded settings, persons with poor hygiene practices, persons who use contaminated items, persons who get tattoos, and persons with a compromised immune system.
5. CA-MRSA is spread through person-to-person contact, through contact with contaminated items, or through infection of a preexisting cut or wound that is not protected by a dressing.
6. The bacteria can enter the bloodstream through the cut or wound and cause sepsis, cellulitis, endocarditis, osteomyelitis, septic arthritis, toxic shock syndrome, pneumonia, organ failure, and death.

B. Prevention measures
1. Frequent handwashing and strict aseptic technique in health care facilities
2. Handwashing and practicing good personal hygiene
3. Avoiding the sharing of personal items
4. Regular cleaning of shared equipment, such as athletic equipment, whirlpools, or saunas
5. Cleaning a cut or wound thoroughly
6. Ensuring that tattoo or body piercing facilities adhere to strict guidelines regarding infection prevention

C. Assessment
1. Appearance of a skin infection: Red, swollen area; warmth around the area; drainage of pus; pain at the site; fever
2. Symptoms of a more serious infection: Chest pain, cough, fatigue, chills, fever, malaise, headache, muscle aches, shortness of breath, rash

D. Interventions
1. Assess skin lesions.
2. Prepare to drain an infected skin site and culture the wound and wound drainage.
3. Prepare to obtain blood cultures, sputum cultures, and urine cultures.
4. Prepare to administer antibiotics as prescribed.
5. Educate the child and family about the causes and modes of transmission, signs and symptoms, and importance of treatment measures prescribed.

XVII. Influenza

A. Description
1. Various strains of influenza can occur.
2. It is a viral infection that affects the respiratory system and is highly contagious.
3. Children, pregnant persons, persons with preexisting health conditions, and persons with a compromised immune system are at high risk for developing complications.
4. It is caused by contact with an infected person or by touching something such as a toy or tissue that the infected person has touched.

B. Prevention
1. Flu vaccine
2. Wash the child's hands frequently and teach handwashing techniques.
3. Avoid children who are ill.

Telegram & Insta: NCLEX_RN_Edu

4. Keep the child home from school or away from others until the child has been fever-free (without the use of antipyretics) for at least 24 hours.

The signs and symptoms of flu usually last a week. If they last longer, the presence of complications needs to be suspected.

C. Assessment
   1. Fever that occurs suddenly and is high
   2. Headache, body aches, fatigue, chills, cough, congestion, sore throat, loss of appetite, vomiting, diarrhea

D. Interventions
   1. Antiviral medications if prescribed, fluids, rest, pain relievers such as acetaminophen or ibuprofen
   2. Family and child teaching about prevention measures

XVIII. COVID-19 (Coronavirus)

A. SARS-CoV-2 is the coronavirus that causes COVID-19.
B. At the current time, noted is that the virus usually causes milder symptoms in babies and children than in adults.
C. As with adults, existing underlying conditions such as asthma or diabetes mellitus place the child at greater risk for more severe symptoms. Parents should be taught to seek immediate medical care if the child experiences difficulty breathing, vomiting and the inability to hold in fluids, confusion, inability to arouse, or cyanosis.
D. Transmission is via contact with the virus via respiratory droplets; droplet and airborne precautions and contact precautions are necessary.
E. The most common symptoms are fever and cough; children can also experience sore throat, excessive fatigue, or diarrhea.
F. Prevention includes avoiding crowds; maintaining 6 feet of social distancing, especially from sick people; handwashing; the use of hand sanitizer; wearing masks; coughing and sneezing into the elbow; keeping the hands away from the face; and keeping things clean, such as toys or surfaces frequently touched.
G. A concern is the development of pediatric inflammatory multisystem syndrome (PIMS). Although this is a rare condition, it is thought that it might be related to exposure to the coronavirus.
H. PIMS can cause inflammation of the blood vessels throughout the body, and this inflammation can limit blood flow, damaging the heart and other organs. It has characteristics similar to toxic shock syndrome and Kawasaki disease (see Chapter 37 for information on Kawasaki disease).
I. Symptoms of PIMS include fever, abdominal pain, vomiting, diarrhea, red rash, red cracked lips, red eyes, swollen glands in the neck, and swollen hands and feet. From: Milstone, A. (2020). Coronavirus in babies and kids. *Health.* The Johns Hopkins University, https://www.hopkinsmedicine.org/health/conditions-and-diseases/coronavirus/coronavirus-in-babies-and-children
J. For the latest updates, refer to the Centers for Disease Control and Prevention (CDC), COVID-19 in children and teens at https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/children/symptoms.html

XIX. Immunizations

1. For immunization schedules and guidelines refer to Chapter 19.
2. For additional information, refer to the Centers for Disease Control and Prevention (CDC) website: https://www.cdc.gov/vaccines/schedules/hcp/imz/child-adolescent.html

PRACTICE QUESTIONS

1. An infant of a birth parent infected with human immunodeficiency virus (HIV) is seen in the clinic each month and is being monitored for symptoms indicative of HIV infection. With knowledge of the **most** common opportunistic infection of children infected with HIV, the nurse assesses the infant for which sign?
   1. Cough
   2. Liver failure
   3. Watery stool
   4. Nuchal rigidity

2. The nurse provides home care instructions to the parent of a child with acquired immunodeficiency syndrome (AIDS). Which statement by the parent indicates the **need for further teaching**?
   1. "I will wash my hands frequently."
   2. "I will keep my child's immunizations up to date."
   3. "I will avoid direct unprotected contact with my child's body fluids."
   4. "I can send my child to day care with a fever as long as it is a low-grade fever."

3. The clinic nurse is instructing the parent of a child with human immunodeficiency virus (HIV) infection regarding immunizations. The nurse would provide which instruction to the parent?
   1. The hepatitis B vaccine will not be given to the child.
   2. The inactivated influenza vaccine will be given yearly.
   3. The varicella vaccine will be given before 6 months of age.
   4. A Western blot test needs to be performed and the results evaluated before immunizations.

Telegram & Insta: NCLEX_RN_Edu

4. A pediatrician prescribes laboratory studies for the infant of a birthing parent positive for human immunodeficiency virus (HIV). The nurse anticipates that which laboratory study will be prescribed for the infant?
   1. Chest x-ray
   2. Western blot
   3. $CD4^+$ cell count
   4. p24 antigen assay

5. A birthing parent with human immunodeficiency virus (HIV) infection brings a 10-month-old infant to the clinic for a routine checkup. The pediatrician has documented that the infant is asymptomatic for HIV infection. After the checkup the parent tells the nurse about being so pleased that the infant will not get HIV infection. The nurse would make which **most appropriate** response to the parent?
   1. "I am so pleased also that everything has turned out fine."
   2. "Because symptoms have not developed, it is unlikely that your infant will develop HIV infection."
   3. "Everything looks great, but be sure to return with your infant next month for the scheduled visit."
   4. "Most children infected with HIV develop symptoms within the first 9 months of life, and some become symptomatic sometime before they are 3 years old."

6. A 6-year-old child with human immunodeficiency virus (HIV) infection has been admitted to the hospital for pain management. The child asks the nurse if the pain will ever go away. The nurse would make which **best** response to the child?
   1. "The pain will go away if you lie still and let the medicine work."
   2. "Try not to think about it. The more you think it hurts, the more it will hurt."
   3. "I know it must hurt, but if you tell me when it does, I will try to make it hurt a little less."
   4. "Every time it hurts, press on the call button and I will give you something to make the pain go all away."

7. The home care nurse provides instructions regarding basic infection control to the parent of an infant with human immunodeficiency virus (HIV) infection. Which statement, if made by the parent, indicates the **need for further instruction**?
   1. "I will clean up any spills from the diaper with diluted alcohol."
   2. "I will wash baby bottles, nipples, and pacifiers in the dishwasher."
   3. "I will be sure to prepare foods that are high in calories and high in protein."
   4. "I will be sure to wash my hands carefully before and after caring for my infant."

8. Which home care instructions would the nurse provide to the parent of a child with acquired immunodeficiency syndrome (AIDS)? **Select all that apply.**
   - ❑ 1. Monitor the child's weight.
   - ❑ 2. Frequent handwashing is important.
   - ❑ 3. The child needs to avoid exposure to other illnesses.
   - ❑ 4. The child's immunization schedule will need revision.
   - ❑ 5. Clean up body fluid spills with bleach solution (10:1 ratio of water to bleach).
   - ❑ 6. Fever, malaise, fatigue, weight loss, vomiting, and diarrhea are expected to occur and do not require special intervention.

9. The nurse provides home care instructions to the parents of a child hospitalized with pertussis who is in the convalescent stage and is being prepared for discharge. Which statement by a parent indicates a **need for further instruction**?
   1. "We need to encourage our child to drink fluids."
   2. "Coughing spells may be triggered by dust or smoke."
   3. "Vomiting may occur when our child has coughing episodes."
   4. "We need to maintain droplet precautions and a quiet environment for at least 2 weeks."

10. The nurse caring for a child diagnosed with rubeola (measles) notes that the pediatrician has documented the presence of Koplik's spots. On the basis of this documentation, which observation is expected?
    1. Pinpoint petechiae noted on both legs
    2. Whitish vesicles located across the chest
    3. Petechiae spots that are reddish and pinpoint on the soft palate
    4. Small blue-white spots with a red base found on the buccal mucosa

11. The parent of a child with mumps calls the health care clinic to tell the nurse that the child has been lethargic and vomiting. What instruction would the nurse give to the parent?
    1. To continue to monitor the child
    2. That lethargy and vomiting are normal with mumps
    3. To bring the child to the clinic to be seen by the pediatrician
    4. That there is nothing to be concerned about as long as there is no fever

Telegram & Insta: NCLEX_RN_Edu

12. The nurse is assessing a child admitted with a diagnosis of rheumatic fever. Which significant question would the nurse ask the child's parent during the assessment?
1. "Has your child had difficulty urinating?"
2. "Has your child been exposed to anyone with chicken pox?"
3. "Has any family member had a sore throat within the past few weeks?"
4. "Has any family member had a gastrointestinal disorder in the past few weeks?"

13. The nurse is caring for a child diagnosed with erythema infectiosum (fifth disease). Which clinical manifestation would the nurse expect to note in the child?
1. An intense fiery red edematous rash on the cheeks
2. Pinkish-rose maculopapular rash on the face, neck, and scalp
3. Reddish and pinpoint petechiae spots found on the soft palate
4. Small bluish-white spots with a red base found on the buccal mucosa

ANSWERS

1. *Answer:* 1
Rationale: Acquired immunodeficiency syndrome (AIDS) is a disorder caused by HIV and characterized by generalized dysfunction of the immune system. The most common opportunistic infection of children infected with HIV is *Pneumocystis jiroveci* pneumonia, which occurs most frequently between the ages of 3 and 6 months, when HIV status may be indeterminate. Cough is a common sign of this opportunistic infection. Cytomegalovirus infection is also characteristic of HIV infection; however, it is not the most common opportunistic infection. Liver failure is a common sign of this complication. Although gastrointestinal disturbances and neurological abnormalities may occur in a child with HIV infection, options 3 and 4 are not specific opportunistic infections noted in the HIV-infected child. Watery stool is noted with gastroenteritis, and nuchal rigidity is seen in meningitis.
Test-Taking Strategy: Note the **strategic word,** *most*. This will direct you to the correct option. Also use of the **ABCs—airway breathing, and circulation**—will assist in answering correctly. Remember that the most common opportunistic infection of children infected with HIV is *P. jiroveci* pneumonia and that cough is a common sign with this complication.
References: Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology.* (7th ed.). St. Louis: Elsevier. p. 705; Murray, S., McKinney, E., Holub, K., & Jones, R. (2019). *Foundations of maternal-newborn and women's health nursing.* (7th ed.). St. Louis: Elsevier. p. 262.

2. *Answer:* 4
Rationale: AIDS is a disorder caused by human immunodeficiency virus (HIV) and characterized by generalized dysfunction of the immune system. A child with AIDS who is sick or has a fever needs to be kept home and not brought to a day care center. Options 1, 2, and 3 are correct statements and would be actions a caregiver needs to take when the child has AIDS.
Test-Taking Strategy: Note the **strategic words,** *need for further teaching*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Noting the word *fever* in the correct option will direct you to this option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1064.

3. *Answer:* 2
Rationale: Immunizations against common childhood illnesses are recommended for all children exposed to or infected with HIV. The inactivated influenza vaccine that is given intramuscularly will be administered (influenza vaccine would be given yearly). The hepatitis B vaccine is administered according to the recommended immunization schedule. Varicella-zoster virus vaccine would not be given, because it is a live virus vaccine; varicella-zoster immunoglobulin may be prescribed after exposure to chicken pox. Option 4 is unnecessary and inaccurate.
Test-Taking Strategy: Focus on the **subject,** immunizations for the child with HIV. Option 4 can be eliminated first because the Western blot is a diagnostic test, not an evaluative test. From the remaining options, recalling that the child infected with HIV is at risk for opportunistic infections and that live virus vaccines are not administered to an immunodeficient child will assist in directing you to the correct option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1063.

4. *Answer:* 4
Rationale: Infants born to HIV-infected mothers need to be screened for the HIV antigen. The detection of HIV in infants is confirmed by a p24 antigen assay, virus culture of HIV, or polymerase chain reaction. A Western blot test confirms the presence of HIV antibodies. The $CD4^+$ cell count indicates how well the immune system is working. A chest x-ray evaluates the presence of other manifestations of HIV infection, such as pneumonia.
Test-Taking Strategy: Focus on the **subject,** laboratory tests for the infant of a birthing parent positive for HIV. Be sure to note the word *infant*. Recall the laboratory tests used to determine the presence of HIV infection in the infant to answer this question.
References: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 1062; Murray, S., McKinney, E., Holub, K., & Jones, R. (2019). *Foundations of maternal-newborn and women's health nursing.* (7th ed.). St. Louis: Elsevier. p. 262.

Telegram & Insta: NCLEX_RN_Edu

5. *Answer:* 4
Rationale: Acquired immunodeficiency syndrome (AIDS) is caused by HIV infection and characterized by generalized dysfunction of the immune system. Most children infected with HIV develop symptoms within the first 9 months of life. The remaining infected children become symptomatic sometime before age 3 years. With their immature immune systems, children have a much shorter incubation period than adults. Options 1, 2, and 3 are incorrect. Additionally, these options offer false reassurance.
Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Eliminate options 1, 2, and 3 because they are **comparable or alike** in content. The correct option is the only one that provides specific and accurate data regarding HIV infection in an infant.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1061-1063.

6. *Answer:* 3
Rationale: The multiple complications associated with HIV are accompanied by a high level of pain. Aggressive pain management is essential for the child to have an acceptable quality of life. The nurse must acknowledge the child's pain and let the child know that everything will be done to decrease the pain. Telling the child that movement or lack thereof would eliminate the pain is inaccurate. Allowing children to think that they can control pain simply by thinking or not thinking about it oversimplifies the pain cycle associated with HIV. Giving false hope by telling the child that the pain will be taken "all away" is neither truthful nor realistic.
Test-Taking Strategy: Note the **strategic word,** *best.* Recall the general concept of pain and the growth and development concepts of a 6-year-old child. Remembering to give children information about pain in words that they can understand, but without providing false hope or being less than truthful, would guide you to the correct option. Options 1 and 2 provide inaccurate information about pain management. Option 4 provides false hope that the pain can be alleviated completely.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1062-1064.

7. *Answer:* 1
Rationale: HIV is transmitted through blood, semen, vaginal secretions, and human milk. The birthing parent of an infant with HIV would be instructed to use a bleach solution for disinfecting contaminated objects or cleaning up spills from the child's diaper. Alcohol would not be effective in destroying the virus. Options 2, 3, and 4 are accurate instructions related to basic infection control.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Recalling basic infection control measures and the measures to prevent the spread of HIV will direct you to the correct option.
Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 435, 436, 438.

8. *Answer:* 1, 2, 3, 5
Rationale: AIDS is a disorder caused by human immunodeficiency virus (HIV) infection and is characterized by a generalized dysfunction of the immune system. Home care instructions include the following: frequent handwashing; monitoring for fever, malaise, fatigue, weight loss, vomiting, and diarrhea and notifying the pediatrician if these occur; monitoring for signs and symptoms of opportunistic infections; administering antiretroviral medications and other medications as prescribed; avoiding exposure to other illnesses; keeping immunizations up to date; monitoring weight and providing a high-calorie, high-protein diet; washing eating utensils in the dishwasher; and avoiding the sharing of eating utensils. Gloves are worn for care, especially when in contact with body fluids and changing diapers; diapers are changed frequently and away from food areas, and soiled disposable diapers are folded inward, closed with the tabs, and disposed of in a tightly covered plastic-lined container. Any body fluid spills are cleaned with a bleach solution (10:1 ratio of water to bleach).
Test-Taking Strategy: Focus on the **subject,** care of the child with AIDS. Recalling that AIDS is characterized by a generalized dysfunction of the immune system and recalling the modes of transmission of the virus will assist in selecting the correct home care instructions.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 1062-1064.

9. *Answer:* 4
Rationale: Pertussis is transmitted by direct contact or respiratory droplets from coughing. The communicable period occurs primarily during the catarrhal stage. Respiratory precautions are not required during the convalescent phase. Options 1, 2, and 3 are accurate components of home care instructions.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Also, note the word *convalescent* in the question. Options 1 and 3 can be eliminated because they are generally associated with convalescence. Knowing that 2 weeks of respiratory precautions is not required during the convalescent period will direct you to this option.
Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 182, 187.

10. *Answer:* 4
Rationale: In rubeola (measles), Koplik's spots appear approximately 2 days before the appearance of the rash. These are small blue-white spots with a red base that are found on the buccal mucosa. The spots last approximately 3 days, after which time they slough off. Based on this information, the remaining options are all incorrect.
Test-Taking Strategy: Eliminate options 1 and 3, which are **comparable or alike** and address petechiae spots. Focusing on the **subject,** Koplik's spots, will direct you to the correct option.

Telegram & Insta: NCLEX_RN_Edu

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 182.

11. *Answer:* 3

Rationale: Mumps generally affects the salivary glands, but it can also affect multiple organs. The most common complication is septic meningitis, with the virus being identified in the cerebrospinal fluid. Common signs include nuchal rigidity, lethargy, and vomiting. The child needs to be seen by the pediatrician.

Test-Taking Strategy: Focus on the **subject,** a child with mumps who has been lethargic and vomiting. Recalling that meningitis is a complication of mumps will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 174, 181.

12. *Answer:* 3

Rationale: Rheumatic fever characteristically presents 2 to 6 weeks after an untreated or partially treated group A beta-hemolytic streptococcal infection of the respiratory tract. Initially the nurse determines whether any family member has had a sore throat or unexplained fever within the past few weeks. The remaining options are unrelated to the assessment findings of rheumatic fever.

Test-Taking Strategy: Focus on the **subject,** rheumatic fever. Note the word *significant.* Recalling that rheumatic fever characteristically presents 2 to 6 weeks after a streptococcal infection of the respiratory tract will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 996-997.

13. *Answer:* 1

Rationale: Fifth disease is characterized by the presence of an intense fiery red edematous rash on the cheeks, which gives an appearance that the child has been slapped. Options 2 and 3 are manifestations related to rubella (German measles). Koplik's spots (option 4) are found in rubeola (measles).

Test-Taking Strategy: Focus on the **subject,** erythema infectiosum (fifth disease). Recalling the "slapped cheek" appearance associated with fifth disease will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 181.

CHAPTER 42

Pediatric Medication Administration and Calculations

Contributor: Necole Leland, DNP, RN, PNP, CPN

PRIORITY CONCEPTS Development; Safety

I. Oral Medications (Clinical Judgment: Generate Solutions Box)

A. Most oral pediatric medications are in liquid or suspension form or chewable tablet form, because children usually are unable to swallow a tablet or capsule.

B. Solutions may be measured by using an oral plastic syringe or other acceptable measurement or administration device; the device used depends on the **developmental age** of the child (Fig. 42.1).

C. Medications in suspension settle to the bottom of the bottle between uses, and thorough mixing is required before pouring the medication.

D. Suspensions must be administered immediately after measurement to prevent settling and resultant administration of an incomplete dose.

E. Administer oral medications with a child sitting in an upright position and with the head elevated to prevent aspiration if the child cries or resists.

F. Place a small child sideways on the lap; the child's closest arm would be placed under the adult's arm and behind the adult's back; cradle the child's head, hold the child's hand, and administer the medication slowly with a plastic spoon, small plastic cup, or syringe.

G. If a tablet or capsule has been administered, check the child's mouth to ensure that it has been swallowed; if swallowing is a problem, some tablets can be crushed and given in small amounts of puréed food or flavored syrup (enteric-coated tablets, timed-release tablets, and capsules would not be crushed).

H. Follow generally accepted medication administration guidelines for children (Box 42.1).

Newborns and infants have an immature liver and immature kidneys; therefore, metabolism and elimination of medications is delayed.

CLINICAL JUDGMENT: GENERATE SOLUTIONS

The nurse is preparing to administer a medication that has an unpleasant taste to a hospitalized infant. To minimize this unpleasant effect, the nurse plans to administer the medication with the following method:

- Draw the required dose into a syringe without the needle.
- Place the infant sideways on the lap, placing the infant's closest arm under the nurse's arm and behind the nurse's back; cradle the infant's head, and hold the infant's hand.
- Place the syringe into the side and toward the back of the infant's mouth.
- Administer the medication slowly, allowing the infant to swallow.

II. Parenteral Medications

A. Subcutaneously and intramuscularly administered medications

1. Medications most often given via the subcutaneous route are insulin and some immunizations.

2. Any site with sufficient subcutaneous tissue may be used for subcutaneous injections; common sites include the central third of the lateral aspect of the upper arm, the abdomen, and the central third of the anterior thigh.

3. The safe use of injection sites is based on normal muscle development and the size of the child;

FIG. 42.1 Acceptable devices for measuring and administering oral medication to children *(clockwise from bottom left):* Measuring spoon, plastic syringes, calibrated nipple, plastic medicine cup, calibrated dropper, hollow-handled medicine spoon. (From Hockenberry, Wilson, 2005.)

BOX 42.1 Medication Administration Guidelines for Children

- Two identifiers are required before medication administration—such as name, medical record number, and birth date. Bar code scanning systems are commonly used as an additional safeguard to ensure that medications are given to the correct client.
- Obtain information from parents about successful methods for administering medications to their children.
- Ask parents about any known allergies.
- To avoid aspiration, liquid forms of medication are safer to swallow than other forms.
- Straws often help older children to swallow pills.
- Avoid putting medications in foods, such as cereal, baby food, or milk or formula, because it may cause an unpleasant taste to the food, and the child may refuse to accept the same food in the future. In addition, the child may not consume the entire serving and would not receive the required medication dosage.
- If the taste of the medication is unpleasant, it is acceptable to have the child pinch the nose and drink the medication through a straw.
- Offer juice, a soft drink, or a frozen juice bar after the child swallows a medication.
- Always read the pharmacological indications for administration. Some items such as fruit syrups can be acidic and would not be used with medications that react negatively in an acid medium.
- Record the most successful method of administering medications and pertinent nursing prescriptions on the child's care plan for other nursing staff to follow; this notation also saves the child frustration, fear, and anxiety.

Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 708-710; Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing*. (10th ed.). St. Louis: Elsevier. pp. 601, 606.

TABLE 42.1 Intramuscular Injection Sites by Muscle Group and Amounts in mL

Muscle	Infant	Child
Vastus lateralis	0.5	0.5-2
Ventrogluteal	0.5	0.5-2
Deltoid	Not recommended	0.5-1

Data from Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children*. (11th ed.). St. Louis: Elsevier. p. 711.

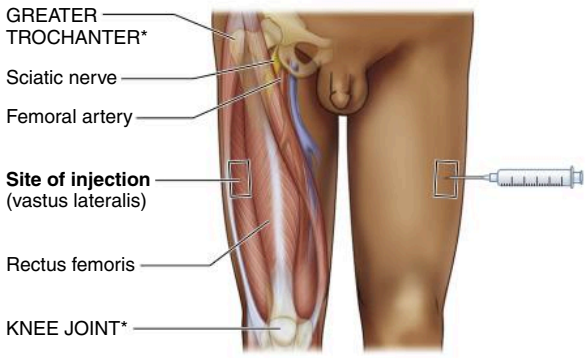

FIG. 42.2 Intramuscular injection site—vastus lateralis. Landmarks are indicated by asterisks.

the preferred site for intramuscular injections in infants is the vastus lateralis, but agency policies and procedures need to be followed (Table 42.1 and Fig. 42.2).

4. The usual needle length and gauge for pediatric clients are ⅝ to 1 inch (depending on age and site for administration) and 22 to 25 gauge; needle length also can be estimated by grasping the muscle between the thumb and forefinger—half the resulting distance would be the needle length.
5. Pediatric dosages for subcutaneous and intramuscular administration are calculated to the nearest hundredth and measured by using a tuberculin syringe; always follow agency guidelines.
6. Place a plain or decorated adhesive bandage over the puncture site to help the child view the experience in a pleasant way.

B. Intravenously administered medications

1. Intravenous (IV) medications are diluted for administration.
2. When an infant or child is receiving an IV medication, the IV site needs to be assessed for signs of inflammation and infiltration or extravasation immediately before, during, and after completion of each medication.
3. IV medications may be prescribed in a manner that requires a continuous infusion through a primary infusion line.

Telegram & Insta: NCLEX_RN_Edu

4. IV medications may be prescribed intermittently; several doses may be administered in a 24-hour period.
5. Medications for IV administration are diluted according to the directions accompanying the medication and according to the pediatrician's prescriptions and agency procedures.
6. Infusion time for IV medications is determined on the basis of the directions accompanying the medication, the pediatrician's prescription, and agency procedures.
7. Determine agency procedures related to the volume of flush (normal saline) for peripheral IV lines and for central lines.
8. The flush volume (3 to 20 mL) must be included in the child's intake; the flush is usually administered before administering an IV medication and after the IV medication is completed and is infused at the same rate as the medication.

C. Intermittent IV medication administration
1. Children receiving IV medications intermittently may or may not have a primary IV solution infusing.
2. If a primary IV solution is infusing, the medication may be administered by IV piggyback via a secondary line and via an infusion pump or infusion syringe device.
3. If a primary IV solution does not exist, an indwelling infusion catheter is used for medication administration, and the medication may be administered by push or piggyback; medication administration instructions must be checked for dilution and infusion time procedures.
4. All intermittent medication administrations are preceded and followed by a normal saline flush to ensure that the medication has cleared the IV tubing and that the total dose has been administered.
5. Electronic devices such as controllers or pumps are always used to regulate and administer IV fluids and intermittent IV medications.

D. Special IV administration sets
1. Special IV administration sets, such as a burette, may be used for medication preparation and administration via piggyback.
2. These special sets are all microdrip sets calibrated to deliver 60 drops (gtt)/mL.
3. The total capacity of these types of IV administration sets is 100 to 150 mL, calibrated in 1-mL increments so that exact measurements of small volumes are possible.
4. The medication is mixed with the appropriate amount of diluent, added to the IV administration set, and allowed to infuse at the prescribed rate.
5. The IV administration set needs to be labeled clearly to identify the medication and fluid dosage added.
6. During medication infusion time, a label (per agency guidelines) is attached that indicates that the medication is infusing.
7. During the flush infusion time, a label (per agency guidelines) is attached indicating that the flush is infusing.

E. Syringe pump for IV medication administration
1. A syringe containing the medication is fitted into a pump that is connected to the IV tubing through a Y connector.
2. The medication is administered over the prescribed time.

The 24-hour fluid intake must be monitored closely, and all IV fluid amounts, including the amount of flush volume, need to be documented accurately to prevent overhydration. For children, the maximum amount of IV fluid administered in a 24-hour period varies and is usually based on body weight and other factors. Check the prescription and agency guidelines for the procedures for the administration of IV fluids and medications.

III. Calculation of Medication Dosage by Body Weight

A. Conversion of body weight
1. There are many mobile application devices available to assist with calculating dosages, but it is important to know how to do these calculations without the use of a mobile device.
2. See Box 42.2 for body weight conversion.

B. Calculation of daily dosages based on weight
1. Abbreviations (Box 42.3)
2. Dosages are expressed in terms of milligrams per kilogram per day, milligrams per pound per day, or milligrams per kilogram per dose.
3. The total daily dosage usually is administered in divided (more than one) doses per day as prescribed.
4. Express the child's body weight in kilograms or pounds to correlate with the dosage specifications.
5. Calculate the total daily dosage.
6. Divide the total daily dosage by the number of doses to be administered in 1 day.
7. Always double-check the dosage calculation to make sure the dose being administered is safe, based on the weight of the child (Box 42.4).

IV. Medication Calculation Based on Body Surface Area (BSA)

A. When dosage recommendations for children specify milligrams, micrograms, or units per square meter, calculating the dosage is simple multiplication (Box 42.5).

Telegram & Insta: NCLEX_RN_Edu

BOX 42.2 Conversion of Body Weight

Measurements:

$1\ lb = 16\ oz$

$2.2\ lb = 1\ kg$

Pounds to Kilograms:

$2.2\ lb = 1\ kg$

When converting from pounds to kilograms, divide by 2.2. Kilograms are expressed to the nearest tenth.

Kilograms to Pounds:

$1\ kg = 2.2\ lb$

When converting from kilograms to pounds, multiply by 2.2. Pounds are expressed to the nearest tenth.

BOX 42.3 Common Measurement Abbreviations

Abbreviation	Meaning
BSA	Body surface area
g	Gram(s)
gr	Grain(s)
kg	Kilogram(s)
lb	Pound(s)
m^2	Square meters
mcg	Microgram(s)
mg	Milligram(s)
mL	Milliliter(s)
SA	Surface area

B. When dosage recommendations are specified only for adults, a formula is used to calculate a child's dosage from the adult dosage (Box 42.6).

V. Developmental Considerations for Administering Medications

A. When administering medications to children, developmental age must be taken into consideration to ensure safe and effective administration.

B. General interventions

1. Always be prepared for the procedure with all necessary equipment and assistance.
2. For a hospitalized child, ask the parent or child or both as appropriate if the parent would or would not like to remain present for the procedure.
3. Determine appropriate preadministration and postadministration comfort measures.
4. Try to make the event as pleasant as possible.

C. Box 42.7 lists developmental considerations when giving medications.

BOX 42.4 Calculation of a Safe Dose by Weight

Example 1:

Ceftriaxone 500 mg IV daily is prescribed. The child weighs 15 lb. Per pharmacy, the safe dose is 50 to 75 mg/kg/dose. Is the prescribed dose safe for the child?

$15\ lb \div 2.2\ kg = 6.8\ kg$

$6.8kg \times 50mg = 340mg/dose$

$6.8kg \times 75\ mg = 510\ mg/dose$

Answer: The prescribed dose of 500 mg IV daily is safe for the child.

Example 2:

The child has a prescription for ampicillin 850 mg IV every 6 hours. The child weighs 36 lb. Per pharmacy, the safe dose is 50 mg/kg/dose IV every 6 hours. Is the prescribed dose safe for the child?

$36\ lb \div 2.2\ kg = 16.4\ kg$

$16.4\ kg \times 50\ mg = 820\ mg/dose$

Answer: The prescribed dose of 850 mg IV is **NOT** safe for the child.

Note: If an accurate weight is unavailable when needed to provide weight-based interventions, such as in emergent situations, it is recommended to use a length-based measurement tool such as a Broselow tape. This is a pediatric emergency tape that provides a rapid estimate of a child's weight based on the child's recumbent length.

BOX 42.5 Calculating Medication Dosage Based on BSA

When dosage recommendations for children specify milligrams, micrograms, or units per square meter, calculating the dosage is simple multiplication.

Example: The dosage recommendation is 4 mg/m^2. The child has a body surface area of 1.1 m^2. What is the dosage to be administered?

Answer: ***4.4 mg***

$1.1 \times 4\ mg = 4.4\ mg$

BOX 42.6 Calculating a Child's Dosage from the Adult Dosage

When dosages are specified only for adults, a formula is used to calculate a child's dosage from the adult dosage. The adult dosage is based on a standardized body surface area (BSA) of 1.73 m^2.

Example: A pediatrician has prescribed an antibiotic for a child. The average adult dose is 250 mg. The child has a BSA of 0.41 m^2. What is the dose for the child?

Answer: ***59.24 mg***

Formula: $\frac{BSA\ of\ a\ child\ (m^2)}{1.73m^2} \times Adult\ dose = Child's\ dose$

$\frac{0.41}{1.73} \times 250\ mg = 59.24\ mg$

Telegram & Insta: NCLEX_RN_Edu

BOX 42.7 Developmental Considerations for Administering Medications

Infants

Perform procedure quickly, allowing the infant to swallow small amounts at a time; then offer comfort measures, such as holding, rocking, and cuddling.
Allow self-comforting measures, such as the use of a pacifier.

Toddlers

Offer a brief, concrete explanation of the procedure and then perform it.
Accept aggressive behavior, within reasonable limits, as a healthy response, and provide outlets for the toddler.
Provide comfort measures immediately after the procedure, such as touch, holding, cuddling, and providing a favorite toy.

Preschoolers

Offer a brief, concrete explanation of the procedure and then perform it.
Accept aggressive behavior, within reasonable limits, as a healthy response, and provide outlets for the child.
Provide comfort measures after the procedure, such as touch, holding, or providing a favorite toy.

School-Age Children

Explain the procedure, allowing for some control over the body and situation.
Explore feelings and concepts through therapeutic play, drawings of own body and self in the hospital, and the use of books and realistic hospital equipment.
Set appropriate behavior limits, such as it is all right to cry or scream, but not to bite.
Provide activities for releasing aggression and anger.
Use the opportunity to teach about how medication helps the disorder.

Adolescents

Explain the procedure, allowing for some control over body and situation.
Explore concepts of self, hospitalization, and illness, and correct any misconceptions.
Encourage self-expression, individuality, and self-care needs.
Encourage participation in the procedure.

Data from Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing*. (10th ed.). St. Louis: Elsevier. pp. 614-615; McKenry, L., & Salerno, E. (2003). *Mosby's pharmacology in nursing*. St. Louis: Mosby.

PRACTICE QUESTIONS

1. The nurse is providing medication instructions to a parent. Which statement by the parent indicates a **need for further instruction?**
1. "I need to cuddle my child after giving the medication."
2. "I can give my child a frozen juice bar after my child swallows the medication."
3. "I need to mix the medication in the baby food and give it when I feed my child."
4. "If my child does not like the taste of the medicine, I need to encourage my child to pinch the nose and drink the medication through a straw."

2. A pediatrician's prescription reads "ampicillin sodium 125 mg IV every 6 hours." The medication label reads "when reconstituted with 7.4 mL of bacteriostatic water, the final concentration is 1 g/7.4 mL." The nurse prepares to draw up how many milliliters to administer 1 dose?
1. 1.1 mL
2. 0.54 mL
3. 7.425 mL
4. 0.925 mL

3. A pediatric client with ventricular septal defect repair is placed on a maintenance dosage of digoxin. The dosage is 8 mcg/kg/day, and the client's weight is 7.2 kg. The pediatrician prescribes the digoxin to be given twice daily. The nurse prepares how many mcg of digoxin to administer to the child at each dose?
1. 12.6 mcg
2. 21.4 mcg
3. 28.8 mcg
4. 32.2 mcg

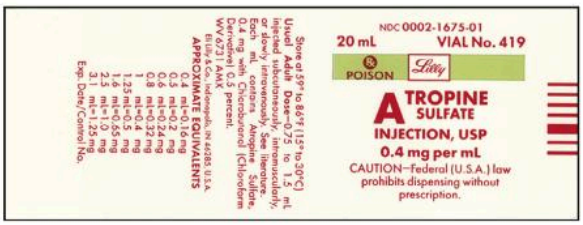
4. Sulfisoxazole, 1 g orally twice daily, is prescribed for an adolescent with a urinary tract infection. The medication label reads "500-mg tablets." The nurse has determined that the dosage prescribed is safe. The nurse administers how many tablets per dose to the adolescent?
1. ½ tablet
2. 1 tablet
3. 2 tablets
4. 3 tablets

5. Penicillin G procaine, 1,000,000 units IM (intramuscularly), is prescribed for an adolescent with an infection. The medication label reads "1,200,000 units per 2 mL." The nurse has determined that the dose prescribed is safe. The nurse administers how many milliliters per dose to the adolescent? **Round answer to the nearest tenth position.**
1. 0.8 mL
2. 1.2 mL
3. 1.4 mL
4. 1.7 mL

6. The nurse prepares to administer an intramuscular injection to a 4-month-old infant. The nurse selects which **best** site to administer the injection?
1. Gluteus
2. Lateral deltoid
3. Rectus femoris
4. Vastus lateralis

Telegram & Insta: NCLEX_RN_Edu

7. Atropine sulfate, 0.6 mg intramuscularly, is prescribed for a child preoperatively. The nurse has determined that the dose prescribed is safe and prepares to administer how many milliliters to the child? **Fill in the blank (refer to figure).**



Answer: _____ mL

ANSWERS

1. *Answer:* 3

Rationale: The nurse would teach the parent to avoid putting medications in foods because it may give an unpleasant taste to the food, and the child may refuse to accept the same food in the future. In addition, the child may not consume the entire serving and would not receive the required medication dosage. The parent needs to provide comfort measures—such as touching, holding, cuddling, or providing a favorite toy—immediately after medication administration. The parent could offer juice, a soft drink, or a frozen juice bar to the child after the child swallows the medication. If the taste of the medication is unpleasant, the child would pinch the nose and drink the medication through a straw.

Test-Taking Strategy: Note the **strategic words,** *need for further instruction.* These words indicate a **negative event query** and the need to select the incorrect statement made by the parent. Read each statement carefully and think about which statement may reflect an unsafe practice and may provide an inaccurate dose to the child. This will direct you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. p. 709.

2. *Answer:* 4

Rationale: Convert 1 g to milligrams. In the metric system, to convert a larger unit to a smaller unit, multiply by 1000 or move the decimal point 3 places to the right: 1 g = 1000 mg

Formula:

$$\frac{Desired}{Available} \times Volume = \frac{125\ mg}{1000\ mg} \times 7.4\ mL = 0.925\ mL\ per\ dose$$

Test-Taking Strategy: Focus on the **subject,** milliliters per dose. Convert grams to milligrams first. Next, use the formula to determine the correct dose, knowing that when reconstituted, 1000 mg = 7.4 mL. Verify the answer using a calculator.

Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. p. 598.

3. *Answer:* 3

Rationale: Calculate the daily dosage by weight first:
8 mcg × 7.2 kg = 57.6 mcg/day

The pediatrician prescribes digoxin twice daily; 2 doses in 24 hours will be administered:

$$\frac{57.6\ mcg/day}{2\ doses} = 28.8\ mcg\ for\ each\ dose$$

Test-Taking Strategy: Focus on the **subject,** mcg per dose, and note that the question states *twice daily* and *each dose*. Calculate the dosage per day by weight first, and then determine the micrograms per each dose by dividing the total daily dose by 2. Verify the answer using a calculator.

Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 600-601.

4. *Answer:* 3

Rationale: Change 1 g to milligrams, knowing that 1000 mg = 1 g. Also, when converting from grams to milligrams (larger unit to smaller unit), move the decimal point 3 places to the right:
1 g = 1000 mg

Next, use the formula to calculate the correct dose.

Formula: $$\frac{Desired}{Available} \times Tablet = \frac{1000\ mg}{500\ mg} \times Tablet = 2\ tablets$$

Test-Taking Strategy: Focus on the **subject,** tablets per dose. Convert grams to milligrams first. Next, use the formula to determine the correct dose, and verify the answer using a calculator.

Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 599-600.

5. *Answer:* 4

Rationale: Use the medication calculation formula.

Formula:

$$\frac{Desired}{Available} \times Volume = \frac{1,000,000}{1,200,000} \times 2\ mL = 1.66 = 1.7\ mL\ per\ dose$$

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Focus on the **subject,** milliliters per dose. Use the formula to determine the correct dose, and verify the answer using a calculator. Remember to round the answer to the nearest tenth position.

Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 600-601.

6. *Answer:* 4

Rationale: Intramuscular injection sites are selected on the basis of the child's age and muscle development of the child. The vastus lateralis is the best muscle group to use for intramuscular injection in a 4-month-old infant. The sites identified in options 1, 2, and 3 are unsafe for a child of this age.

Test-Taking Strategy: Note the **strategic word,** *best*, and focus on the age of the child identified in the question. Thinking about the physiological development of the muscle groups in an infant at 4 months of age will assist in directing you to the correct option.

Reference: Hockenberry, M., Wilson, D., & Rodgers, C. (2019). *Wong's nursing care of infants and children.* (11th ed.). St. Louis: Elsevier. pp. 711-713.

7. *Answer:* 1.5

Rationale: Use the formula for calculating the medication dose.

Formula: $\frac{Desired}{Available} \times Volume = \frac{0.6\ mg}{0.4\ mg} \times 1\ mL = 1.5\ mL$

Test-Taking Strategy: Focus on the **subject,** the milliliters to be administered. Note that the medication label indicates that there is 0.4 mg/mL. Use the formula to determine the correct dose, and verify the answer using a calculator.

Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 599-600.

UNIT VII

Integumentary Problems of the Adult Client

Pyramid to Success

The integumentary system provides the first line of defense against infections. Protective measures to prevent infection are a priority, including infection from colonization with a multidrug-resistant organism, such as methicillin-resistant *Staphylococcus aureus* (MRSA). Pyramid Points address the risk factors related to the development of integumentary problems, recognizing cues indicative of an infection, and the preventive measures related to integumentary problems, including skin cancer. Another important focus are the emergency measures related to bites and stings. Psychosocial issues related to the body image disturbances that can occur as the result of an integumentary problem and providing psychosocial support is a primary nursing consideration.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Consulting with interprofessional health care team members regarding treatments
Ensuring that informed consent has been obtained for treatments and procedures
Handling of hazardous and infectious materials
Instituting standard and other precautions
Maintaining confidentiality related to the skin problem
Making referrals to appropriate interprofessional health care team members
Practicing asepsis techniques
Prioritizing hypotheses based on client's needs
Taking action to prevent infections and other complications of integumentary problems

Health Promotion and Maintenance

Generating solutions for disease prevention measures
Performing physical assessment techniques for the integumentary system
Prioritizing client problems related to the integumentary problem
Promoting health screening and health promotion programs to prevent skin problems
Providing instructions to the client regarding prevention measures and care for an integumentary problem

Psychosocial Integrity

Discussing unexpected body image changes
Identifying coping mechanisms
Identifying situational role changes
Identifying support systems
Providing support to the client to assist in coping with the integumentary problem

Physiological Integrity

Analyzing cues related to alterations in body systems
Evaluating outcomes of treatment and care
Monitoring for fluid and electrolyte imbalances and other complications
Monitoring for signs of infection
Monitoring laboratory reference intervals
Performing wound care
Providing adequate nutrition for healing
Providing basic care and comfort
Providing emergency care for an integumentary injury
Taking action if a complication arises

CHAPTER 43

Integumentary Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

Telegram & Insta: NCLEX_RN_Edu

PRIORITY CONCEPTS Infection; Tissue Integrity

I. Anatomy and Physiology

A. The skin is the largest sensory organ of the body, with a surface area of 15 to 20 square feet (1.4 to 1.9 square meters) and a weight of about 9 lb (4 kg).

B. Functions

1. Acts as the first line of defense against infections
2. Protects underlying tissues and organs from injury
3. Receives stimuli from the external environment; detects touch, pressure, pain, and temperature stimuli; relays information to the nervous system
4. Regulates normal body temperature
5. Excretes salts, water, and organic wastes
6. Protects the body from excessive water loss
7. Synthesizes vitamin D_3, which converts to calcitriol, for normal calcium metabolism
8. Stores nutrients

C. Layers

1. Epidermis
2. Dermis
3. Hypodermis (subcutaneous fat)

D. Epidermal appendages

1. Nails
2. Hair
3. Glands
   - **a.** Sebaceous
   - **b.** Sweat

E. Normal bacterial flora

1. Types of normal bacterial flora include:
   - **a.** Gram-positive and gram-negative staphylococci
   - **b.** *Pseudomonas*
   - **c.** *Streptococcus*
2. Organisms are shed with normal exfoliation.
3. A pH of 4.2 to 5.6 halts the growth of bacteria.

II. Risk Factors for Integumentary Problems

A. Exposure to chemical and environmental pollutants

B. Exposure to radiation

C. Race and age

D. Exposure to the sun or use of indoor tanning

E. Lack of personal hygiene habits

F. Use of harsh soaps or other harsh products

G. Some medications, such as long-term glucocorticoid use or herbal preparations

H. Nutritional deficiencies

I. Moderate to severe emotional stress

J. Infection, with injured areas as the potential entry points for infection

K. Repeated injury and irritation

L. Genetic predisposition

M. Systemic illnesses

III. Psychosocial Impact Related to Integumentary Problems

A. Change in body image, decreased general well-being, and decreased self-esteem

B. Social isolation and fear of rejection (because of embarrassment about changes in skin appearance)

C. Restrictions in physical activity

D. Pain

E. Disruption or loss of employment

F. Cost of medications, hospitalizations, and follow-up care, including dressing supplies

IV. Phases of Wound Healing

A. Phases

1. Inflammatory: Begins at the time of injury and lasts 3 to 5 days; manifestations include local edema, pain, redness, itchiness, warmth, and possible exudate.

Telegram & Insta: NCLEX_RN_Edu

2. Fibroblastic: Begins the fourth day after injury and lasts 2 to 4 weeks; scar tissue forms and granulation tissue forms in the tissue bed.
3. Maturation: Begins as early as 3 weeks after the injury and may last for 1 year; scar tissue becomes thinner and is firm and inelastic on palpation.

B. Healing by intention
1. First intention: Wound edges are approximated and held in place (i.e., with sutures) until healing occurs; wound is easily closed and dead space is eliminated.
2. Second intention: This type of healing occurs with injuries or wounds that have tissue loss and require gradual filling in of the dead space with connective tissue.
3. Third intention: This type of healing involves delayed primary closure and occurs with wounds that are intentionally left open for several days for irrigation or removal of debris and exudates; once debris has been removed and inflammation resolves, the wound is closed by first intention.

C. Types of wound drainage: Refer to Box 43.1.

BOX 43.1 Types of Drainage from Wounds

Serous
- Clear or straw-colored
- Occurs as a normal part of the healing process

Serosanguineous
- Pink-colored due to the presence of a small amount of blood cells mixed with serous drainage
- Occurs as a normal part of the healing process

Sanguineous
- Red drainage from trauma to a blood vessel
- May occur with wound cleansing or other trauma to the wound bed
- Sanguineous drainage is abnormal in wounds.

Hemorrhaging
- Frank blood from a leaking blood vessel
- May require emergency treatment to control bleeding
- Hemorrhage is an abnormal wound exudate.

Purulent
- Yellow, gray, or green drainage due to infection in the wound

V. Diagnostic Tests

A. Skin biopsy
1. Description
   a. Skin biopsy is the collection of a small piece of skin tissue for histopathological study.
   b. Methods include punch, excisional, and shave.
2. Preprocedure interventions
   a. Verify that informed consent has been obtained.
   b. Cleanse site as prescribed.
3. Postprocedure interventions
   a. Place specimen in the appropriate container and send to pathology laboratory for analysis.
   b. Use surgically aseptic technique for biopsy site dressings.
   c. Assess the biopsy site for bleeding and infection.
   d. Instruct the client to keep dressing in place for at least 8 hours; then clean daily and use antibiotic ointment as prescribed (sutures are usually removed in 7 to 10 days).
   e. Instruct the client to report signs of excessive drainage, redness, or other signs of infection.

B. Skin/wound cultures
1. A small skin culture sample is obtained with a sterile applicator and the appropriate type of culture tube (e.g., bacterial or viral). Methods include scraping, punch biopsy, and collecting fluid. Local anesthesia may be used.
2. A nasal swab is also commonly done to determine previous exposure to certain types of bacteria.
3. Postprocedure intervention
   a. Viral culture is placed immediately on ice.
   b. Sample is sent to the laboratory to identify an existing organism.

⚠ Obtain skin culture samples or any other type of culture specimens before instituting antibiotic therapy.

C. Wood's light examination (black light test or UV test)
1. Description: Skin is viewed under ultraviolet light through a special glass (Wood's glass) to identify superficial infections of the skin.
2. Preprocedure intervention: Explain the procedure to the client, reassuring the client that the light is not harmful to the skin or the eyes. Darken the room before the examination.
3. Postprocedure intervention: Assist the client during adjustment from the darkened room.

D. Diascopy
1. Technique allows clearer inspection of lesions by eliminating the erythema caused by increased blood flow to the area.
2. A glass slide is pressed over the lesion, causing blanching and revealing the lesion more clearly.

E. Skin assessment: See Chapter 12.

VI. *Candida albicans*

A. Description
1. A superficial fungal infection of the skin and mucous membranes
2. Also known as a *yeast infection* (oral candidiasis), or *thrush* when it occurs in the mouth

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Risk factors include immunosuppression, long-term antibiotic therapy, medications, diabetes mellitus, and obesity.
4. Common areas of occurrence include skinfolds, perineum, vagina, axilla, and under the breasts.

B. Assessment
1. Skin: Red and irritated appearance that itches and stings
2. Mucous membranes of the mouth: Red and whitish patches

C. Interventions
1. Teach the client to keep skinfold areas clean and dry.
2. For the hospitalized client, inspect skinfold areas frequently, turn and reposition the client frequently, and keep the skin and bed linens clean and dry.
3. Provide frequent mouth care as prescribed, and avoid irritating products.
4. Rinse mouth after some medications.
5. Provide food and fluids that are tepid in temperature and nonirritating to mucous membranes.
6. Antifungal medications may be prescribed.

VII. Herpes Zoster (Shingles)

A. Description
1. In clients with a history of chicken pox, shingles is caused by reactivation of the varicella-zoster virus; shingles can occur during any immunocompromised state in clients with a history of chicken pox.
2. The dormant virus is located in the dorsal nerve root ganglia of the sensory cranial and spinal nerves.
3. Herpes zoster eruptions occur in a segmental distribution on the skin area along the infected nerve and show up after several days of discomfort in the area.
4. Diagnosis is determined by visual examination and by Tzanck smear to verify a herpes infection and viral culture to identify the organism.
5. Postherpetic neuralgia (severe pain) can remain after the lesions resolve.
6. Herpes zoster is contagious to individuals who never had chicken pox and who have not been vaccinated against the disease.
7. Herpes simplex virus is another type of virus; type 1 infection typically causes a cold sore (usually on the lip), and type 2 causes genital herpes typically below the waist (both types are contagious and may be present together).

B. Assessment
1. Unilaterally clustered skin vesicles along peripheral sensory nerves on the trunk, thorax, or face
2. Fever, malaise
3. Burning and pain
4. Paresthesia
5. Pruritus

C. Interventions
1. Isolate the client, because exudate from the lesions contains the virus (maintain standard precautions and other precautions, such as contact precautions, as appropriate, as long as vesicles are present).
2. Assess for signs and symptoms of infection, including skin infections and eye infections; skin necrosis can also occur.
3. Assess neurovascular status and seventh cranial nerve function; Bell's palsy is a complication.
4. Use an air mattress and bed cradle on the client's bed if hospitalized, and keep the environment cool; warmth and touch aggravate the pain.
5. Prevent the client from scratching and rubbing the affected area.
6. Instruct the client to wear lightweight, loose cotton clothing and to avoid wool and synthetic clothing.
7. Teach the client about the prescribed therapies; astringent compresses may be prescribed to relieve irritation and pain and to promote crust formation and healing.
8. Teach the client about measures to keep the skin clean to prevent infection.
9. Teach the client about topical treatment and antiviral medications; antiviral therapies begun within 3 days of rash reduce pain and lessen the likelihood of postherpetic neuralgia.
10. The vaccination for shingles is recommended for adults 50 years of age and older to reduce the risk of occurrence and the associated long-term pain.
11. Antiviral medications may be prescribed; refer to Chapter 64 for information on antiviral medications.

VIII. Methicillin-Resistant *Staphylococcus aureus* (MRSA)

A. Description
1. Skin or wound becomes infected with methicillin-resistant *Staphylococcus aureus* (MRSA). MRSA can be community acquired, such as through sports when skin-to-skin contact and sharing of equipment occurs. It can also be hospital acquired, as in the case of a surgical site infection (SSI). See Chapter 13 for additional types of health care–associated infections.
2. A MRSA screening with a nasal swab may be done for clients who are having surgery, who have been previously hospitalized, or who live in group settings. Clients with positive cultures or with a history of a positive culture are isolated.
3. Infection can range from mild to severe and can present as folliculitis or furuncles.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Folliculitis is a superficial infection of the follicle caused by *Staphylococcus* and presents as a raised red rash and pustules; furuncles are also caused by *Staphylococcus* and occur deep in the follicle, presenting as very painful large, raised bumps that may or may not have a pustule.
5. If MRSA infects the blood, sepsis, organ damage, and death can occur.

⚠ MRSA is contagious and is spread to others by direct contact with infected skin or infected articles; for the client with MRSA, the infection can also be spread to many parts of the body.

B. Assessment: A culture and sensitivity test of the skin or wound confirms the presence of MRSA and leads to choice of appropriate antibiotic therapy.

C. Interventions

1. Maintain standard precautions and contact precautions as appropriate to prevent spread of infection to others.
2. Monitor the client closely for signs of further infection, which may result in systemic illness or organ damage.
3. Administer antibiotic therapy as prescribed.
4. For additional information on MRSA, refer to Chapters 13 and 41.

IX. Erysipelas and Cellulitis

A. Description

1. Erysipelas is an acute, superficial infection affecting the upper layers of skin caused by group A *Streptococcus*, which enters the tissue via an abrasion, bite, trauma, or wound.
2. Cellulitis is an infection of the dermis and underlying hypodermis; the causative organism is usually group A *Streptococcus* or *Staphylococcus aureus.*

B. Assessment

1. Pain and tenderness
2. Erythema and warmth
3. Edema
4. Fever

C. Interventions

1. Promote rest of the affected area.
2. Apply warm compresses as prescribed to promote circulation and to decrease discomfort, erythema, and edema.
3. Apply antibacterial dressings, ointments, or gels as prescribed.
4. Administer antibiotics as prescribed for an infection; obtain a culture of the area before initiating the antibiotics.

X. Poison Ivy, Poison Oak, and Poison Sumac

A. Description: A dermatitis that develops from contact with urushiol from poison ivy, poison oak, or poison sumac plants

B. Assessment

1. Papulovesicular lesions
2. Severe pruritus

C. Interventions

1. Cleanse the skin of the plant oils immediately.
2. Apply cool, wet compresses to relieve the itching.
3. Apply topical products to relieve the itching and discomfort.
4. Topical or oral glucocorticoids may be prescribed for severe reactions.

XI. Bites and Stings

A. Spider bites

1. Almost all types of spider bites are venomous, and most are not harmful, but bites or stings from brown recluse spiders, black widow spiders, and tarantulas (as well as from scorpions, bees, and wasps) can produce toxic reactions in humans. Tetanus prophylaxis should be current because spider bites can be contaminated with tetanus spores.
2. Brown recluse spider
   a. Bite can cause a skin lesion, a necrotic wound, or systemic effects from the toxin (loxoscelism).
   b. Application of ice decreases enzyme activity of the venom and limits tissue necrosis; it should be done immediately and intermittently for up to 4 days after the bite.
   c. Topical antiseptics and antibiotics may be necessary if the site becomes infected.
3. Black widow spider
   a. Bite causes a small red papule.
   b. Venom causes neurotoxicity.
   c. Ice is applied immediately to inhibit the action of the neurotoxin.
   d. Systemic toxicity can occur, and the victim may require supportive therapy in the hospital.
4. Tarantulas
   a. Bite causes swelling, redness, numbness, lymph inflammation, and pain at the bite site.
   b. The tarantula launches its barbed hairs, which can penetrate the skin and eyes of the victim, producing a severe inflammatory reaction.
   c. Tarantula hairs are removed as soon as possible, using sticky tape to pull hairs from the skin, and the skin is thoroughly irrigated; saline irrigations are done for eye exposure.
   d. The involved extremity is elevated and immobilized to reduce pain and swelling.
   e. Antihistamines and topical or systemic corticosteroids may be prescribed; tetanus prophylaxis is necessary.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Scorpion stings

1. Scorpions inject venom into the victim through a stinging apparatus on their tail.
2. Most stings cause local pain, inflammation, and mild systemic reactions that are treated with analgesics, wound care, and supportive treatment.
3. The bark scorpion can inflict a severe and potentially fatal systemic response, especially in children and the elderly; the venom is neurotoxic; the victim should be taken to the emergency department immediately (an antivenom is administered for bark scorpion bites).

C. Bees and wasps

1. Stings usually cause a wheal and flare reaction.
2. Emergency care involves quick removal of the stinger and application of an ice pack.
3. The stinger is removed by gently scraping or brushing it off with the edge of a needle or similar object; tweezers are not used because there is a risk of pinching the venom sac.
4. If the victim is allergic to the venom of a bee or wasp, a severe allergic response can occur (hives, pruritus, swelling of the lips and tongue) that can progress to life-threatening anaphylaxis; immediate emergency care is required (see Clinical Judgment: Generate Solutions Box).

CLINICAL JUDGMENT: GENERATE SOLUTIONS

The nurse is preparing to teach a client with an allergy to bee stings about how to respond in case of a sting. The nurse plans to include the following teaching points:

- Individuals who are allergic need to carry an epinephrine autoinjector for self-administration of intramuscular epinephrine if a bee or wasp sting occurs.
- After use of the epinephrine autoinjector, the individual needs to seek emergency medical attention.
- Individuals need to have two injectors available and obtain a replacement as soon as possible.
- Monitor for rebound anaphylaxis, because the reaction is not always a single one. In some cases, symptoms of the reaction return hours or days after one receives an epinephrine injection.
- Diphenhydramine can be taken to assist in alleviating symptoms.

D. Snake bites

1. Some snakes are venomous and can cause a serious systemic reaction in the victim.
2. The victim should be immediately moved to a safe area away from the snake and should rest to decrease venom circulation; the extremity is immobilized and kept below the level of the heart.
3. Constricting clothing and jewelry are removed before swelling occurs.
4. The victim is kept warm and is not allowed to consume caffeinated or alcoholic beverages, which may speed absorption of the venom.
5. If unable to seek emergency medical attention promptly, a constricting band may be applied proximal to the wound to slow the venom circulation; monitor the circulation frequently and loosen the band if edema occurs.
6. The wound is not incised or sucked to remove the venom; ice is not applied to the wound.
7. Emergency care in a hospital is required as soon as possible; an antivenom may be administered along with supportive care. The snake should not be transported with the victim for identification purposes unless it can be safely placed in a sealed container during transportation.

For spider bites, scorpion bites, or other stings or bites, the Poison Control Center needs to be contacted as soon as possible to determine the best initial management.

XII. Frostbite

A. Description

1. Frostbite is damage to tissues and blood vessels as a result of prolonged exposure to cold.
2. Fingers, toes, face, nose, and ears often are affected.

B. Assessment

1. First-degree: Involves white plaque surrounded by a ring of hyperemia and edema
2. Second-degree: Large, clear fluid–filled blisters with partial-thickness skin necrosis
3. Third-degree: Involves the formation of small hemorrhagic blisters, usually followed by eschar formation involving the hypodermis requiring debridement
4. Fourth-degree: No blisters or edema noted; full-thickness necrosis with visible tissue loss extending into muscle and bone, which may result in gangrene. Amputation may be required.

C. Interventions

1. Rewarm the affected part rapidly and continuously with a warm water bath or towels at 104.0° F to 107.6° F (40° C to 42° C) to thaw the frozen part.
2. Handle the affected area gently and immobilize.
3. Avoid using dry heat, and never rub or massage the part, which may result in further tissue damage.
4. The rewarming process may be painful; analgesics may be necessary.
5. Avoid compression of the injured tissues, and apply only loose and nonadherent sterile dressings.
6. Monitor for signs of compartment syndrome.
7. Tetanus prophylaxis is necessary, and topical and systemic antibiotics may be prescribed.
8. Debridement of necrotic tissue may be needed; amputation may be necessary if gangrene develops.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

XIII. Actinic Keratoses

A. Actinic keratoses are caused by chronic exposure to the sun and appear as rough, scaly, red, or brown lesions that are usually found on the face, scalp, arms, and backs of the hands.

B. Lesions are considered premalignant, and there is risk for slow progression to squamous cell carcinoma.

C. Treatment includes medications, excision, cryotherapy, curettage, and laser therapy.

D. See Chapter 44 for information on medications to treat this disorder.

XIV. Skin Cancer

A. Description

1. Skin cancer is a malignant lesion of the skin, which may or may not metastasize.
2. Overexposure to the sun is a primary cause; other causes and conditions that place the individual at risk include chronic skin damage from repeated injury and irritation such as tanning and use of tanning beds, genetic predisposition, ionizing radiation, light-skinned race, age older than 60 years, an outdoor occupation, and exposure to chemical carcinogens.
3. Diagnosis is confirmed by skin biopsy.

B. Types

1. Basal cell: Basal cell cancer arises from the basal cells contained in the epidermis; metastasis is rare, but underlying tissue destruction can progress to organ tissue.
2. Squamous cell: Squamous cell cancer is a tumor of the epidermal keratinocytes and can infiltrate surrounding structures and metastasize to lymph nodes.
3. Melanoma: Melanoma may occur any place on the body, especially where birthmarks or new moles are apparent; it is highly metastatic to the brain, lungs, bone, and liver, with survival depending on early diagnosis and treatment.

C. Assessment (see Box 43.2)

1. Change in color, size, or shape of preexisting lesion
2. Pruritus
3. Local soreness

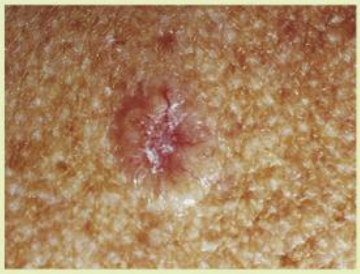
The client needs to be informed about the risks associated with overexposure to the sun and taught about the importance of performing monthly skin self-assessments.

D. Interventions

1. Instruct the client regarding the risk factors and preventive measures.
2. Instruct the client to perform monthly skin self-assessments and to monitor for lesions that do not heal or that change characteristics.
3. Advise the client to have moles or lesions that are subject to chronic irritation removed.
4. Advise the client to avoid contact with chemical irritants.
5. Instruct the client to wear layered clothing and use and reapply sunscreen lotions with an appropriate sun protection factor when outdoors.
6. Instruct the client to avoid sun exposure between 10 a.m. and 4 p.m.

BOX 43.2 Appearance of Skin Cancer Lesions

Basal Cell Carcinoma

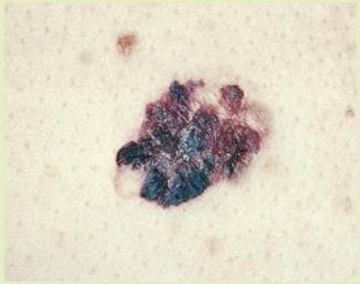


Waxy nodule with pearly borders
Papule, red, central crater
Metastasis is rare

Squamous Cell Carcinoma

Oozing, bleeding, crusting lesion
Potentially metastatic
Larger tumors associated with a higher risk for metastasis

Melanoma



Irregular, circular, bordered lesion with hues of tan, black, or blue
Rapid infiltration into tissue; highly metastatic

Figures from Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 468.

Telegram & Insta: NCLEX_RN_Edu

7. Management may include surgical or nonsurgical interventions; if medication is prescribed, provide instructions about its use.
8. Assist with surgical management, which may include cryosurgery, curettage and electrodessication, or surgical excision of the lesion.

XV. Psoriasis

A. Description

1. Psoriasis is a chronic, noninfectious skin inflammation occurring with remissions and exacerbations involving keratin synthesis that results in psoriatic patches; it may lead to an infection in the affected area.
2. Various forms exist, with psoriasis vulgaris being the most common.
3. Possible causes of the disorder include stress, trauma, infection, hormonal changes, obesity, an autoimmune reaction, and climate changes; a genetic predisposition may also be a cause.
4. The disorder may be exacerbated by the use of certain medications.
5. Koebner phenomenon is the development of psoriatic lesions at a site of injury, such as a scratched or sunburned area. Prompt cleansing of the area may prevent or lessen this phenomenon.
6. In some individuals with psoriasis, arthritis develops, which leads to joint changes similar to those seen in rheumatoid arthritis.
7. The goal of therapy is to reduce cell proliferation and inflammation, and the type of therapy prescribed depends on the extent of the disease and the client's response to treatment.

B. Assessment

1. Pruritus
2. Shedding: Silvery-white scales on a raised, reddened, round plaque that usually affects the scalp, knees, elbows, extensor surfaces of arms and legs, and sacral regions
3. Yellow discoloration, pitting, and thickening of the nails are noted if they are affected.
4. Joint inflammation with psoriatic arthritis

C. Pharmacological therapy: Refer to Chapter 44 for medications used to treat psoriasis.

D. Interventions and client education

1. Provide emotional support to the client with associated altered body image and decreased self-esteem.
2. Instruct the client in the use of prescribed therapies and to avoid over-the-counter medications.
3. Instruct the client not to scratch the affected areas and to keep the skin lubricated as prescribed to minimize itching.
4. Monitor for and instruct the client to recognize and report the signs and symptoms of secondary skin problems, such as infection.
5. Instruct the client to wear light cotton clothing over affected areas.
6. Assist the client to identify ways to reduce stress if stress is a predisposing factor.

XVI. Acne Vulgaris

A. Description

1. Acne is a chronic skin disorder that usually begins in puberty; lesions develop on the face, neck, chest, shoulders, and back.
2. Acne requires active treatment for control until it resolves.
3. The types of lesions include comedones (open and closed), pustules, papules, and nodules.
4. The exact cause is unknown but may include androgenic influence on sebaceous glands, increased sebum production, and proliferation of *Propionibacterium acnes*, the organism that converts sebum into irritant fatty acids.
5. Exacerbations coincide with the menstrual cycle because of hormonal activity; oily skin and a genetic predisposition may be contributing factors.

B. Assessment

1. Closed comedones are whiteheads and noninflamed lesions that develop as follicles enlarge, with the retention of horny cells.
2. Open comedones are blackheads that result from continuing accumulation of horny cells and sebum, which dilates the follicles.
3. Pustules and papules result as the inflammatory process progresses.
4. Nodules result from total disintegration of a comedone and subsequent collapse of the follicle.
5. Deep scarring can result from nodules.

C. Interventions

1. Instruct the client in prescribed skin-cleansing methods, with emphasis on not scrubbing the face and using only prescribed topical agents.
2. Instruct the client in the administration of topical or oral medications as prescribed.
3. Instruct the client not to squeeze, prick, or pick at lesions.
4. Instruct the client to use products labeled noncomedogenic and cosmetics that are water based and to avoid contact with products with an excessive oil base.
5. Instruct the client on the importance of follow-up treatment.
6. Refer to Chapter 44 for information on the medications used to treat acne.

XVII. Stevens-Johnson Syndrome

A. A medication-induced skin reaction that occurs through an immunological response; common medications causing the reaction include antibiotics (especially sulfonamides), antiseizure medications, and nonsteroidal antiinflammatory drugs (NSAIDs).

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. The syndrome is similar to toxic epidermal necrolysis (TEN), another medication-induced skin reaction that results in diffuse erythema and large blister formation on the skin and mucous membranes.

C. May be mild or severe, and may cause vesicles, erosions, and crusts on the skin; if severe, systemic reactions occur that involve the respiratory system, renal system, and eyes, resulting in blindness, and it can be fatal. Initial clinical manifestations include flu-like symptoms and erythema of the skin and mucous membranes. Serious systemic symptoms and complications occur when the ulcerations involve the larynx, bronchi, and esophagus.

D. Most commonly occurs in clients who have impaired immune systems

E. Treatment includes immediate discontinuation of the medication causing the syndrome; antibiotics, corticosteroids, and supportive therapy may be necessary.

XVIII. Pressure Injury (Refer to Chapter 16 for information on Pressure Injuries)

PRACTICE QUESTIONS

1. The nurse is conducting a session about the principles of first aid and is discussing the interventions for a snakebite to an extremity. The nurse would inform those attending the session that the **first priority** intervention in the event of this occurrence is which action?

1. Immobilize the affected extremity.
2. Remove jewelry and constricting clothing from the victim.
3. Place the extremity in a position so that it is below the level of the heart.
4. Move the victim to a safe area away from the snake and encourage the victim to rest.

2. A client calls the emergency department after experiencing direct contact with poison ivy shrubs. The client tells the nurse that nothing is visible on the skin and asks what to do. The nurse would provide which response?

1. "Come to the emergency department."
2. "Apply calamine lotion immediately to the exposed skin areas."
3. "Take a shower immediately, lathering and rinsing several times."
4. "It is not necessary to do anything if you cannot see anything on your skin."

3. A client is being admitted to the hospital for treatment of acute cellulitis of the lower left leg. During the admission assessment, the nurse expects to note which finding?

1. An inflammation of the epidermis only
2. A skin infection of the dermis and underlying hypodermis
3. An acute superficial infection of the upper layers of the skin
4. An epidermal and lymphatic infection caused by *Staphylococcus*

4. The clinic nurse assesses the skin of a client with psoriasis after the client has used a new topical treatment for 2 months. The nurse identifies which characteristics as improvement in the manifestations of psoriasis? **Select all that apply.**

- ❑ 1. Presence of striae
- ❑ 2. Palpable radial pulses
- ❑ 3. Absence of any ecchymosis on the extremities
- ❑ 4. Thinner reddish papules and a decrease in their number
- ❑ 5. Scarce amount of silvery-white scaly patches on the arms

5. The clinic nurse notes that the health care provider has documented a diagnosis of herpes zoster (shingles) in the client's chart. Based on an understanding of the cause of this disorder, the nurse determines that this definitive diagnosis was made by which diagnostic test?

1. Positive patch test
2. Positive culture results
3. Abnormal biopsy results
4. Wood's light examination indicative of infection

6. A client returns to the clinic for follow-up treatment after a skin biopsy of a suspicious lesion performed 1 week ago. The biopsy report indicates that the lesion is a melanoma. The nurse recognizes that melanoma has which characteristics? **Select all that apply.**

- ❑ 1. Lesion is painful to touch.
- ❑ 2. Lesion is highly metastatic.
- ❑ 3. Lesion is a nevus that has changes in color.
- ❑ 4. Skin under the lesion is reddened and warm to touch.
- ❑ 5. Lesion occurs in body areas exposed to outdoor sunlight.

7. When assessing a lesion diagnosed as basal cell carcinoma, the nurse **most likely** expects to note which findings? **Select all that apply.**

- ❑ 1. An irregularly shaped lesion
- ❑ 2. A small papule with a dry, rough scale
- ❑ 3. A firm, nodular lesion topped with crust
- ❑ 4. A pearly papule with a central crater and a waxy border
- ❑ 5. Location in the bald spot atop the head that is exposed to outdoor sunlight

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. A client arriving at the emergency department has experienced frostbite to the right hand. Which finding would the nurse note on assessment of the client's hand?
   1. A pink edematous hand
   2. Fiery red skin with edema in the nail beds
   3. Black fingertips surrounded by an erythematous rash
   4. A white color to the skin, which is insensitive to touch

9. The staff nurse reviews the nursing documentation in a client's chart and notes that the wound care nurse has documented that the client has a stage II pressure injury in the sacral area. Which finding would the nurse expect to note on assessment of the client's sacral area?
   1. Intact skin
   2. Full-thickness skin loss
   3. Exposed bone, tendon, or muscle
   4. Partial-thickness skin loss of the dermis

10. The nurse manager is planning the clinical assignments for the day. Which staff members cannot be assigned to care for a client with herpes zoster? **Select all that apply.**
    - ❑ 1. The nurse who never had roseola
    - ❑ 2. The nurse who never had mumps
    - ❑ 3. The nurse who never had chicken pox
    - ❑ 4. The nurse who never had German measles
    - ❑ 5. The nurse who never received the varicella-zoster vaccine

ANSWERS

1. *Answer:* 4
Rationale: In the event of a snakebite, the first priority is to move the victim to a safe area away from the snake and encourage the victim to rest to decrease venom circulation. Next, jewelry and constricting clothing are removed before swelling occurs. Immobilizing the extremity and maintaining the extremity below heart level would be done next; these actions limit the spread of the venom. The victim is kept warm and calm. Stimulants such as alcohol or caffeinated beverages are not given to the victim because these products may speed the absorption of the venom. The victim needs to be transported to an emergency facility as soon as possible.
Test-Taking Strategy: Note the **strategic words,** *first priority*. Eliminate options 1 and 3 first because they are **comparable or alike** and relate to positioning of the affected extremity. For the remaining options, think about them and visualize each. Moving the victim to a safe area is the priority to prevent further injury from the snake.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 213.

2. *Answer:* 3
Rationale: When an individual comes in contact with a poison ivy plant, the sap from the plant forms an invisible film on the human skin. The client should be instructed to cleanse the area by showering immediately and to lather the skin several times and rinse each time in running water. Removing the poison ivy sap will decrease the likelihood of irritation. Calamine lotion may be one product recommended for use if dermatitis develops. The client does not need to be seen in the emergency department at this time.
Test-Taking Strategy: Focus on the **subject,** contact with poison ivy. Recalling that dermatitis can develop from contact with an allergen and that contact with poison ivy results in an invisible film will assist in directing you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1618.

3. *Answer:* 2
Rationale: Cellulitis is an infection of the dermis and underlying hypodermis that results in a deep red erythema without sharp borders and spreads widely throughout tissue spaces. The skin is erythematous, edematous, tender, and sometimes nodular. Erysipelas is an acute, superficial, infection affecting the upper layers of the skin. Cellulitis is not superficial and extends deeper than the epidermis.
Test-Taking Strategy: Eliminate options 3 and 4 because they are **comparable or alike** and address the lymphatics. Eliminate option 1 because of the **closed-ended word** "only."
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 415.

4. *Answer:* 4, 5
Rationale: Psoriasis skin lesions include thick reddened papules or plaques covered by silvery-white patches. A decrease in the severity of these skin lesions is noted as an improvement. The presence of striae (stretch marks), palpable pulses, or lack of ecchymosis is not related to psoriasis.
Test-Taking Strategy: Focus on the **subject,** manifestations of psoriasis. Use knowledge regarding the pathophysiology and signs and symptoms associated with psoriasis. This will direct you to the correct options detailing a decrease in the psoriatic signs.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 421-422, 426.

5. *Answer:* 2
Rationale: With the classic presentation of herpes zoster, the clinical examination is diagnostic. However, a viral culture

Telegram & Insta: NCLEX_RN_Edu

of the lesion provides the definitive diagnosis. Herpes zoster (shingles) is caused by a reactivation of the varicella-zoster virus, the virus that causes chicken pox. A patch test is a skin test that involves the administration of an allergen to the surface of the skin to identify specific allergies. A biopsy would provide a cytological examination of tissue. In a Wood's light examination, the skin is viewed under ultraviolet light to identify superficial infections of the skin.

Test-Taking Strategy: Focus on the **subject,** diagnosing herpes zoster. Recalling that herpes zoster is caused by a virus will assist in directing you to the correct option. Also remember that a biopsy will determine tissue type, whereas a culture will identify an organism.

References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 454; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 417.

6. *Answer:* 2, 3

Rationale: Melanomas are pigmented malignant lesions originating in the melanin-producing cells of the epidermis. Melanomas cause changes in a nevus (mole), including color and borders. This skin cancer is highly metastatic, and a person's survival depends on early diagnosis and treatment. Melanomas are not painful or accompanied by signs of inflammation. Although sun exposure increases the risk of melanoma, lesions may occur any place on the body, especially where birthmarks or new moles are apparent.

Test-Taking Strategy: Focus on the **subject,** characteristics of melanoma skin cancer. It is necessary to know the normal characteristics associated with melanoma to answer this question correctly. Also, recalling that melanomas are highly metastatic will assist in directing you to the correct options.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 412.

7. *Answer:* 4, 5

Rationale: Basal cell carcinoma appears as a pearly papule with a central crater and rolled waxy border. Exposure to ultraviolet sunlight is a major risk factor. A melanoma is an irregularly shaped pigmented papule or plaque with a red-, white-, or blue-toned color. Actinic keratosis, a premalignant lesion, appears as a small macule or papule with a dry, rough, adherent yellow or brown scale. Squamous cell carcinoma is a firm, nodular lesion topped with a crust or a central area of ulceration.

Test-Taking Strategy: Note the **strategic words,** *most likely*. Use knowledge about the various types of skin cancer. Recalling the characteristics and etiology of basal cell cancer will direct you to the correct options.

References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 467-468; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 412.

8. *Answer:* 4

Rationale: Assessment findings in frostbite include a white or blue color; the skin will be hard, cold, and insensitive to touch. As thawing occurs, flushing of the skin, the development of blisters or blebs, or tissue edema appears. Options 1, 2, and 3 are incorrect.

Test-Taking Strategy: Focus on the **subject,** assessment findings in frostbite. Noting the words *insensitive to touch* in the correct option should direct you to this option.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 217-218.

9. *Answer:* 4

Rationale: In a stage II pressure injury, the skin is not intact. Partial-thickness skin loss of the dermis has occurred. It presents as a shallow open ulceration with a red-pink wound bed, without slough. It may also present as an intact or open/ruptured serum-filled blister. The skin is intact in stage I. Full-thickness skin loss occurs in stage III. Exposed bone, tendon, or muscle is present in stage IV.

Test-Taking Strategy: Focus on the **subject,** assessment of a pressure injury, specifically a stage II injury. Use knowledge about the various stages of pressure injuries. Focusing on the words *stage II* and visualizing the appearance of a stage II pressure injury will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 168-169.

10. *Answer:* 3, 5

Rationale: The nurses who have not had chicken pox or did not receive the varicella-zoster vaccine are susceptible to the herpes zoster virus and should not be assigned to care for the client with herpes zoster. Nurses who have not contracted roseola, mumps, or rubella are not necessarily susceptible to herpes zoster. Herpes zoster (shingles) is caused by a reactivation of the varicella-zoster virus, the causative virus of chicken pox. Individuals who have not been exposed to the varicella-zoster virus or who did not receive the varicella-zoster vaccine are susceptible to chicken pox. Health care workers who are unsure of their immune status should have varicella titers done before exposure to a person with herpes zoster.

Test-Taking Strategy: Focus on the **subject,** risk for transmission of herpes zoster. Recalling that herpes zoster is caused by a reactivation of the varicella-zoster virus, the causative virus of chicken pox, will direct you to the correct options.

References: Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology.* (7th ed.). St. Louis: Elsevier. pp. 1028-1029; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 417.

CHAPTER 44

Integumentary Medications

Contributors: David Petersen, MSN-Ed, RN
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS Tissue Integrity; Safety

I. Poison Ivy Treatment (Box 44.1)

A. Treatment of lesions includes calamine lotion and commercial products that soothe lesions, wet compresses and solutions that are astringent and antiseptic, and/or colloidal oatmeal baths to relieve discomfort.

B. Topical corticosteroids are effective to prevent or relieve inflammation, especially when used before blisters form.

C. Oral corticosteroids may be prescribed for severe reactions, and an antihistamine to promote sleep such as diphenhydramine may be prescribed.

II. Medications to Treat Dermatitis (Box 44.2)

A. Description

1. Superficial inflammatory process involving primarily the epidermis; there are many types, some of which include atopic dermatitis, contact dermatitis, and stasis dermatitis.
2. May be treated with moisturizer and topical glucocorticoids (preferred treatment); systemic immunosuppressants may need to be prescribed if topical treatment is ineffective or with systemic exposure.

B. Topical immunosuppressants

1. Tacrolimus and pimecrolimus creams
2. Side and adverse effects include redness, burning, and itching; causes sensitization of the skin to sunlight. Treated areas should be protected from direct sunlight.
3. Tacrolimus may increase the risk of contracting varicella zoster infection in children.
4. Tacrolimus may increase the risk of developing **skin cancer** and **lymphoma.**

BOX 44.1 Poison Ivy Treatment Products

- Calamine lotion
- Hydrocortisone (local exposure)
- Prednisone (systemic exposure)
- Pramoxine
- Zinc acetate; isopropanol
- Zinc acetate; isopropanol; benzyl alcohol

BOX 44.2 Medications to Treat Dermatitis

Systemic Immunosuppressants

- Azathioprine
- Cyclosporine
- Methotrexate
- Oral glucocorticoids

Topical Immunosuppressants

- Pimecrolimus 1% cream
- Tacrolimus

⚠ When administering any topical medication or topical patches, the nurse and family caregivers should always wear gloves to protect themselves from absorption of the medication. Caregivers should also be taught to wash their hands thoroughly before and after administration.

III. Topical Glucocorticoids

A. Description

1. Antiinflammatory, antipruritic, and vasoconstrictive actions
2. Preparations vary in potency and depend on the concentration and type of preparation and method of application (occlusive dressings enhance absorption, increasing the effects).
3. Systemic effects are more likely to occur with prolonged therapy and when extensive skin surfaces are treated (see Clinical Judgment: Generate Solutions Box).

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: GENERATE SOLUTIONS

The nurse is creating a plan of care for a client who had a topical glucocorticoid prescribed to treat an inflammatory skin condition scattered over various skin areas. The nurse plans to avoid the following skin areas with the understanding that topical glucocorticoids can be absorbed greater in these permeable skin areas.

- Scalp
- Axilla
- Face
- Neck
- Eyelids
- Perineum

The nurse also includes in the plan of care to wash the area just before application of the topical glucocorticoid and to apply the medication sparingly in a thin film, rubbing the area gently. Lastly, the nurse plans to monitor for signs of systemic absorption of the medication.

Topical glucocorticoids can be absorbed into the systemic circulation; absorption is greater in permeable skin areas (scalp, axilla, face and neck, eyelids, perineum) and less in areas where permeability is poor (palms, soles, back).

B. Contraindications
1. Clients demonstrating previous sensitivity to corticosteroids
2. Clients with current systemic fungal, viral, or bacterial infections
3. Clients with current complications related to glucocorticoid therapy

C. Local side and adverse effects
1. Burning, dryness, irritation, itching
2. Thinning of the skin, striae, purpura, and telangiectasia (causes threadlike red lines on the skin)
3. Skin atrophy
4. Acneiform eruptions
5. Hypopigmentation
6. Overgrowth of bacteria, fungi, and viruses

D. Systemic adverse effects
1. Growth retardation in children
2. Adrenal suppression
3. Cushing's syndrome
4. Ocular effects (glaucoma and cataracts)

E. Interventions
1. Wear gloves; wash the area just before application to ensure cleanliness and to increase medication penetration.
2. Apply sparingly in a thin film, rubbing gently.
3. Avoid the use of a dry occlusive dressing unless specifically prescribed by the primary health care provider (PHCP).
4. Instruct the client to report signs of adverse effects to the PHCP.
5. The monitoring of plasma cortisol levels may be prescribed if prolonged therapy is necessary.

In the adult, intact skin is generally impermeable to most topical medications. However, medications should not be applied to open areas unless prescribed, because undesired absorption and adverse effects can occur.

BOX 44.3 Medications to Treat Actinic Keratosis

- Aminolevulinic acid
- Diclofenac sodium 3% gel
- Fluorouracil
- Imiquimod 5% cream
- Ingenol mebutate

IV. Medications to Treat Actinic Keratosis (Box 44.3)

A. Description
1. Actinic keratoses are caused by prolonged exposure to the sun and appear as rough, scaly, red or brown lesions, usually found on the face, scalp, arms, and back of the hands.
2. Lesions can progress to squamous cell carcinoma.
3. Treatment includes medications and therapies such as excision, cryotherapy, curettage, and laser therapy.

B. Medications (see Box 44.3)
1. Diclofenac sodium
   a. A nonsteroidal antiinflammatory topical medication; it may take up to 3 months to be effective.
   b. Side and adverse effects include dry skin, itching, redness, and rash.
2. Fluorouracil
   a. A topical medication that affects DNA and RNA synthesis and causes a sequence of responses that results in healing; results are usually seen in 2 to 6 weeks but may take 1 to 2 months longer for complete healing.
   b. Side and adverse effects include itching, burning, inflammation, rash, and increased sensitivity to sunlight.
3. Imiquimod 5% cream
   a. In addition to treating actinic keratoses, this topical medication has been used to treat venereal warts; it may take up to 4 months to be effective.
   b. Side and adverse effects include redness, skin swelling, itching, burning, sores, blisters, scabbing, and crusting of the skin.
4. Ingenol mebutate
   a. Indicated for the topical treatment of actinic keratosis; application recommendations need to be followed closely because of the risks of severe allergic reaction and development of herpes zoster.
   b. Side and adverse effects include skin reactions, erythema, flaking/scaling, crusting, swelling, postulation, and erosion/ulceration; allergic reactions; herpes zoster.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

V. Sunscreens

A. Ultraviolet (UV) light can damage the skin and cause premalignant actinic keratoses and some types of skin cancer.

B. Sunscreens prevent the penetration of UV light and protect the skin.

C. Organic (chemical) sunscreens absorb UV light; inorganic (physical) sunscreens reflect and scatter UV light.

D. A sunscreen that protects against both UVB and UVA rays and one that has a sun protection factor (SPF) of at least 15 should be used.

E. Sunscreens are most effective when applied at least 30 minutes before exposure to the sun (sunscreens containing *para*-aminobenzoic acid or padimate O require application 2 hours before sun exposure).

F. Sunscreen should be reapplied every 2 to 3 hours and after swimming or sweating; otherwise, the duration of protection is reduced.

G. Products containing *para*-aminobenzoic acid need to be avoided by individuals allergic to benzocaine, sulfonamides, or thiazides.

H. Sunscreens can cause contact dermatitis and photosensitivity reactions.

The client should be informed that UV light is greatest between the hours of 10:00 a.m. and 4:00 p.m. and that sunglasses, protective clothing, and a hat should be worn to reduce the risk of skin damage from the sun.

VI. Medications to Treat Psoriasis (Box 44.4)

A. Description

1. Psoriasis is a chronic inflammatory disorder that has varying degrees of severity.
2. Treatment is based on the severity of symptoms and aims to suppress the proliferation of keratinocytes or suppress the activity of inflammatory cells.

B. Topical medications

1. Glucocorticoids
   - **a.** Used for mild psoriasis
   - **b.** Should not be applied to the face, groin, axilla, or genitalia, because the medication is readily absorbable, making the skin vulnerable to glucocorticoid-induced atrophy
2. Tazarotene
   - **a.** Is a vitamin A derivative
   - **b.** Local reactions include itching, burning, stinging, dry skin, and redness; other less common effects include rash, desquamation, contact dermatitis, inflammation, fissuring, and bleeding.
   - **c.** Sensitization to sunlight can occur, and the client should be instructed to use sunscreen and wear protective clothing.
   - **d.** Medication is usually applied once daily in the evening to dry skin.

BOX 44.4 Medications and Treatments for Psoriasis

Topical Medications
- Calcipotriene
- Coal tar
- Corticosteroids
- Keratolytics (topical salicylic acid; sulfur)
- Tazarotene

Systemic Medications
- Acitretin
- Cyclosporine
- Glucocorticoids
- Methotrexate

Systemic Biological Medications
- Adalimumab
- Brodalumab
- Etanercept
- Guselkumab
- Infliximab
- Ixekizumab
- Risankizumab
- Ustekinumab
- Secukinumab

Phototherapy
- Coal tar and ultraviolet B irradiation
- Photochemotherapy (psoralen and ultraviolet A therapy)

3. Calcipotriene
   - **a.** Is an analog of vitamin D
   - **b.** May take up to 1 to 3 weeks to produce a desired effect
   - **c.** Can cause local irritation; high-dose applications rarely have caused hypercalcemia.
4. Coal tar
   - **a.** Suppresses DNA synthesis, miotic activity, and cell proliferation
   - **b.** Has an unpleasant odor and may cause irritation, burning, and stinging; can also stain the skin and hair and increase sensitivity to sun
   - **c.** May increase risk for cancer development in high doses
5. Keratolytics
   - **a.** Soften scales and loosen the horny layer of the skin, resulting in minimal peeling to extensive desquamation
   - **b.** Salicylic acid: Can be absorbed systemically and can cause salicylism, which is characterized by dizziness and tinnitus, hyperpnea, and psychological disturbances; salicylic acid is not applied to large surface areas or open wounds because of the risk of systemic effects.
   - **c.** Sulfur: Promotes peeling and drying and is used to treat acne, dandruff, seborrheic dermatitis, and psoriasis

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

C. Systemic medications

1. Methotrexate

a. Reduces proliferation of epidermal cells

b. Can be toxic; causes gastrointestinal effects such as diarrhea and ulcerative stomatitis and bone marrow depression leading to blood dyscrasias

c. Can be hepatotoxic; hepatic function should be monitored during therapy

d. This medication is teratogenic; those persons of childbearing age should wait 3 months after discontinuation of the medication before becoming pregnant.

2. Acitretin

a. Inhibits keratinization, proliferation, and differentiation of cells; has antiinflammatory and immunomodulator actions; used for severe psoriasis and reserved for use in those who have not responded to safer medications

⚠ Acitretin is embryotoxic and teratogenic. It is contraindicated during pregnancy; pregnancy must be ruled out, and two reliable forms of contraception need to be implemented before the medication is started (a form of contraception must be implemented at least 1 month before treatment starts and be continued for at least 3 years after treatment is discontinued).

b. If pregnancy occurs during treatment with the medication, the medication is discontinued immediately and possible termination of the pregnancy is discussed.

c. Dermatological effects include hair loss, skin peeling, dry skin, rash, pruritus, and nail disorders; other effects include rhinitis from mucous membrane irritation, inflammation of the lips, dry mouth, dry eyes, nosebleed, gingivitis, stomatitis, bone and joint pain, and spinal disorders.

d. Can be hepatotoxic; can elevate triglyceride levels and reduce levels of high-density lipoprotein cholesterol

e. Should not be taken with alcohol, vitamin A supplementation, or tetracycline

f. Can take 2 to 6 months to receive full benefit

3. Cyclosporine

a. An immunosuppressant that inhibits proliferation of B and T cells

b. Can be toxic and cause kidney damage

c. Used for severe psoriasis and reserved for use in those who have not responded to safer medications

D. Systemic biological medications (clients should be tested for tuberculosis or other infections before initiation of medications)

1. These are injected into the skin or bloodstream; they block the altered immune system that is contributing to the psoriasis.

2. Some are tumor necrosis factor alpha-blockers; some bind to inflammation, causing proteins/interleukins; some are a human antibody that works against interleukins.

3. Adverse effects, which are generally not severe, include upper respiratory infections, abdominal pain, headache, rash, injection site reactions, and urinary tract infections; they may promote serious infections, including bacterial sepsis, invasive fungal infections, tuberculosis, and reactivation of hepatitis B; some medications increase the risk of developing lymphoma.

4. Contraindicated for persons with a history of certain cancers, severe or recurrent infections, heart failure, or demyelinating neurological diseases; given with caution to persons with numbness or tingling

5. The client should not receive any live virus vaccines, because the viruses used in some types of vaccines can cause infection in those with a weakened immune system; in addition, the PHCP needs to be informed if anyone in the household needs a vaccine.

6. The client should not receive the bacillus Calmette-Guérin (BCG) vaccine during the 1 year before taking or 1 year after taking the medication.

7. Clients should inform their PHCP if they are receiving phototherapy, have any other medical condition, are pregnant or plan to become pregnant, or are breast-feeding/ chest-feeding or plan to breast-feed or chest-feed. Safety with pregnancy has not been established with many of these medications.

E. Phototherapy

1. Coal tar and ultraviolet B (UVB) irradiation: Treatment that involves the application of coal tar for 8 to 10 hours; coal tar is washed off and the area is exposed to short-wave UV radiation (UVB).

2. Photochemotherapy (psoralen and ultraviolet A [UVA] therapy)

a. Combines the use of long-wave radiation (UVA) with oral methoxsalen (used in very specific cases; photosensitive medication)

b. Can cause pruritus, nausea, erythema; may accelerate the aging process of the skin; may increase the risk of skin cancer

VII. Acne Products (Box 44.5; Fig. 44.1)

A. Description

1. Acne lesions that are mild may be treated with nonpharmacological measures such as gentle cleansing 2 or 3 times daily (oil-based moisturizing products need to be avoided), dermabrasion, or comedo extraction.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 44.5 Acne Products

Topical Antibiotics
- Benzoyl peroxide
- Clindamycin and erythromycin
- Clindamycin/tretinoin combination gel
- Dapsone
- *Fixed-dose combinations:* Clindamycin/benzoyl peroxide and erythromycin/benzoyl peroxide

Topical Retinoids
- Adapalene
- Azelaic acid
- Tazarotene
- Tretinoin

Oral Medications
- Doxycycline
- Erythromycin
- Isotretinoin
- Minocycline
- Tetracycline

Hormonal Medications
- Oral contraceptives
- Spironolactone

FIG. 44.1 Acne vulgaris. **A,** Comedones with a few inflammatory pustules. **B,** Papulopustular acne. (From Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 404; Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. p. 864.)

2. Mild acne is usually treated pharmacologically with topical agents (antimicrobials and retinoids).
3. Moderate acne is usually treated with oral antibiotics and comedolytics.
4. Severe acne is usually treated with isotretinoin.
5. Hormonal medications may be prescribed to treat acne in some clients.
6. A type of combination therapy may be prescribed to treat acne.
7. Actions of the medications may include suppressing the growth of *Propionibacterium acnes*, reducing inflammation, promoting keratolysis, unplugging existing comedones and preventing their development, and normalizing hyperproliferation of epithelial cells within the hair follicles; some medications cause thinning of the skin, which facilitates penetration of other medications.
8. For topical applications: Site should be washed and allowed to dry completely before application; hands should be washed after application.
9. All topical products are kept away from the eyes, inside the nose, lips, mucous membranes, hair, and inflamed or denuded skin.

B. Topical antibiotic products
1. Benzoyl peroxide
   a. Can produce drying and peeling
   b. Severe local irritation (burning, blistering, scaling, swelling) may require reducing the frequency of applications.
   c. Some products may contain sulfites; monitor for serious allergic reactions.
2. Salicylic acid and sulfur/sulfacetamide can be used as well.
3. Clindamycin and erythromycin
   a. Both products are antibiotics that suppress the growth of *P. acnes.*
   b. Combination therapy with benzoyl peroxide prevents the emergence of resistant bacteria; fixed-dose combinations include clindamycin/benzoyl peroxide and erythromycin/benzoyl peroxide.
4. Dapsone: Side and adverse effects include oiliness, peeling, dryness, and erythema of the skin (oral form of medication is used to treat leprosy).

C. Topical retinoids
1. Tretinoin
   a. A derivative of vitamin A (vitamin A supplements should be discontinued during therapy)
   b. In addition to treating acne, it may be prescribed to reduce fine wrinkles, skin roughness, and mottled hyperpigmentation, as with age spots.
   c. Can cause localized side and adverse effects such as blistering, peeling, crusting, burning, and swelling of the skin
   d. Abrasive products and keratolytic products are discontinued before using tretinoin to decrease localized adverse effects.
   e. Instruct the client to apply a sunscreen with an SPF of 15 or greater and to wear protective clothing when outdoors due to sensitivity to UV light.
2. Adapalene: Similar to tretinoin and sensitizes the skin to UV light; adverse effects include burning and itching after application, redness, dryness, and scaling of the skin. Initially, it may worsen acne; benefits are seen in 8 to 12 weeks.
3. Tazarotene
   a. Is a derivative of vitamin A (vitamin A supplements should be discontinued during therapy)

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

   b. In addition to acne, it is used to treat wrinkles and psoriasis.
   c. Can cause itching, burning, and dry skin and sensitizes the skin to UV light
4. Azelaic acid can cause burning, itching, stinging, and redness of the skin; it can also cause hypopigmentation of the skin in clients with a dark complexion.

D. Oral antibiotics
1. Includes azithromycin, doxycycline, minocycline, tetracycline, erythromycin, trimethoprim-sulfamethoxazole, cephalosporins, penicillins
2. Improvement develops slowly with the use of oral antibiotics and may take 3 to 6 months for some improvement to be noted; after control of symptoms, the client is usually switched to a topical antibiotic.

E. Isotretinoin
1. Derivative of vitamin A (vitamin A supplements should be discontinued during therapy); in addition, the use of tetracyclines can increase the risk of adverse effects and should be discontinued before the use of isotretinoin.
2. Used to treat severe cystic acne; reserved for persons who have not responded to other therapies, including systemic antibiotics
3. Side and adverse effects include nosebleeds; inflammation of the lips or eyes; dryness or itching of the skin, nose, or mouth; pain, tenderness, or stiffness in the joints, bones, or muscles; and back pain.
4. Less common side and adverse effects include rash, hair loss, peeling of the skin, headache, and reduction in night vision.
5. Causes sensitization of the skin to UV light
6. The medication elevates triglyceride levels, which should be measured before and during therapy; alcohol consumption should be eliminated during therapy because alcohol could potentiate elevation of serum triglyceride levels.
7. The medication may cause depression in some clients; if depression occurs, the medication should be discontinued.

⚠ Isotretinoin is highly teratogenic and can cause fetal abnormalities. If prescribed, the client needs to follow strict rules of the iPLEDGE program. It must not be used if the client is pregnant.

F. iPLEDGE program
1. A risk management program that ensures that no person starting isotretinoin is pregnant and that no person taking this medication becomes pregnant; refer to American Academy of Dermatology Association at https://www.aad.org/public/diseases/acne-and-rosacea/isotretinoin-treatment-for-severe-acne
2. Access to the medication is controlled through a central automated system.
3. Strict rules must be followed by the client, PHCP prescribing the medication, pharmacist dispensing the medication, and wholesaler of the medication to ensure safety and to ensure that no person is pregnant on initiation of therapy or becomes pregnant while taking the medication.
4. Also see iPLEDGE® program at https://www.ipledgeprogram.com/iPledgeUI/home.u and iPledge REMS—About iPLEDGE at https://ipledgeprogram.com/#Main

G. Hormonal medications
1. Hormonal medications such as oral contraceptives and spironolactone may be prescribed to treat acne in some clients.
2. These medications decrease androgen activity, resulting in decreased production of sebum.
3. Spironolactone is teratogenic; therefore, contraception during its use is necessary.
4. Side and adverse effects of spironolactone include breast/chest tenderness, menstrual irregularities, and hyperkalemia.

VIII. Burn Products: (Box 44.6; refer to Chapter 70 for information on Caring for the Burn Client)

A. Silver sulfadiazine
1. Has broad spectrum of activity against gram-negative bacteria, gram-positive bacteria, and yeast. Decreases microbial colonization; does not improve wound healing
2. Silver is released slowly from the cream, which is selectively toxic to bacteria.
3. Used primarily to prevent sepsis in clients with burns
4. Not a carbonic anhydrase inhibitor; does not cause acidosis
5. Apply 1/16-inch film (keep burn covered at all times with silver sulfadiazine).
6. Side and adverse effects include rash and itching, blue-green or gray skin discoloration, leukopenia, and interstitial nephritis.
7. Monitor complete blood cell count, particularly the white blood cells, frequently; if leukopenia develops, the PHCP is notified (medication is usually discontinued).

B. Mafenide acetate
1. Water-soluble cream that is bacteriostatic for gram-negative and gram-positive organisms
2. Used to treat burns to reduce the bacteria present in avascular tissues

BOX 44.6 Burn Products

- Mafenide acetate
- Silver sulfadiazine
- Bacitracin topical ointment (first-degree burns only)
- Povidone-iodine
- Chlorhexidine as an antimicrobial skin cleanser

Telegram & Insta: NCLEX_RN_Edu

3. Diffuses through the devascularized areas of the skin and may precipitate **metabolic acidosis** with the client displaying hyperventilation; monitor blood gases and electrolytes.
4. Apply 1/16-inch (1.5 mm) film directly to the burn.
5. Side effects can include local pain and rash; medicate for pain before application.
6. Adverse effects include bone marrow depression, hemolytic anemia, and metabolic acidosis.
7. Keep the burn covered with mafenide acetate at all times.
8. Notify the PHCP if hyperventilation occurs; if acidosis develops, mafenide acetate is washed off the skin and usually discontinued for 1 to 2 days.

PRACTICE QUESTIONS

1. Salicylic acid is prescribed for a client with a diagnosis of psoriasis. The nurse monitors the client, knowing that which finding indicates the presence of systemic toxicity from this medication?
   1. Tinnitus
   2. Diarrhea
   3. Constipation
   4. Decreased respirations

2. The health education nurse plans to provide instructions to a group of clients regarding measures that will assist in preventing skin cancer. Which instructions would the nurse provide? **Select all that apply.**
   - ❑ 1. Sunscreen should be applied every 8 hours.
   - ❑ 2. Use sunscreen when participating in outdoor activities.
   - ❑ 3. Wear a hat, opaque clothing, and sunglasses when in the sun.
   - ❑ 4. Avoid sun exposure in the late afternoon and early evening hours.
   - ❑ 5. Examine your body monthly for any lesions that may be suspicious.

3. Silver sulfadiazine is prescribed for a client with a burn injury. Which laboratory finding requires the **need for follow-up** by the nurse?
   1. Glucose level of 99 mg/dL (5.65 mmol/L)
   2. Platelet level of 300,000 mm^3 (300 × 10^9/L)
   3. Magnesium level of 1.5 mEq/L (0.75 mmol/L)
   4. White blood cell count of 3000 mm^3 (3.0 × 10^9/L)

4. A burn client is receiving treatments of topical mafenide acetate to the site of injury. The nurse monitors the client, knowing that which finding indicates that a systemic effect has occurred?
   1. Hyperventilation
   2. Elevated blood pressure
   3. Local rash at the burn site
   4. Local pain at the burn site

5. Isotretinoin is prescribed for a client with severe acne. Before the administration of this medication, the nurse anticipates that which laboratory test will be prescribed?
   1. Potassium level
   2. Triglyceride level
   3. Hemoglobin A1c
   4. Total cholesterol level

6. A client with severe acne is seen in the clinic, and the primary health care provider (PHCP) prescribes isotretinoin. The nurse reviews the client's medication record and would collaborate with the PHCP about the prescription if the client is also taking which medication?
   1. Digoxin
   2. Phenytoin
   3. Vitamin A
   4. Furosemide

7. The nurse is applying a topical corticosteroid to a client with eczema. The nurse understands that it is safe to apply the medication to which body areas? **Select all that apply.**
   - ❑ 1. Back
   - ❑ 2. Axilla
   - ❑ 3. Eyelids
   - ❑ 4. Soles of the feet
   - ❑ 5. Palms of the hands

8. The clinic nurse is performing an admission assessment on a client and notes that the client is taking azelaic acid to treat acne. The nurse determines that which client complaint may be associated with the use of this medication?
   1. Itching
   2. Euphoria
   3. Drowsiness
   4. Frequent urination

9. Silver sulfadiazine is prescribed for a client with a partial-thickness burn, and the nurse provides teaching about the medication. Which statement made by the client indicates a **need for further teaching** about the treatments?
   1. "The medication is an antibacterial."
   2. "The medication will help heal the burn."
   3. "The medication should be applied directly to the wound."
   4. "The medication is likely to cause stinging every time it is applied."

10. The camp nurse asks the children preparing to swim in the lake if they have applied sunscreen. The nurse reminds the children that chemical sunscreens are **most effective** when applied at which times?
    1. Immediately before swimming
    2. 5 minutes before exposure to the sun
    3. Immediately before exposure to the sun
    4. At least 30 minutes before exposure to the sun

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 1

Rationale: Salicylic acid is absorbed readily through the skin, and systemic toxicity (salicylism) can result. Symptoms include tinnitus, dizziness, hyperpnea, and psychological disturbances. Constipation and diarrhea are not associated with salicylism.

Test-Taking Strategy: Focus on the **subject,** systemic toxicity. Noting the name of the medication will assist in directing you to the correct option if you can recall the toxic effects that occur with acetylsalicylic acid (aspirin).

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. p. 1286; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 681-682.

2. *Answer:* 2, 3, 5

Rationale: The client should be instructed to avoid sun exposure between the hours of brightest sunlight: 10 a.m. and 4 p.m. Sunscreen, a hat, opaque clothing, and sunglasses should be worn for outdoor activities. The client should be instructed to examine the body monthly for the appearance of any cancerous or precancerous lesions. Sunscreen should be applied 30 minutes to 1 hour before sun exposure and reapplied every 2 to 3 hours and after swimming or sweating; otherwise, the duration of protection is reduced.

Test-Taking Strategy: Focus on the **subject,** measures to prevent skin cancer. Read each option carefully. Noting the time frames in options 1 and 4 will assist in eliminating these options.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 468-469.

3. *Answer:* 4

Rationale: Silver sulfadiazine is used for the treatment of burn injuries. Adverse effects of this medication include rash and itching, blue-green or gray skin discoloration, leukopenia, and interstitial nephritis. The nurse would monitor a complete blood count, particularly the white blood cells, frequently for the client taking this medication. If leukopenia develops, the primary health care provider is notified and the medication is usually discontinued. The white blood cell count noted in option 4 is indicative of leukopenia. The other laboratory values are not specific to this medication and are also within normal limits.

Test-Taking Strategy: Note the **strategic words,** *need for follow-up*. Eliminate options 1, 2, and 3 because they are **comparable or alike** and are within normal limits. In addition, recall that leukopenia is an adverse effect requiring discontinuation of the medication.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 445; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 868.

4. *Answer:* 1

Rationale: Mafenide acetate is a carbonic anhydrase inhibitor and can suppress renal excretion of acid, thereby causing acidosis. Clients receiving this treatment should be monitored for signs of an acid-base imbalance (hyperventilation). If this occurs, the medication will probably be discontinued for 1 to 2 days. Options 3 and 4 describe local rather than systemic effects. An elevated blood pressure may be expected from the pain that occurs with a burn injury.

Test-Taking Strategy: Note the words *systemic effect*. Options 3 and 4 can be eliminated because they are **comparable or alike** and are local rather than systemic effects. From the remaining options, recall that the client in pain would likely have an elevated blood pressure. This should direct you to the correct option.

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. p. 1074; Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1071.

5. *Answer:* 2

Rationale: Isotretinoin can elevate triglyceride levels. Blood triglyceride levels should be measured before treatment and periodically thereafter until the effect on the triglycerides has been evaluated. There is no indication that isotretinoin affects potassium, hemoglobin A1c, or total cholesterol levels.

Test-Taking Strategy: Note the **subject,** laboratory values that should be monitored specifically for the client taking isotretinoin. Use knowledge about this medication to answer correctly. Recall that the medication can affect triglyceride levels in the client.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 421.

6. *Answer:* 3

Rationale: Isotretinoin is a metabolite of vitamin A and can produce generalized intensification of isotretinoin toxicity. Because of the potential for increased toxicity, vitamin A supplements should be discontinued before isotretinoin therapy. There are no contraindications associated with digoxin, phenytoin, or furosemide.

Test-Taking Strategy: Focus on the **subject,** the need to collaborate with the PHCP to ensure client safety. Recall that isotretinoin is a metabolite of vitamin A. Vitamin A is a fat-soluble vitamin; therefore, it is possible to develop toxic levels. This will direct you to the correct option.

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. pp. 1290-1291.

7. *Answer:* 1, 4, 5

Rationale: Topical corticosteroids can be absorbed into the systemic circulation. Absorption is higher from regions where the skin is especially permeable (scalp, axilla, face, eyelids, neck, perineum, genitalia) and lower from regions where permeability is poor (back, palms, soles). The nurse would avoid areas of higher absorption to prevent systemic absorption.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Focus on the **subject,** permeability and the potential for increased systemic absorption. Eliminate options 2 and 3, because these body areas are **comparable or alike** in terms of skin substance. From the remaining options, think about permeability of the skin area. This should direct you to the correct options.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. p. 1286.

8. *Answer:* 1
Rationale: Azelaic acid is a topical medication used to treat mild to moderate acne. Adverse effects include burning, itching, stinging, redness of the skin, and hypopigmentation of the skin in clients with a dark complexion. The effects noted in the other options are not specifically associated with this medication.
Test-Taking Strategy: Focus on the **subject,** an effect associated with the use of azelaic acid. Focusing on the name of the medication and recalling that acne medications commonly cause local irritation will direct you to the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 1372-1373.

9. *Answer:* 4
Rationale: Silver sulfadiazine is an antibacterial that has a broad spectrum of activity against gram-negative bacteria, gram-positive bacteria, and yeast. It is applied directly to the wound to assist in healing. It does not cause stinging when applied.
Test-Taking Strategy: Note the **strategic words,** *need for further teaching*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Recalling the characteristics of this medication will assist you in answering correctly.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 1373.

10. *Answer:* 4
Rationale: Sunscreens are most effective when applied at least 30 minutes before exposure to the sun so that they can penetrate the skin. All sunscreens should be reapplied after swimming or sweating.
Test-Taking Strategy: Knowledge that sunscreens need to penetrate the skin will assist in eliminating options 2 and 3. Next, noting the **strategic words,** *most effective*, will assist in directing you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 410.

UNIT VIII

Oncological and Hematological Problems of the Adult Client

Pyramid to Success

Pyramid Points focus on treatment modalities related to an oncological problem, such as pain management, internal and external radiation, radiotherapy, ablation, immunotherapy, and chemotherapy. In preparation for the NCLEX®, focus on the following oncological problems: skin cancer; leukemia; breast cancer; testicular cancer; stomach, bowel, and pancreatic cancers; bladder cancer; prostate cancer; and lung cancer. Particular attention is given to the nursing care related to these problems and treatment modalities, client adaptation to acceptance of diagnosis and associated lifestyle changes, and the impact of the treatment for the disorder on daily life. Also, concentrate on the complications related to chemotherapy, such as hematological problems, and the nursing measures required in monitoring for these complications and preventing life-threatening conditions, such as infection and bleeding. The psychosocial effects including altered body image and grief and loss are also a focus.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Discussing oncology-related consultations and referrals with the interprofessional health care team
Ensuring that advance directives are in the client's medical record
Ensuring advocacy related to the client's decisions
Ensuring that informed consent for treatments and procedures has been obtained
Handling hazardous and infectious materials related to radiation and chemotherapy safely
Implementing protective, standard, and other precautions
Maintaining medical and surgical asepsis and preventing infection
Prioritizing hypotheses based on client's preference and needs
Providing confidentiality regarding diagnosis
Upholding client rights

Health Promotion and Maintenance

Discussing expected body image changes related to chemotherapy and treatments
Providing client and family instructions regarding home care
Providing instructions regarding regular breast or testicular self-examinations
Respecting the client's lifestyle choices and generating solutions for necessary lifestyle changes
Teaching about health promotion programs regarding risks for cancer
Teaching about health screening measures for cancer

Psychosocial Integrity

Assessing the client's ability to cope, adapt, and/or solve problems during illness or stressful events
Assessing the concerns of the client with cancer and those who survived cancer
Assisting the client and family to cope with the alteration in body image
Discussing end-of-life and grief and loss issues related to death and the dying process
Mobilizing appropriate support and resource systems
Promoting a positive environment to maintain optimal quality of life
Respecting religious, spiritual, and cultural preferences

Physiological Integrity

Administering blood and blood products
Analyzing cues that indicate the need for follow-up care

Telegram & Insta: NCLEX_RN_Edu

Caring for central venous access devices and implanted ports
Caring for the client receiving chemotherapy or radiation therapy
Managing pain
Monitoring diagnostic tests and laboratory values, such as white blood cell, absolute neutrophil count, and platelet counts
Monitoring for expected and unexpected responses to radiation and chemotherapy
Protecting the client from the life-threatening adverse effects of treatments
Providing basic care and comfort
Providing nutrition
Recognizing cues that indicate a complication of the chemotherapy
Taking action in emergency situations

Telegram & Insta: NCLEX_RN_Edu

CHAPTER 45

Oncological and Hematological Problems

Contributor: Jessica Grimm, DNP, APRN, ACNP-BC, CNE

Telegram & Insta: NCLEX_RN_Edu

PRIORITY CONCEPTS Cellular Regulation; Safety

I. Cancer

A. Description

1. Cancer is a malignant neoplastic disorder that can involve all body organs with manifestations that vary according to the body system affected and type of tumor cells.
2. Cells lose their normal growth-controlling mechanism, and the growth of cells is uncontrolled.
3. Cancer produces serious health problems such as impaired immune and hematopoietic (blood-producing) function, altered gastrointestinal tract structure and function, motor and sensory deficits, and decreased respiratory function.

B. Metastasis (Box 45.1)

1. Cancer cells move from their original location to other sites.
2. Routes of metastasis
   - **a.** Local seeding: Distribution of shed cancer cells occurs in the local area of the primary tumor.
   - **b.** Bloodborne metastasis: Tumor cells enter the blood, which is the most common cause of cancer spread.
   - **c.** Lymphatic spread: Primary sites rich in lymphatics are more susceptible to early metastatic spread.

C. Cancer classification

1. Solid tumors: Associated with the organs from which they develop, such as breast cancer or lung cancer
2. Hematological cancers: Originate from blood cell–forming tissues, such as leukemias, lymphomas, and multiple myeloma

D. Grading and staging (Box 45.2)

1. Methods used to describe the tumor.
2. These methods describe the extent of the tumor, the extent to which malignancy has increased in size, the involvement of regional nodes, and metastatic development.
3. Grading a tumor classifies the cellular aspects of the cancer through microscopic evaluation of the level of differentiation in the cells. Grading is an indicator of tumor growth rate and spread.
4. Staging classifies the severity and clinical aspects of the cancer and degree of metastasis at diagnosis.

E. Factors that influence cancer development

1. Environmental factors
   - **a.** Chemical carcinogen: Factors include industrial chemicals, medications, alcohol, and tobacco.
   - **b.** Physical carcinogen: Factors include ionizing radiation (diagnostic and therapeutic x-rays) and ultraviolet radiation (sun, tanning beds, and germicidal lights), chronic irritation, and tissue trauma.
   - **c.** Viral carcinogen: Viruses capable of causing cancer are known as *oncoviruses*, such as Epstein-Barr virus, hepatitis B virus, and human papillomavirus.
   - **d.** *Helicobacter pylori* infection is associated with an increased risk of gastric cancer.
2. Lifestyle factors: Obesity, smoking, and diet (ingestion of preservatives, contaminants, additives, alcohol, and nitrates)
3. Genetic predisposition:
   - **a.** Factors include an inherited predisposition to specific cancers, inherited conditions associated with cancer, familial clustering, and chromosomal aberrations.
   - **b.** Tumor cell kinetics: loss of tumor suppression gene, proto-oncogenesis, loss or damage to DNA repair genes
4. Age: Advancing age is a significant risk factor for the development of cancer.

Telegram & Insta: NCLEX_RN_Edu

BOX 45.1 Common Sites of Metastasis

Bladder Cancer
- Lung
- Bone
- Liver
- Pelvic, retroperitoneal structures

Brain Tumors
- Central nervous system

Breast Cancer
- Bone
- Lung
- Brain
- Liver

Colorectal Cancer
- Liver

Lung Cancer
- Brain
- Liver
- Bone

Prostate Cancer
- Bone
- Spine
- Lung
- Liver
- Kidneys

Testicular Cancer
- Lung
- Bone
- Liver
- Adrenal glands
- Retroperitoneal lymph nodes

BOX 45.2 Grading and Staging

Grading

Grade I: Cells differ slightly from normal cells and are well differentiated (mild dysplasia).
Grade II: Cells are more abnormal and are moderately differentiated (moderate dysplasia).
Grade III: Cells are very abnormal and are poorly differentiated (severe dysplasia).
Grade IV: Cells are immature (anaplasia) and undifferentiated; cell of origin is difficult to determine.

Staging

Stage 0: Carcinoma in situ
Stage I: Tumor limited to the tissue of origin; localized tumor growth
Stage II: Limited local spread
Stage III: Extensive local and regional spread
Stage IV: Distant metastasis

BOX 45.3 Warning Signs of Cancer—CAUTION-US

- **C**hange in bowel or bladder habits
- **A**ny sore that does not heal
- **U**nusual bleeding or discharge
- **T**hickening or lump in breast or elsewhere
- **I**ndigestion
- **O**bvious change in wart or mole
- **N**agging cough or hoarseness
- **U**nexplained anemia
- **S**udden weight loss

Data from WebMD: *Understanding cancer—symptoms*. www.webmd.com/cancer/understanding-cancer-symptoms; and Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 240; https://www.theweek.in/webworld/features/lifestyle/seven-cancer-warning-signs-you-should-not-ignore.html

5. Immune function: The incidence of cancer is higher in immunosuppressed individuals, such as those with acquired immunodeficiency syndrome or organ transplant recipients who are taking immunosuppressive medications.

F. Prevention: Avoidance of known or potential carcinogens and avoidance or modification of the factors associated with the development of cancer cells

G. Early detection (Box 45.3)
1. Mammography
2. Papanicolaou (Pap) test
3. Rectal exams and stools for occult blood
4. Sigmoidoscopy, colonoscopy
5. Breast self-examination (BSE) and clinical breast examination
6. Testicular self-examination
7. Skin inspection
8. Routine assessment of warning signs of cancer (see Box 45.3)

II. Diagnostic Tests

A. Diagnostic tests to be performed depend on the suspected primary or metastatic site of the cancer; invasive procedures require **informed consent** (Box 45.4).

B. Biopsy
1. Description
   a. Biopsy is the definitive means of diagnosing cancer and provides histological proof of malignancy.
   b. Biopsy involves the surgical incision to obtain a small piece of tissue for microscopic examination.
2. Types
   a. Needle: Aspiration of cells
   b. Incisional: Removal of a wedge of suspected tissue from a larger mass

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 45.4 Diagnostic Tests

- Biopsy
- Bone marrow examination (particularly if a hematolymphoid malignancy is suspected)
- Chest radiograph
- Complete blood count (CBC)
- Computed tomography (CT); positron emission tomography (PET)
- Cytological studies (Papanicolaou test)
- Endoscopic examination: Upper gastrointestinal series, sigmoidoscopy, colonoscopy
- Evaluation of serum tumor markers (e.g., carcinoembryonic antigen and alpha-fetoprotein)
- Liver function studies
- Magnetic resonance imaging (MRI)
- Proctoscopic examination (including guaiac test for occult blood)
- Radiographic studies (mammography)
- Radioisotope scanning (liver, brain, bone, lung)
- Stool test for occult blood
- Tumor and genetic markers; molecular receptor status

   c. Excisional: Complete removal of the entire lesion
   d. Staging: Multiple needle or incisional biopsies in tissues where metastasis is suspected or likely (see Boxes 45.1 and 45.2)
3. Tissue examination
   a. Following excision, a frozen section or a permanent paraffin section is prepared to examine the specimen.
   b. The advantage of the frozen section is the speed with which the section can be prepared and the diagnosis made, because only minutes are required for this test.
   c. Permanent paraffin section takes about 24 hours; however, it provides clearer details than the frozen section.
4. Interventions
   a. The procedure usually is performed in an outpatient surgical setting.
   b. Prepare the client for the diagnostic procedure and provide postprocedure instructions.
   c. Ensure that informed consent has been obtained.

III. Pain Control

A. Causes of pain
1. Bone destruction, pathologic fractures, lytic lesions
2. Obstruction of an organ
3. Compression of peripheral nerves or spinal cord
4. Infiltration, distention of tissue
5. Inflammation, necrosis, tumor lysis
6. Psychological factors, such as fear or anxiety; a distress screening tool may be used to assess emotional health (see http://www.cancer.org/treatment/treatmentsandsideeffects/emotionalsideeffects/distressinpeoplewithcancer/distress-in-people-with-cancer-tools-to-measure-distress).
7. Treatment-associated ailments (surgical pain, neuropathic pain)

B. Interventions
1. Pain assessment includes location, intensity, quality, pattern, any relief measures.
2. Collaborate with other members of the health care team to develop a pain management program.
3. Most cancer pain can be managed successfully by giving adequate amounts of oral opioids around the clock.
4. Administer oral preparations if possible and if they provide adequate relief of pain; the transdermal or transmucosal route may also be prescribed.
5. Mild or moderate pain may be treated with salicylates, acetaminophen, and nonsteroidal antiinflammatory drugs (NSAIDs).
6. Severe pain is treated with opioids, such as codeine sulfate, morphine sulfate, methadone, and hydromorphone hydrochloride. Neuropathic pain may be treated with a variety of anticonvulsants and antidepressants, as well as opioids.
7. Subcutaneous injections and continuous intravenous (IV) infusions of opioids provide rapid pain control; equianalgesic comparison charts should be used when switching routes of administration of opioids.
8. Monitor vital signs and for side effects of medications.
9. Monitor for effectiveness of medications, and collaborate with the primary health care provider (PHCP) if medication is ineffective.
10. Provide nonpharmacological techniques of pain control such as relaxation, guided imagery, breathing techniques, biofeedback, massage, and heat-cold application.

! Assess the client's pain; pain is what the client describes or says that it is. Do not undermedicate the client with cancer who is in pain.

IV. Surgery

A. Description: Surgery is indicated to diagnose, stage, and treat certain types of cancer.

B. Prophylactic surgery
1. Prophylactic surgery is performed in clients with an existing premalignant condition or a known family history or genetic mutation that strongly predisposes the person to the development of cancer.

Telegram & Insta: NCLEX_RN_Edu

2. An attempt is made to remove the tissue or organ at risk and thus prevent the development of cancer.

C. Curative surgery: All gross and microscopic tumor is removed or destroyed; this approach is most effective when tumors are small and localized.

D. Control (cytoreductive or "debulking") surgery
   1. Control surgery is a debulking procedure that consists of removing a large portion of a locally invasive tumor, such as advanced ovarian cancer.
   2. Surgery decreases the number of cancer cells; therefore, it may increase the chance that other therapies will be successful.

E. Palliative surgery
   1. Palliative surgery is performed to improve quality of life during the survival time.
   2. Palliative surgery is performed to reduce pain, relieve airway obstruction, relieve obstructions in the gastrointestinal or urinary tract, relieve pressure on the brain or spinal cord, prevent hemorrhage, remove infected or ulcerated tumors, or drain abscesses.

F. Reconstructive or rehabilitative surgery is performed to improve quality of life by restoring maximal function and appearance, such as breast reconstruction after mastectomy.

G. Adverse effects of surgery
   1. Pain, infection, bleeding, thromboembolism
   2. Reduced function as a result of organ loss
   3. Loss of function of a specific body part or loss of a body part
   4. Scarring or disfigurement
   5. Grieving about altered body image or imposed change in lifestyle. Clients may need supportive care and help in adapting to their new normal.

V. Chemotherapy

A. Description
   1. Chemotherapy kills or inhibits the reproduction of neoplastic cells and kills normal cells.
   2. The effects are systemic because chemotherapy is usually administered systemically.
   3. Normal cells most profoundly affected include those of the skin, hair, and lining of the gastrointestinal tract; spermatocytes; and hematopoietic cells.
   4. Usually, several chemotherapy and biotherapy agents are used in combination (combination therapy) to increase the therapeutic response.
   5. Combination chemotherapy is planned by the PHCP so that medications with overlapping toxicities and **nadirs** (the time during which bone marrow activity and white blood cell counts are at their lowest) are not administered at or near the same time; this will minimize immunosuppression.
   6. Chemotherapy may be combined with other treatments, such as surgery and radiation.

B. Common side effects include fatigue, alopecia, nausea and vomiting, mucositis, skin changes, and myelosuppression (neutropenia, anemia, and thrombocytopenia).

C. See Chapter 46 for information regarding care of the client receiving chemotherapy.

VI. Radiation Therapy

A. Description
   1. Radiation therapy destroys cancer cells, with minimal exposure of normal cells to the damaging effects of radiation. The damaged cells die or become unable to divide.
   2. Radiation therapy is effective on tissues directly within the path of the radiation beam.
   3. Side effects include local skin changes and irritation, alopecia (hair loss), fatigue (most common side effect of radiation), and altered taste sensation; the effects vary according to the site of treatment.
   4. External beam radiation (also called *teletherapy*) and internal radiation (also called *brachytherapy*) are the types of radiation therapy most commonly used to treat cancer.

B. External beam radiation (teletherapy): The actual radiation source is external to the client.
   1. Instruct the client regarding self-care of the skin (Box 45.5).
   2. The client does not emit radiation and does not pose a hazard to anyone else.

C. Brachytherapy
   1. The radiation source comes into direct, continuous contact with tumor tissues for a specific time.
   2. The radiation source is within the client; for a period of time, the client emits radiation and can pose a hazard to others.
   3. The radioactive source can be in the form of capsules, seeds, microspheres, or ribbons about the size of a grain of rice.
   4. Brachytherapy includes an unsealed source or a sealed source of radiation.
   5. Brachytherapy can be used by itself or in conjunction with surgery, chemotherapy, or external beam radiation.
   6. Types
      a. Permanent brachytherapy: The radioactive elements are inserted and remain in the client for weeks or months; they do not usually cause discomfort and over time lose their radioactivity.
      b. Temporary brachytherapy: The radioactive material is removed after a few minutes or a few days; after removal, there is no remaining radioactivity in the body.
      c. High-dose rate implants (HDR): In place for only 10 to 20 minutes due to the high radioactivity; may require two treatments a day over 2 to 5 days or once a week for up to 5 weeks

Telegram & Insta: NCLEX_RN_Edu

BOX 45.5 Client Education Guide: Radiation Therapy for Cancer

- Wash the irradiated area gently each day with warm water alone or with mild soap and water.
- Use the hand rather than a washcloth to wash the area.
- Rinse soap thoroughly from the skin.
- Take care not to remove the markings that indicate exactly where the beam of radiation is to be focused.
- Dry the irradiated area with patting motions rather than rubbing motions (avoid friction to the area being treated); use a clean, soft towel or cloth.
- Use no powders, ointments, lotions, or creams on the skin at the radiation site unless they are prescribed by the radiologist.
- Wear soft clothing over the skin at the radiation site.
- Avoid wearing belts, buckles, straps, or any type of clothing that binds or rubs the skin at the radiation site.
- Avoid exposure of the irradiated area to the sun.
- When outdoors, stay covered with clothing or stay under awnings, umbrellas, and other forms of shade during the times when the sun's rays are most intense (between 10 a.m. and 4 p.m.).
- Try to go outdoors in the early morning or evening to avoid more intense sun rays.
- Avoid heat exposure.

d. Low-dose rate implants (LDR): Generally require a hospital stay. It may be up to 2 days until the radioactive material is removed.

7. Unsealed radiation source
   - **a.** Administration is via the oral or IV route or by instillation into body cavities.
   - **b.** The source is not confined completely to one body area, and it enters body fluids and eventually is eliminated via various excreta, which are radioactive and harmful to others. Most of the source is eliminated from the body within 48 hours; then neither the client nor the excreta is radioactive or harmful.
8. Sealed radiation source (see Clinical Judgment: Take Action Box) (Box 45.6)
   - **a.** A sealed, temporary or permanent radiation source (solid implant) is implanted within the tumor target tissues.
   - **b.** The client emits radiation while the implant is in place, but the excreta are not radioactive.
9. Removal of sealed radiation sources
   - **a.** The client is not radioactive after removal.
   - **b.** Inform the client that cancer is not contagious.
   - **c.** Inform the client to follow the PHCP's prescription regarding resumption of sexual intercourse if the implant was cervical or vaginal.
   - **d.** Advise the client who had a cervical or vaginal implant to notify the PHCP if any of the following occurs: severe diarrhea, frequent urination, urethral burning for more than 24 hours, hematuria, heavy vaginal bleeding, extreme fatigue, abdominal pain, fever over 100° F (38° C), or other signs of infection.

BOX 45.6 Care of the Client with a Sealed Radiation Implant

- Place the client in a private room with a private bath.
- Place a radiation precaution sign on the client's door.
- Keep the room door closed as much as is possible.
- Organize nursing tasks to minimize exposure to the radiation source.
- Nursing assignments to a client with a radiation implant should be rotated.
- Limit time to 30 minutes per care provider per shift.
- Wear a dosimeter film badge to measure radiation exposure.
- Lead shielding may be used to reduce exposure to radiation.
- Never touch a radioactive source with bare hands; if seen, deposit the radioactive source in the lead container kept in the client's room.
- The nurse should never care for more than one client with a radiation implant at one time.
- Do not allow a pregnant nurse to care for the client.
- If a person is attempting to conceive, that person would not care for the client.
- Do not allow children younger than 16 years or a pregnant individual to visit the client.
- Limit visitors to 30 minutes per day; visitors should be at least 6 feet from the source.
- Save bed linens and dressings until the source is removed; then dispose of the linens and dressings in the usual manner.
- Other equipment can be removed from the room at any time.

CLINICAL JUDGMENT: TAKE ACTION

The nurse is caring for a hospitalized client who has a sealed radiation implant to treat cervical cancer. During morning care, the nurse turns the client to the side and sees the radiation seed lying under the client. The nurse takes the following actions:

- Encourages the client to lie still.
- Uses a long-handled forceps to retrieve the radioactive source.
- Deposits the radioactive source in a lead container.
- Contacts the radiation oncologist.
- Does not allow others to enter the room until the source is secured.
- Documents the occurrence and the actions taken.

VII. Hematopoietic Stem Cell Transplantation

A. Description

1. Bone marrow transplantation (BMT) and peripheral blood stem cell transplantation (PBSCT) are procedures that replace stem cells that have been destroyed by high doses of chemotherapy and/or radiation therapy.

Telegram & Insta: NCLEX_RN_Edu

2. BMT and PBSCT are most commonly used in the treatment of leukemia and lymphoma but are also used to treat other cancers, such as neuroblastoma and multiple myeloma.
3. The goal of treatment is to rid the client of all leukemic or other malignant cells through treatment with high doses of chemotherapy and whole-body irradiation.
4. Because these treatments are damaging to bone marrow cells, without the replacement of blood-forming stem cell function through transplantation, the client would die of infection or hemorrhage.

B. Types of donor stem cells
1. Allogeneic: Stem cell donor is usually a sibling, a parent with a similar tissue type, or a person who is not related to the client (unrelated donor).
2. Syngeneic: Stem cells are from an identical twin.
3. Autologous
   a. Autologous donation is the most common type.
   b. Clients receive their own stem cells.
   c. Stem cells are harvested during disease remission and are stored frozen to be reinfused later.

C. Procedure
1. Harvest
   a. The stem cells used in PBSCT come from the bloodstream in a 4- to 6-hour process called *apheresis* or *leukapheresis* (the blood is removed through a central venous catheter, and an apheresis machine removes the stem cells and returns the remainder of the blood to the donor).
   b. In BMT, marrow is harvested through multiple aspirations from the iliac crest to retrieve sufficient bone marrow for the transplant.
   c. Marrow from the client is filtered for residual cancer cells.
   d. Allogeneic marrow is transfused immediately; autologous marrow is frozen for later use (cryopreservation).
   e. Harvesting is done before the initiation of the conditioning regimen.
2. *Conditioning* refers to an immunosuppression therapy regimen used to eradicate all malignant cells, provide a state of immunosuppression, and create space in the bone marrow for the engraftment of the new marrow.
3. Transplantation
   a. Stem cells are administered through the client's central line in a manner similar to that for a blood transfusion.
   b. Stem cells may be administered by IV infusion or by IV push directly into the central line.
4. Engraftment
   a. The transfused stem cells move to the marrow-forming sites of the recipient's bones.
   b. Engraftment occurs when the white blood cell (WBC), erythrocyte, and platelet counts begin to rise.
   c. When successful, the engraftment process takes 2 to 5 weeks.

D. Posttransplantation period: Infection, bleeding, or neutropenia and thrombocytopenia are major concerns until engraftment occurs.

⚠ During the posttransplantation period, the client remains without any natural immunity until the donor stem cells begin to proliferate and engraftment occurs.

E. Complications
1. Failure to engraft: If the transplanted stem cells fail to engraft, the client will die unless another transplantation is attempted and is successful.
2. Graft-versus-host disease in allogeneic transplants
   a. Although the recipient cannot recognize the donated stem cells as foreign or nonself because of the total immunosuppression, the immune-competent cells of the donor recognize the recipient's cells as foreign and mount an immune offense against them.
   b. Graft-versus-host disease is managed cautiously with immunosuppressive agents to avoid suppressing the new immune system to such an extent that the client becomes more susceptible to infection, or the transplanted cells stop engrafting.
3. Hepatic veno-occlusive disease
   a. The disease involves occlusion of the hepatic venules by thrombosis or phlebitis.
   b. Signs include right upper quadrant abdominal pain, jaundice, ascites, weight gain, and hepatomegaly.
   c. Early detection is critical because there is no known way to open the hepatic vessels.
   d. The client will be treated with fluids and supportive therapy.

VIII. Skin Cancer (see Chapter 43)

IX. Leukemia (Box 45.7)

A. Description
1. Leukemias are a group of hematological malignancies involving abnormal overproduction of leukocytes, usually at an immature stage, in the bone marrow.
2. The two major types of leukemia are lymphocytic (involving abnormal cells from the lymphoid pathway) and myelocytic or myelogenous

Telegram & Insta: NCLEX_RN_Edu

BOX 45.7 Classification of Leukemia

Acute Lymphocytic Leukemia
- Mostly lymphoblasts present in bone marrow
- Age of onset is younger than 15 years.

Acute Myelogenous Leukemia
- Mostly myeloblasts present in bone marrow
- Age of onset is between 15 and 39 years.

Chronic Myelogenous Leukemia
- Mostly granulocytes present in bone marrow
- Age of onset is in the fourth decade.

Chronic Lymphocytic Leukemia
- Mostly lymphocytes present in bone marrow
- Age of onset is after 50 years.

References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for inter-professional collaborative care*. (10th ed.). St. Louis: Saunders. p. 803.

Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 638.

(involving abnormal cells from the myeloid pathways).

3. Leukemia may be acute, with a sudden onset, or chronic, with a slow onset and persistent symptoms over a period of years.
4. Leukemia affects the bone marrow, causing anemia, leukopenia, the production of immature cells, thrombocytopenia, and a decline in immunity.
5. The cause is unknown and appears to involve genetically damaged cells, leading to the transformation of cells from a normal state to a malignant state.
6. Risk factors include genetic, viral, immunological, and environmental factors and exposure to radiation, chemicals, and medications, such as previous chemotherapy.

B. Assessment
1. History of infections and illnesses
2. Anorexia, fatigue, weakness, weight loss
3. Anemia (decreased hemoglobin and hematocrit levels)
   a. Palpitations, tachycardia, orthostatic hypotension
   b. Pallor and dyspnea on exertion
4. Decreased platelet count
   a. Overt bleeding (nosebleeds, gum bleeding, rectal bleeding, hematuria, increased menstrual flow) and occult bleeding (e.g., as detected in a fecal occult blood test)
   b. Ecchymoses, petechiae
   c. Prolonged bleeding after minor abrasions or lacerations
5. Elevated temperature
6. Enlarged lymph nodes, spleen, liver
7. Headache
8. Bone pain and joint swelling
9. Normal, elevated, or reduced WBC count
10. Positive bone marrow biopsy identifying leukemic blast–phase cells

C. Infection
1. Infection can occur through autocontamination or cross-contamination. The WBC count may be extremely low during the period of greatest bone marrow depression, known as the *nadir*.
2. Common sites of infection are the skin, respiratory tract, and gastrointestinal tract.
3. Initiate protective isolation procedures.
4. Ensure frequent and thorough handwashing by the client, family, and health care providers.
5. Staff and visitors with known infections or exposure to communicable diseases should avoid contact with the client.
6. Use strict aseptic technique for all procedures.
7. Keep supplies for the client separate from supplies for other clients; keep frequently used equipment in the room for the client's use only.
8. Limit the number of staff entering the client's room to reduce the risk of cross-infection.
9. Maintain the client in a private room with the door closed.
10. Place the client in a room with high-efficiency particulate air filtration or a laminar airflow system if possible.
11. Reduce exposure to environmental organisms by eliminating fresh or raw fruits and vegetables (neutropenic diet) from the diet; eliminate fresh flowers and live plants from the client's room, and avoid leaving standing water in the client's room.
12. Be sure that the client's room is cleaned daily.
13. Assist the client with daily bathing, using an antimicrobial soap.
14. Assist the client to perform oral hygiene frequently.
15. Initiate a bowel program to prevent constipation and prevent rectal trauma.
16. Avoid invasive procedures such as injections, insertion of rectal thermometers, and urinary catheterization.
17. Change wound dressings daily, and inspect the wounds for redness, swelling, or drainage.
18. Assess the urine for cloudiness and other characteristics of infection.
19. Assess skin and oral mucous membranes for signs of infection (Box 45.8).
20. Auscultate lung sounds, and encourage the client to cough and deep-breathe.
21. Monitor temperature, pulse, respirations, and blood pressure; also monitor for pain.

Telegram & Insta: NCLEX_RN_Edu

BOX 45.8 Mouth Care for the Client with Mucositis

- Inspect the mouth daily, including the roof, under the tongue, between the teeth, and cheeks.
- Offer complete mouth care before and after every meal and at bedtime.
- Brush the teeth and tongue with a soft-bristled toothbrush or sponges.
- Provide mouth rinses every 12 hours with the prescribed solution.
- Be sure that dentures are kept clean and that they fit well.
- Administer topical anesthetic agents to mouth sores as prescribed.
- Avoid the use of alcohol- or glycerin-based mouthwashes or swabs because they are irritating to the mucosa.
- Offer soft foods that are cool to warm in temperature rather than foods that are hard or spicy or cold or hot.
- Seek treatment if mouth sores are present.

22. Monitor WBC and neutrophil counts.
23. Notify the PHCP if signs of infection are present, and prepare to obtain specimens for culture of the blood, open lesions, urine, and sputum; chest radiograph may also be prescribed.
24. Administer prescribed antibiotic, antifungal, and antiviral medications.
25. Instruct the client to avoid crowds and those with infections.
26. Instruct the client about a neutropenic diet and in food safety when preparing meals.
27. Instruct the client not to drink perishable liquids that have been standing at room temperature for longer than an hour.
28. Instruct the client to avoid activities that expose the client to infection, such as changing a pet's litter box or working with houseplants or in the garden.
29. Instruct clients that neither they nor their household contacts should receive **vaccines** with a live virus. For a list of live virus vaccines see: https://www.hhs.gov/immunization/basics/types/index.html

Infection is a major cause of death in the immunosuppressed client.

D. Bleeding

1. During the period of greatest bone marrow suppression (the nadir), the platelet count may be extremely low.
2. The client is at risk for bleeding when the platelet count falls below 50,000 mm^3 (50×10^9/L), and spontaneous bleeding frequently occurs when the platelet count is lower than 20,000 mm^3 (20×10^9/L).
3. Clients with platelet counts lower than 20,000 mm^3 (20×10^9/L) may need a **platelet transfusion.**
4. For clients with anemia and fatigue, **packed red blood cells** may be prescribed.
5. Monitor laboratory values.
6. Examine the client for signs and symptoms of bleeding, such as petechiae; examine all body fluids and excrement for the presence of blood.
7. Handle the client gently; use caution when taking blood pressures to prevent skin injury.
8. Monitor for signs of internal hemorrhage (e.g., pain, rapid and weak pulse, increased abdominal girth, abdomen guarding, change in mental status).
9. Provide soft foods that are cool to warm to avoid oral mucosa damage.
10. Avoid injections, if possible, to prevent trauma to the skin and bleeding; apply firm and gentle pressure to a needlestick site for at least 5 minutes, or longer if needed.
11. Pad side rails and sharp corners of the bed and furniture.
12. Avoid rectal suppositories, enemas, and thermometers.
13. Instruct client to take a stool softener to avoid straining from a bowel movement.
14. If the client is menstruating, count the number of pads or tampons used.
15. Administer blood products as prescribed.
16. Instruct the client to use a soft toothbrush and avoid dental floss.
17. Instruct the client to use only an electric razor for shaving.
18. Instruct the client to avoid blowing the nose.
19. Discourage the client from engaging in activities involving the use of sharp objects; contact sports also need to be avoided.
20. Instruct the client to avoid using NSAIDs and products that contain aspirin.
21. Instruct the client to consult with their oncologist before having dental work performed.

E. Fatigue and nutrition

1. Assist the client in selecting a well-balanced diet.
2. Provide small, frequent meals (high calorie, high protein, high carbohydrate) that require little chewing to reduce energy expenditure at mealtimes.
3. Assist the client in self-care and mobility activities.
4. Allow adequate rest periods during care.
5. Do not perform activities unless they are essential; assist the client in scheduling important or pleasurable activities during periods of highest energy.
6. Administer blood products for anemia as prescribed.

Telegram & Insta: NCLEX_RN_Edu

F. Additional interventions
1. Chemotherapy
   a. Induction therapy is aimed at achieving a rapid, complete remission of all manifestations of the disease.
   b. Consolidation therapy is administered early in remission with the aim of curing.
   c. Maintenance therapy may be prescribed for months or years after successful induction and consolidation therapy; the aim is to maintain remission.
2. Administer antibiotic, antibacterial, antiviral, and antifungal medications as prescribed.
3. Administer colony-stimulating factors as prescribed.
4. Administer blood replacements as prescribed.
5. Maintain infection and bleeding precautions.
6. Prepare the client for transplantation if indicated.
7. Instruct the client in appropriate home care measures.
8. Provide psychosocial support and support services for home care.

X. Lymphoma: Hodgkin's Disease

A. Description
1. The disease usually involves lymph nodes, tonsils, spleen, and bone marrow and is characterized by the presence of Reed-Sternberg cells in the nodes.
2. Lymphomas, classified as Hodgkin's and non-Hodgkin's depending on the cell type, are characterized by abnormal proliferation of lymphocytes.
3. Hodgkin's disease is a malignancy of the lymph nodes that originates in a single lymph node or a chain of nodes.
4. Metastasis occurs to other, adjacent lymph structures and eventually invades nonlymphoid tissue.
5. Possible causes include viral infections; clients treated with combination chemotherapy for Hodgkin's disease have a greater risk of developing acute leukemia and non–Hodgkin's lymphoma, among other secondary malignancies.
6. Prognosis depends on the stage of the disease.
7. Can affect any age group; however, it appears to peak in teens and young adults and adults in their 50s and 60s.

B. Assessment
1. Fever, chills, tachycardia
2. Malaise, fatigue, and weakness
3. Night sweats
4. Loss of appetite and significant weight loss
5. Anemia and thrombocytopenia
6. Enlarged lymph nodes, spleen, and liver
7. Positive biopsy of lymph nodes, with cervical nodes most often affected first
8. Presence of Reed-Sternberg cells in nodes
9. Positive computed tomography (CT) scan of the liver and spleen
10. Position emission tomography (PET) to stage the disease and monitor response to therapy.

C. Interventions
1. For earlier stages (stages I and II), without mediastinal node involvement, the treatment of choice is extensive external radiation of the involved lymph node regions.
2. With more extensive disease, radiation and multiagent chemotherapy are used.
3. Monitor for side effects related to chemotherapy or radiation therapy.
4. Monitor for signs of infection and bleeding.
5. Maintain infection and bleeding precautions.
6. Discuss the possibility of sterility with the client receiving chemotherapy and/or radiation, and inform the client of fertility options such as sperm banking.

XI. Multiple Myeloma

A. Description
1. A malignant proliferation of plasma cells within the bone
2. Excessive numbers of abnormal plasma cells invade the bone marrow and ultimately destroy bone; invasion of the lymph nodes, spleen, and liver occurs.
3. The abnormal plasma cells produce an abnormal antibody (myeloma protein or the Bence Jones protein) found in the blood and urine.
4. Multiple myeloma causes decreased production of immunoglobulin and antibodies and increased levels of uric acid and calcium, which can lead to kidney failure.
5. The disease typically develops slowly, and the cause is unknown.
6. Risk factors include a diagnosis of monoclonal gammopathy of undetermined significance (MGUS).

B. Assessment
1. Bone (skeletal) pain, especially in the ribs, spine, and pelvis
2. Weakness and fatigue
3. Recurrent infections
4. Anemia
5. Urinalysis shows Bence Jones proteinuria and elevated total serum protein level.
6. Osteoporosis (bone loss and the development of pathological fractures)
7. Thrombocytopenia and leukopenia
8. Elevated calcium and uric acid levels
9. Kidney failure

Telegram & Insta: NCLEX_RN_Edu

10. Spinal cord compression and paraplegia
11. Bone marrow aspiration shows an abnormal number of immature plasma cells.

The client with multiple myeloma is at risk for pathological fractures. Therefore, provide skeletal support during moving, turning, and ambulating, and provide a hazard-free environment.

C. Interventions
1. Administer chemotherapy as prescribed.
2. Provide supportive care to control symptoms and prevent complications, especially bone fractures, hypercalcemia, kidney failure, and infections.
3. Maintain neutropenic and bleeding precautions as necessary.
4. Monitor for signs of bleeding, infection, and skeletal fractures.
5. Encourage the consumption of at least 2 L of fluids per day to offset potential problems associated with hypercalcemia, hyperuricemia, and proteinuria, and encourage additional fluid as indicated and tolerated.
6. Monitor for signs of kidney failure. Collect 24-hour urine as prescribed.
7. Encourage ambulation to prevent renal problems and to slow down bone resorption.
8. Administer IV fluids and diuretics as prescribed to increase renal excretion of calcium.
9. Administer blood transfusions as prescribed for anemia.
10. Administer analgesics as prescribed, and provide nonpharmacological therapies to control pain.
11. Administer antibiotics as prescribed for infection.
12. Prepare the client for local radiation therapy if prescribed.
13. Instruct the client in home care measures and the signs and symptoms of infection.
14. Administer bisphosphonate medications as prescribed to slow bone damage and reduce pain and risk of fractures.

XII. Testicular Cancer

A. Description
1. Testicular cancer arises from germinal epithelium from the sperm-producing germ cells or from nongerminal epithelium from other structures in the testicles.
2. Testicular cancer most often occurs between the ages of 15 and 40 years; a higher risk is present if there is a family history of testicular cancer.
3. The cause of testicular cancer is unknown, but a history of undescended testicle (cryptorchidism) and genetic predisposition have been associated with testicular tumor development.

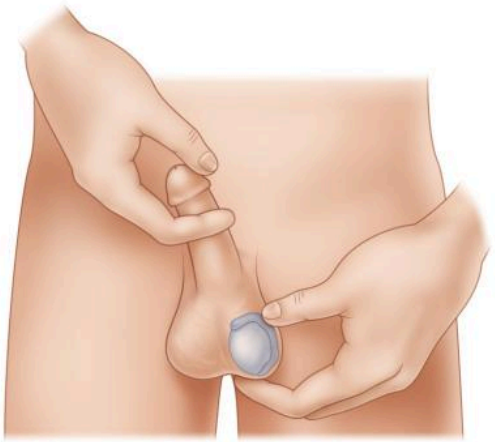

FIG. 45.1 Testicular self-examination. The best time to perform this examination is right after a shower when your scrotal skin is moist and relaxed, making the testicles easy to feel. First, gently lift each testicle. Each one should feel like an egg, firm but not hard, and smooth with no lumps. Then, using both hands, place your middle fingers on the underside of each testicle and your thumbs on top. Gently roll the testicle between the thumb and fingers to feel for any lumps, swelling, or mass. If you notice any changes from one month to the next, notify your primary health care provider.

4. Metastasis occurs to the lung, liver, bone, and adrenal glands via the blood and to the retroperitoneal lymph nodes via lymphatic channels.

B. Early detection: Perform monthly testicular self-examination (Fig. 45.1).
1. Performing testicular self-examination: Perform monthly; a day of the month is selected, and the examination is performed on the same day each month.
2. Client instructions (see Fig. 45.1)

C. Assessment
1. Painless testicular swelling occurs.
2. "Dragging" or "pulling" sensation is experienced in the scrotum.
3. Palpable lymphadenopathy, abdominal masses, and gynecomastia may indicate metastasis.
4. Late signs include back or bone pain and respiratory symptoms.

D. Interventions
1. Administer chemotherapy as prescribed.
2. Prepare the client for radiation therapy as prescribed.
3. Prepare the client for unilateral orchiectomy, if prescribed, for diagnosis and primary surgical management or radical orchiectomy (surgical removal of the affected testis, spermatic cord, and regional lymph nodes).
4. Prepare the client for retroperitoneal lymph node dissection, if prescribed, to stage the disease and reduce tumor volume so that chemotherapy and radiation therapy are more effective.
5. Discuss reproduction, sexuality, and fertility information and options with the client.
6. Identify reproductive options such as sperm storage, donor insemination, and adoption.

Telegram & Insta: NCLEX_RN_Edu

BOX 45.9 Premalignant Cancers: Stages of Cervical Intraepithelial Neoplasia

Stage I: Mild dysplasia
Stage II: Moderate dysplasia
Stage III: Severe dysplasia to carcinoma in situ

BOX 45.10 Treatment for Cervical Cancer

Nonsurgical
- Chemotherapy
- Cryosurgery
- External radiation
- Internal radiation implants (intracavitary)
- Laser therapy

Surgical
- Loop electrosurgical excision procedure (LEEP)
- Radical trachelectomy (radical cervicectomy)
- Conization
- Hysterectomy
- Pelvic exenteration

Note: Internal radiation therapy is used for clients for whom surgery is not an option.

E. Postoperative interventions
1. Monitor for signs of bleeding and wound infection; antibiotics may be administered to prevent wound infection.
2. Monitor intake and output.
3. Provide and explain pain management methods; to reduce swelling in the first 48 hours, apply an ice pack with an intervening protective layer of cloth.
4. Notify the PHCP if chills, fever, increasing pain or tenderness at the incision site, or drainage from the incision occurs.
5. After the orchiectomy, instruct the client to avoid heavy lifting and strenuous activity for the length of time prescribed by the PHCP.
6. Instruct the client to perform a monthly testicular self-examination on the remaining testicle (see Fig. 45.1).
7. Inform the client that sutures will be removed approximately 7 to 10 days after surgery and that follow-up is important.

XIII. Cervical Cancer

A. Description
1. Preinvasive cancer is limited to the cervix (Box 45.9).
2. Invasive cancer is in the cervix and other pelvic structures.
3. Metastasis usually is confined to the pelvis, but distant metastasis occurs through lymphatic spread.
4. Premalignant changes are described on a continuum from dysplasia, which is the earliest premalignancy change, to **carcinoma in situ,** the most advanced premalignant change.
5. Prevention includes the human papillomavirus vaccine (HPV). See the Centers for Disease Control and Infection (CDC) information on this vaccine at https://www.cdc.gov/std/hpv/stdfact-hpv-vaccine-young-women.htm

B. Risk factors
1. Human papillomavirus (HPV) infection (vaccination against HPV is effective to avoid HPV infection, and thus cervical cancer)
2. Family history of cervical cancer
3. Cigarette smoking, both active and passive
4. Reproductive behavior, including early first intercourse (before age 17 years), multiple sex partners, or partners with multiple sex partners
5. Being immunocompromised
6. Obesity
7. Long-term use of oral contraceptives
8. Multiple full-term pregnancies
9. First full-term pregnancy earlier than age 17
10. Multiparity (multiple birth)
11. Screening via regular gynecological examinations and Pap test, with treatment of precancerous abnormalities, decreases the incidence and mortality of cervical cancer. For current guidelines for screening according to the CDC see https://www.cdc.gov/cancer/cervical/basic_info/screening.htm and https://www.cdc.gov/media/releases/2013/p0103_pap_test.html

C. Assessment
1. Painless vaginal postmenstrual and postcoital bleeding
2. Foul-smelling or serosanguineous vaginal discharge
3. Pelvic, lower back, leg, or groin pain
4. Anorexia and weight loss
5. Leakage of urine and feces from the **vagina**
6. Dysuria
7. Hematuria
8. Cytological changes on Pap test

D. Interventions (Box 45.10)

E. Laser therapy
1. Laser therapy is used when all boundaries of the lesion are visible during colposcopic examination.
2. Energy from the beam is absorbed by fluid in the tissues, causing them to vaporize.
3. Minimal bleeding is associated with the procedure.
4. Slight vaginal discharge is expected after the procedure, and healing occurs in 6 to 12 weeks.
5. The disadvantage is that no specimen is available for study.

Telegram & Insta: NCLEX_RN_Edu

F. Cryosurgery
1. Cryosurgery involves freezing of the tissues, using a probe, with subsequent necrosis and sloughing.
2. No anesthesia is required, although cramping may occur during the procedure.
3. A heavy watery discharge will occur for several weeks after the procedure; if heavy vaginal bleeding, fever, or foul-smelling drainage occurs, the PHCP needs to be notified.
4. Instruct the client to avoid intercourse and the use of tampons while the discharge is present.

G. Conization
1. A cone-shaped area of the cervix is removed.
2. Conization allows the client to retain reproductive capacity.
3. Long-term follow-up care is needed, because new lesions can develop.
4. The risks of the procedure include hemorrhage, uterine perforation, incompetent cervix, cervical stenosis, and preterm labor in future pregnancies.
5. For those who may wish to become pregnant in the future a radical trachelectomy may be done.

H. Hysterectomy
1. Description
   - **a.** Hysterectomy is performed for microinvasive cancer if childbearing is not desired.
   - **b.** A vaginal approach is most commonly used.
   - **c.** A radical hysterectomy and bilateral lymph node dissection may be performed for cancer that has spread beyond the cervix but not to the pelvic wall.
2. Postoperative interventions
   - **a.** Monitor vital signs.
   - **b.** Assist with coughing and deep-breathing exercises, and teach the use of incentive spirometry.
   - **c.** Assist with range-of-motion exercises, and provide early ambulation.
   - **d.** Apply antiembolism stockings or sequential compression devices as prescribed.
   - **e.** Monitor intake and output, urinary catheter drainage, and hydration status.
   - **f.** Monitor bowel sounds.
   - **g.** Assess incision site for signs of infection, such as foul-smelling or increased vaginal drainage. Assess for fever.
   - **h.** Administer pain medication as prescribed.
   - **i.** Instruct the client to limit stair climbing for 1 month as prescribed and to avoid tub baths and sitting for long periods.
   - **j.** Avoid strenuous activity or lifting anything weighing more than 20 pounds (9 kg).
   - **k.** Avoid driving for the time period specified by the surgeon.
   - **l.** Instruct the client to consume foods that promote tissue healing.
   - **m.** Instruct the client to avoid sexual intercourse for 3 to 6 weeks as prescribed.
   - **n.** Instruct the client in the signs associated with complications.

BOX 45.11 Types of Pelvic Exenteration

Anterior
- Removal of the uterus, ovaries, fallopian tubes, vagina, bladder, urethra, and pelvic lymph nodes

Posterior
- Removal of the uterus, ovaries, fallopian tubes, descending colon, rectum, and anal canal

Total
- Combination of anterior and posterior

Monitor vaginal bleeding after hysterectomy. More than one saturated pad per hour may indicate excessive bleeding.

I. Pelvic exenteration (Box 45.11)
1. Description
   - **a.** Pelvic exenteration, the removal of all pelvic contents, including bowel, vagina, and bladder, is a radical surgical procedure performed for recurrent cancer if no evidence of tumor outside the pelvis and no lymph node involvement exist.
   - **b.** When the bladder is removed, an ileal conduit is created and located on the right side of the abdomen to divert urine.
   - **c.** A colostomy may need to be created on the left side of the abdomen for the passage of feces.
2. Postoperative interventions
   - **a.** Similar to postoperative interventions after hysterectomy
   - **b.** Monitor for signs of altered respiratory status.
   - **c.** Monitor incision site for infection.
   - **d.** Monitor intake and output and for signs of dehydration.
   - **e.** Monitor for hemorrhage, shock, and deep vein thrombosis.
   - **f.** Apply antiembolism stockings or sequential compression devices as prescribed.
   - **g.** Administer prophylactic heparin as prescribed.
   - **h.** Administer perineal irrigations and sitz baths as prescribed.
   - **i.** Instruct the client to avoid strenuous activity for 6 months.

Telegram & Insta: NCLEX_RN_Edu

j. Instruct the client that the perineal opening, if present, may drain for several months.
k. Instruct the client in the care of the ileal conduit and colostomy, if created.
l. Provide sexual counseling, because vaginal intercourse is not possible after anterior and total pelvic exenteration.

XIV. Ovarian Cancer

A. Description
1. Ovarian cancer grows rapidly, spreads fast, and is often bilateral.
2. Metastasis occurs by direct spread to the organs in the pelvis, by distal spread through lymphatic drainage, or by peritoneal seeding.
3. In its early stages, ovarian cancer is often asymptomatic; because most are diagnosed in advanced stages, ovarian cancer has a higher mortality rate than any other cancer of the reproductive system, particularly among those who are white and between 55 and 65 years of age of North American or European descent.
4. An exploratory laparotomy is performed to diagnose and stage the tumor.
5. A transvaginal ultrasound may also be done for screening purposes but will not provide a definitive diagnosis.

B. Assessment
1. Abdominal discomfort or swelling
2. Urinary frequency
3. Weight loss
4. Gastrointestinal disturbances
5. Dysfunctional vaginal bleeding
6. Abdominal mass
7. Elevated tumor marker (i.e., CA-125)

C. Interventions
1. External radiation may be used if the tumor has invaded other organs; intraperitoneal radioisotopes may be instilled for stage I disease.
2. Chemotherapy is used postoperatively for most stages of ovarian cancer.
3. Intraperitoneal chemotherapy involves the instillation of chemotherapy into the abdominal cavity.
4. Total abdominal hysterectomy and bilateral salpingo-oophorectomy with tumor debulking may be necessary.

XV. Endometrial (Uterine) Cancer

A. Description
1. Endometrial cancer is a slow-growing tumor arising from the endometrial mucosa of the uterus, associated with the menopausal years.
2. Metastasis occurs through the lymphatic system to the ovaries and pelvis; via the blood to the lungs, liver, and bone; or intra-abdominally to the peritoneal cavity.

B. Risk factors
1. Use of estrogen replacement therapy (ERT) or birth control pills
2. Use of intrauterine device
3. Nulliparity
4. Polycystic ovary disease or endometrial hyperplasia
5. Increased age
6. Early menarche and late menopause
7. Family history of uterine cancer or hereditary nonpolyposis colorectal cancer
8. History of breast or ovarian cancer
9. Obesity
10. Hypertension
11. Diabetes mellitus

C. Assessment
1. Abnormal bleeding, especially in postmenopausal individuals
2. Vaginal discharge
3. Low back, pelvic, or abdominal pain (pain occurs late in the disease process)
4. Enlarged uterus (in advanced stages)

D. Nonsurgical interventions
1. External or internal radiation is used alone or in combination with surgery, depending on the stage of cancer.
2. Chemotherapy is used to treat advanced or recurrent disease.
3. Progesterone therapy with medication may be prescribed for estrogen-dependent tumors.
4. Antiestrogen medication may also be prescribed.

E. Surgical interventions: Total abdominal hysterectomy and bilateral salpingo-oophorectomy

XVI. Breast Cancer

A. Description
1. Breast cancer is classified as invasive when it penetrates the tissue surrounding the mammary duct and grows in an irregular pattern.
2. Metastasis occurs via lymph nodes.
3. Common sites of metastasis are the bone and lungs; metastasis may also occur to the brain and liver.
4. Diagnosis is made by breast biopsy through a needle aspiration or by surgical removal of the tumor with microscopic examination for malignant cells.

B. Risk factors
1. Age greater than 65 years
2. Family history of breast cancer due to genetic predisposition
3. Early menarche and late menopause
4. Previous cancer of the breast, uterus, or ovaries
5. Nulliparity, late first birth
6. Atypical hyperplasia of the breast
7. Oral contraceptive use

Telegram & Insta: NCLEX_RN_Edu

8. Recent hormone replacement therapy (HRT)
9. Obesity
10. High-dose radiation exposure to chest

C. Assessment

1. Mass felt during BSE (usually felt in the upper outer quadrant, beneath the nipple, or in axilla)
2. Presence of the lesion on mammography
3. A fixed, irregular nonencapsulated mass; typically painless except in the late stages
4. Asymmetry
5. Bloody or clear nipple discharge
6. Nipple retraction or elevation
7. Skin dimpling, retraction, or ulceration
8. Skin edema or peau d'orange skin
9. Axillary lymphadenopathy
10. Lymphedema of the affected arm
11. Symptoms of bone or lung metastasis in late stage

D. Early detection: Regular BSE

1. Performing BSE
   a. Perform regularly 7 to 10 days after menses.
   b. Postmenopausal clients or clients who have had a hysterectomy should perform BSE regularly as well.
2. Client instructions (Fig. 45.2)

E. Nonsurgical interventions

1. Chemotherapy
2. Radiation therapy
3. Hormonal manipulation via the use of medication in postmenopausal individuals or other medications for estrogen receptor–positive tumors
4. Monoclonal antibodies such as trastuzumab for human epidermal growth factor receptor 2–positive (HER-2 +) breast cancer

F. Surgical interventions: Surgical breast procedures, with possible breast reconstruction (Box 45.12)

G. Postoperative interventions

1. Monitor vital signs.
2. Position the client in a **semi-Fowler's position**; turn from the back to the unaffected side, with the affected arm elevated above the level of the heart to promote drainage and prevent lymphedema.
3. Encourage coughing and deep breathing and the use of incentive spirometry.
4. If a drain (usually a Jackson-Pratt) is in place, maintain suction and record the amount of drainage and drainage characteristics; teach the client about home management of the drain (Fig. 45.3).
5. Assess operative site for infection, swelling, or the presence of fluid collection under the skin flaps or in the arm.
6. Monitor incision site for restriction of dressing, impaired sensation, or color changes of the skin.

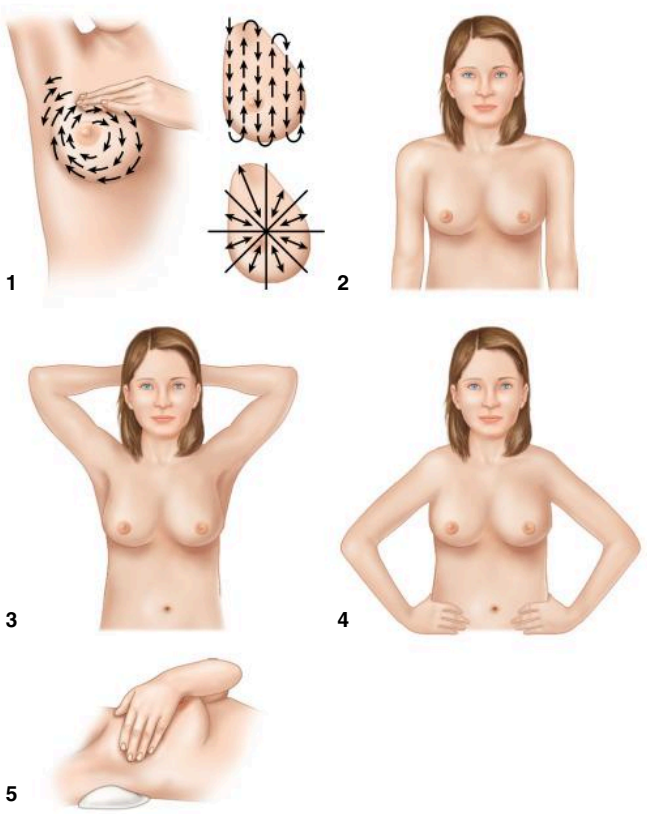

FIG. 45.2 Breast self-examination and client instructions. 1, While in the shower or bath, when the skin is slippery with soap and water, examine your breasts. Use the pads of your second, third, and fourth fingers to press every part of the breast firmly. Use your right hand to examine your left breast, and use your left hand to examine your right breast. Using the pads of the fingers on your left hand, examine the entire right breast using small circular motions in a spiral or up-and-down motion so that the entire breast area is examined. Repeat the procedure using your right hand to examine your left breast. Repeat the pattern of palpation under the arm. Check for any lump, hard knot, or thickening of the tissue. 2, Look at your breasts in a mirror. Stand with your arms at your side. 3, Raise your arms overhead and check for any changes in the shape of your breasts, dimpling of the skin, or any changes in the nipple. 4, Next, place your hands on your hips and press down firmly, tightening the pectoral muscles. Observe for asymmetry or changes, keeping in mind that your breasts probably do not match exactly. 5, While lying down, feel your breasts as described in step 1. When examining your right breast, place a folded towel under your right shoulder and put your right hand behind your head. Repeat the procedure while examining your left breast. Mark your calendar that you have completed your breast self-examination; note any changes or unique characteristics you want to check with your primary health care provider.

7. If breast reconstruction was performed, the client will return from surgery usually with a surgical brassiere and a prosthesis in place.
8. Provide the use of a pressure sleeve as prescribed if edema is severe.
9. Maintain fluid and electrolyte balance; administer diuretics and provide a low-salt diet as prescribed for severe lymphedema.
10. Consult with the PHCP and physical therapist regarding the appropriate exercise program, and assist the client with prescribed exercise.
11. Instruct the client about home care measures (Box 45.13).

Telegram & Insta: NCLEX_RN_Edu

BOX 45.12 Surgical Breast Procedures

Lumpectomy
- Tumor is excised and removed; affected breast tissue may be removed.
- Lymph node dissection may also be performed.

Simple Mastectomy
- Breast tissue and the nipple are removed.
- Lymph nodes are usually left intact.

Modified Radical Mastectomy
- Breast tissue, nipple, and lymph nodes are removed.
- Chest wall muscles are left intact if possible.

⚠ No IVs, no injections, no blood pressure measurements, and no venipunctures should be done in the arm on the side of the mastectomy. The arm on the side of the mastectomy is protected, and any intervention that could traumatize the affected arm is avoided because of the risk for lymphedema on this side.

XVII. Esophageal Cancer

A. Description
1. Esophageal cancer is a malignancy found in the esophageal mucosa, formed by squamous cell carcinoma (SCC) or adenocarcinoma.
2. Few observable signs are noticed in the early stages, and it usually has spread by the time the cancer causes symptoms.
3. The cause is unknown, but major risk factors include cigarette smoking, alcohol consumption, chronic reflux, Barrett's esophagus, and vitamin deficiencies.
4. Complications include dysphagia, painful swallowing, loss of appetite, and malaise.
5. Barrett's esophagus is a risk factor and may lead to high-grade dysplasia (HGD) and adenocarcinoma. Porfimer sodium and photodynamic therapy (PDT) may be used to ablate HGD and reduce the incidence of esophageal adenocarcinoma.
6. The goal of treatment is to inhibit tumor growth and maintain nutrition.

B. Assessment
1. Dysphagia
2. Odynophagia
3. Epigastric pain or sternal pain

C. Interventions
1. Monitor nutritional status, including daily weight, intake and output, and calories consumed.
2. Monitor the client closely while eating or drinking for signs of aspiration.

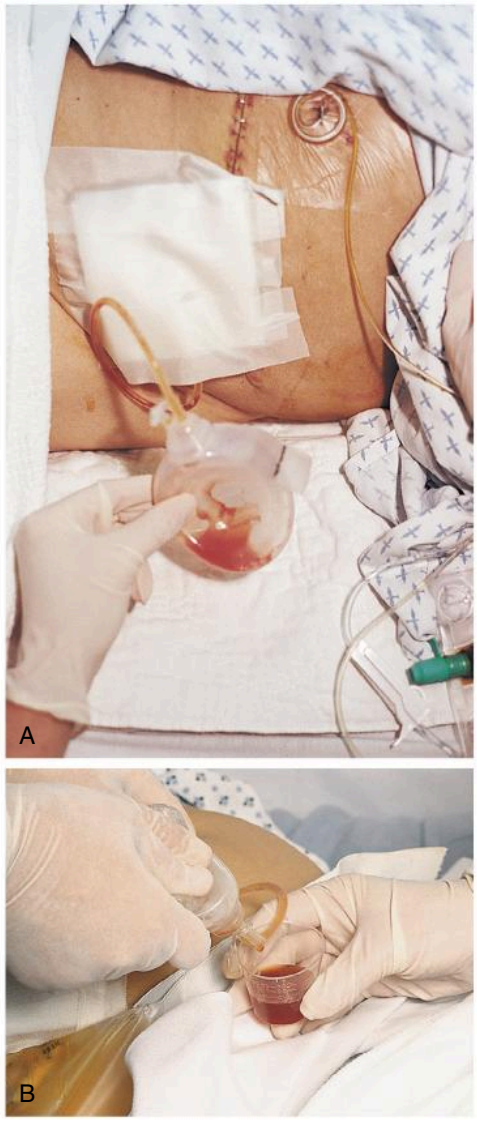

FIG. 45.3 Jackson-Pratt device. **A,** Drainage tubes and reservoir. **B,** Emptying drainage reservoir. (From Potter et al., 2013.)

3. Instruct the client about diet changes that make eating easier and less painful.
4. Prepare the client for chemotherapy and radiation as prescribed.
5. Prepare the client for surgical resection of the tumor as prescribed.

XVIII. Gastric Cancer

A. Description
1. Gastric cancer is a malignant growth of the mucosal cells in the inner lining of the stomach, with invasion to the muscle and beyond in advanced disease.
2. No single causative agent has been identified, but it is believed that *H. pylori* infection and a diet of smoked, highly salted, processed, or spiced foods have carcinogenic effects; other risk factors include smoking, alcohol and nitrate ingestion, and a history of gastric ulcers.

Telegram & Insta: NCLEX_RN_Edu

BOX 45.13 Client Instructions Following Mastectomy

- Avoid overuse of the arm during the first few months.
- To prevent lymphedema, keep the affected arm elevated; consultation with a lymphedema specialist may be prescribed.
- Provide incision care with an emollient as prescribed, to soften and prevent wound contracture.
- Encourage the use of support groups.
- Encourage the client to perform breast self-examination on the remaining breast and surgical site once healed.
- Return to usual activity level gradually, and avoid heavy lifting.
- Protect the affected hand and arm.
- Avoid strong sunlight on the affected arm.
- Do not let the affected arm hang dependent.
- Do not carry a pocketbook or anything heavy over the affected arm.
- Avoid trauma, cuts, bruises, or burns to the affected side.
- Avoid wearing constricting clothing or jewelry on the affected side.
- Wear gloves when gardening.
- Use thick oven mitts when cooking.
- Use a thimble when sewing.
- Apply hand cream several times daily.
- Use cream cuticle remover.
- Avoid participation in contact sports and other activities that can cause harm to the chest.
- Call the primary health care provider if signs of inflammation occur in the affected arm.
- Encourage discussion about feelings related to body image and self-esteem.
- Wear a MedicAlert bracelet stating which arm is at risk for lymphedema.

3. Complications include hemorrhage, obstruction, metastasis, and dumping syndrome.
4. The goal of treatment is to remove the tumor and provide a nutritional program.

B. Assessment

1. Early
   - **a.** Indigestion
   - **b.** Abdominal discomfort
   - **c.** Full feeling
   - **d.** Epigastric, back, or retrosternal pain
2. Late
   - **a.** Weakness and fatigue
   - **b.** Anorexia and weight loss
   - **c.** Nausea and vomiting
   - **d.** A sensation of pressure in the stomach
   - **e.** Dysphagia and obstructive symptoms
   - **f.** Iron-deficiency anemia
   - **g.** Ascites
   - **h.** Palpable epigastric mass
   - **i.** Enlarged lymph nodes

C. Interventions

1. Monitor vital signs.
2. Monitor hemoglobin and hematocrit, and administer blood transfusions as prescribed.

BOX 45.14 Surgical Interventions for Gastric Cancer

Subtotal Gastrectomy

Billroth I

- Also called gastroduodenostomy
- Partial gastrectomy, with remaining segment anastomosed to the duodenum

Billroth II

- Also called gastrojejunostomy
- Partial gastrectomy, with remaining segment anastomosed to the jejunum

Total Gastrectomy

- Also called esophagojejunostomy
- Removal of the stomach, with attachment of the esophagus to the jejunum or duodenum

3. Monitor weight.
4. Assess nutritional status; encourage small, bland, easily digestible meals with vitamin and mineral supplements.
5. Administer pain medication as prescribed.
6. Prepare the client for chemotherapy or radiation therapy as prescribed.
7. Prepare the client for surgical resection of the tumor as prescribed (Box 45.14).

D. Postoperative interventions

1. Monitor vital signs.
2. Place in **Fowler's position** for comfort.
3. Administer analgesics and antiemetics, as prescribed.
4. Monitor intake and output; administer fluids and electrolyte replacement by IV as prescribed; administer parenteral nutrition as indicated.
5. Maintain NPO (nothing by mouth) status as prescribed for 1 to 3 days until peristalsis returns; assess for bowel sounds.
6. Monitor nasogastric suction. Following gastrectomy, drainage from the nasogastric tube is normally bloody for 24 hours postoperatively, changes to brown-tinged, and is then yellow or clear.
7. Do not irrigate or remove the nasogastric tube (follow agency procedures); assist the PHCP with irrigation or removal.
8. Advance the diet from NPO to sips of clear water to six small bland meals a day, as prescribed.
9. Monitor for complications such as hemorrhage, dumping syndrome, diarrhea, **hypoglycemia**, and vitamin B_{12} deficiency.

XIX. Pancreatic Cancer

A. Description

1. Most pancreatic tumors are highly malignant, rapidly growing adenocarcinomas originating from the epithelium of the ductal system.

Telegram & Insta: NCLEX_RN_Edu

2. Pancreatic cancer is associated with increased age, a history of diabetes mellitus, alcohol use, history of previous pancreatitis, smoking, ingestion of a high-fat diet, and exposure to environmental chemicals.
3. Symptoms usually do not occur until the tumor is large; therefore, the prognosis is poor.
4. Endoscopic retrograde cholangiopancreatography for visualization of the pancreatic duct and biliary system and collection of tissue and secretions may be done.

B. Assessment
1. Nausea and vomiting
2. Ascites
3. Jaundice
4. Unexplained weight loss
5. Clay-colored stools; dark colored urine
6. Glucose intolerance
7. Abdominal pain

C. Interventions
1. Radiation
2. Chemotherapy
3. Whipple procedure, which involves a pancreaticoduodenectomy with removal of the distal third of the stomach, pancreaticojejunostomy, gastrojejunostomy, and choledochojejunostomy (Fig. 45.4)
4. Postoperative care measures and complications are similar to those for the care of a client with pancreatitis and the client following gastric surgery; monitor blood glucose levels for transient hyperglycemia or hypoglycemia resulting from surgical manipulation of the pancreas.

XX. Intestinal Tumors

A. Description
1. Intestinal tumors are malignant lesions that develop in the cells lining the bowel wall or develop as adenomatous polyps in the colon or rectum.
2. Tumor spread is by direct invasion and through the lymphatic and circulatory systems.
3. Complications include bowel perforation with peritonitis, abscess and fistula formation, hemorrhage, and complete intestinal obstruction.

B. Risk factors for colorectal cancer
1. Age older than 50 years
2. Familial polyposis, family history of colorectal cancer (first-degree relative presents a high risk)
3. Previous colorectal polyps, history of colorectal cancer
4. History of chronic inflammatory bowel disease
5. History of ovarian or breast, endometrial, and stomach cancers

C. Assessment
1. Blood in stool (most common manifestation) detected by fecal occult blood testing, sigmoidoscopy, and colonoscopy

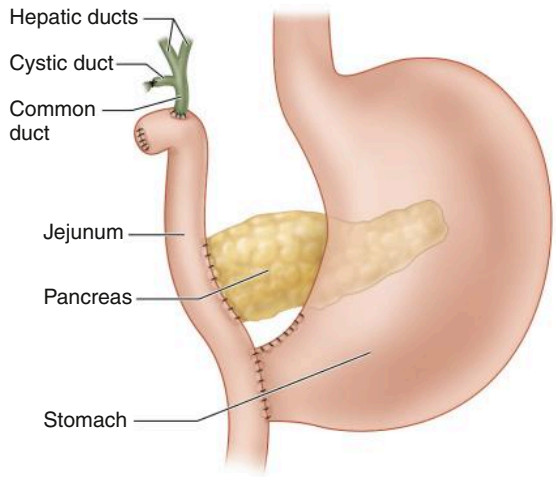

FIG. 45.4 Whipple procedure, or radical pancreaticoduodenectomy.

2. Anorexia, vomiting, and weight loss
3. Anemia
4. Abnormal stools
   a. Ascending colon tumor: Diarrhea
   b. Descending colon tumor: Constipation or some diarrhea, or flat, ribbon-like stool caused by a partial obstruction
   c. Rectal tumor: Alternating constipation and diarrhea
5. Guarding or abdominal distention, abdominal mass (late sign)
6. Cachexia (late sign)
7. Masses noted on barium enema, colonoscopy, CT scan, sigmoidoscopy

D. General interventions
1. Monitor for signs of complications, which include bowel perforation with peritonitis, abscess or fistula formation (fever associated with pain), hemorrhage (signs of shock), and complete intestinal obstruction.
2. Monitor for signs of bowel perforation, which include low blood pressure, rapid and weak pulse, distended abdomen, and elevated temperature.
3. Monitor for signs of intestinal obstruction, which include vomiting (may be fecal contents), pain, constipation, and abdominal distention; provide comfort measures.
4. Note that an early sign of intestinal obstruction is increased peristaltic activity, which produces an increase in bowel sounds; as the obstruction progresses, hypoactive bowel sounds may be heard.
5. Prepare for radiation preoperatively to facilitate surgical resection, and postoperatively to decrease the risk of recurrence or to reduce pain, hemorrhage, bowel obstruction, or metastasis.

E. Nonsurgical interventions
1. Preoperative radiation for local control and postoperative radiation for palliation may be prescribed.

Telegram & Insta: NCLEX_RN_Edu

2. Postoperative chemotherapy to control symptoms and the spread of disease

F. Surgical interventions: Bowel resection, local lymph node resection, and creation of a colostomy or ileostomy

G. Colostomy, ileostomy

1. Preoperative interventions
   a. Consult with the enterostomal therapist to assist in identifying optimal placement of the ostomy.
   b. Instruct the client in prescribed preoperative diet; bowel preparation (laxatives and enemas) may be prescribed per surgeon preference.
   c. Intestinal antiseptics and antibiotics may be prescribed to decrease the bacterial content of the colon and to reduce the risk of infection from the surgical procedure.

2. Postoperative: Colostomy
   a. If a pouch system is not in place, apply a petroleum jelly gauze over the stoma to keep it moist, and cover with a dry sterile dressing. Place a pouch system on the stoma as soon as possible.
   b. Monitor the pouch system for proper fit and signs of leakage; empty the pouch when one-third full.
   c. Monitor the stoma for size, unusual bleeding, color changes, or necrotic tissue.
   d. Note that the normal stoma color is red or pink, indicating high vascularity.
   e. Note that a pale pink stoma indicates low hemoglobin and hematocrit levels.
   f. Assess the functioning of the colostomy; usually functioning starts in 2 to 3 days.
   g. Expect that stool will be liquid postoperatively but will become more solid, depending on the area of the colostomy.
   h. Expect liquid stool from an ascending colon colostomy, loose to semiformed stool from a transverse colon colostomy, or close to normal stool from a descending colon colostomy.
   i. Fecal matter should not be allowed to remain on the skin.
   j. Administer analgesics and antibiotics as prescribed.
   k. Irrigate perineal wound if present and if prescribed, and monitor for signs of infection; provide comfort measures for perineal itching and pain.
   l. Instruct the client to avoid foods that cause excessive gas formation and odor; carbonated beverages should also be avoided.
   m. Instruct the client in stoma care and irrigations as prescribed.
   n. Instruct the client on when to resume normal activities, including work, travel, and sexual intercourse, as prescribed; provide psychosocial support.

3. Postoperative: Ileostomy
   a. Healthy stoma is red in color.
   b. Postoperative drainage will be dark green and progress to yellow as the client begins to eat.
   c. Stool is liquid.
   d. Risk for dehydration and electrolyte imbalance exists.

⚠ Monitor stoma color. A dark blue, purple, or black stoma indicates compromised circulation, requiring notification of the surgeon.

XXI. Lung Cancer

A. Description

1. Lung cancer is a malignant tumor of the bronchi and peripheral lung tissue.
2. The lungs are a common target for metastasis from other organs.
3. Bronchogenic cancer (tumors originate in the epithelium of the bronchus) spreads through direct extension and lymphatic dissemination.
4. Classified according to histological cell type; types include small cell lung cancer (SCLC) and non–small cell lung cancer (NSCLC); epidermal (squamous cell), adenocarcinoma, and large cell anaplastic carcinoma are classified as NSCLC because of their similar responses to treatment.
5. Diagnosis is made by a chest x-ray study, CT and PET scan, or magnetic resonance imaging (MRI), which would show a lesion or mass, and by bronchoscopy and sputum studies, which demonstrate a positive cytological study for cancer cells.

B. Causes

1. Cigarette smoking; also exposure to "passive" tobacco smoke
2. Exposure to environmental and occupational pollutants

C. Assessment

1. Cough
2. Wheezing, dyspnea
3. Hoarseness
4. Hemoptysis, blood-tinged or purulent sputum
5. Chest pain
6. Anorexia and weight loss
7. Weakness
8. Diminished or absent breath sounds, respiratory changes leading to hypoxia
9. Clubbing to finger nail beds

D. Interventions

1. Monitor vital signs, including pulse oximetry.
2. Monitor breathing patterns and breath sounds and for signs of respiratory impairment; monitor for hemoptysis.
3. Assess for tracheal deviation.
4. Administer analgesics as prescribed for pain management.
5. Place in a Fowler's position to help ease breathing.

Telegram & Insta: NCLEX_RN_Edu

6. Administer oxygen as prescribed and humidification to moisten and loosen secretions.
7. Assess for malignant pleural effusions.
8. Provide respiratory treatments as prescribed.
9. Teach client relaxation breathing techniques.
10. Administer bronchodilators and corticosteroids as prescribed to decrease bronchospasm, inflammation, and edema.
11. Provide a high-calorie, high-protein, high-vitamin diet.
12. Provide activity as tolerated, rest periods, and active and passive range-of-motion exercises.

E. Nonsurgical interventions
1. Radiation therapy may be prescribed for localized intrathoracic lung cancer and for palliation of hemoptysis, obstructions, dysphagia, superior vena cava syndrome, and pain.
2. Chemotherapy may be prescribed for treatment of nonresectable tumors or as adjuvant therapy.

F. Surgical interventions
1. Laser therapy: To relieve endobronchial obstruction
2. Thoracentesis, chest tube, drain placement or pleurodesis: To remove pleural fluid and relieve hypoxia, often indicated in recurrent malignant pleural effusions
3. Thoracotomy (opening into the thoracic cavity) with pneumonectomy: Surgical removal of one entire lung
4. Thoracotomy with lobectomy: Surgical removal of one lobe of the lung for tumors confined to a single lobe
5. Thoracotomy with segmental resection: Surgical removal of a lobe segment

G. Other therapies: Other therapies include such interventions as immunotherapy, targeted therapy, photodynamic therapy, airway stenting, and radiofrequency ablation, some of which may require surgical intervention.

H. Preoperative interventions
1. Explain the potential postoperative need for chest tubes.
2. Note that closed chest drainage usually is not used for a pneumonectomy, and the serous fluid that accumulates in the empty thoracic cavity eventually consolidates, preventing shifts of the mediastinum, heart, and remaining lung.

I. Postoperative interventions
1. Monitor vital signs, including pulse oximetry.
2. Assess cardiac and respiratory status; monitor lung sounds.
3. Maintain the chest tube drainage system, which drains air and blood that accumulates in the pleural space; monitor for excess bleeding. (See Chapter 70 for care of the client with a chest tube.)
4. Administer oxygen as prescribed.

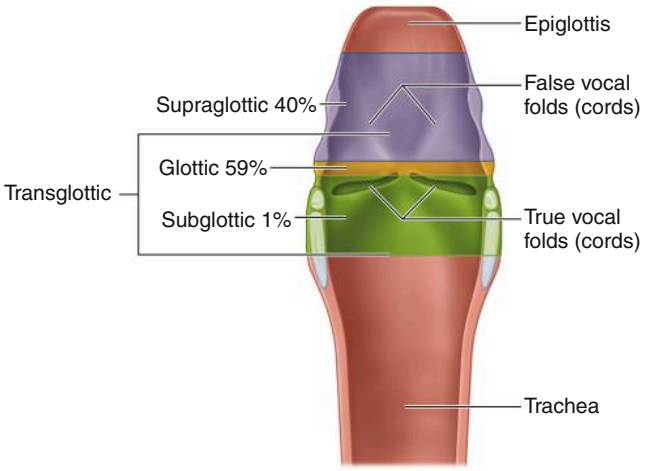

FIG. 45.5 Sites and incidence of primary laryngeal tumors.

5. Check the surgeon's prescriptions regarding client positioning; avoid complete lateral turning.
6. Provide activity as tolerated.
7. Encourage active range-of-motion exercises of the operative shoulder as prescribed.

The airway is the priority for a client with lung or laryngeal cancer.

XXII. Laryngeal Cancer

A. Description
1. Laryngeal cancer is a malignant tumor of the larynx (Fig. 45.5).
2. Laryngeal cancer presents as malignant ulcerations with underlying infiltration and is spread by local extension to adjacent structures in the throat and neck and by the lymphatic system.
3. Diagnosis is made by laryngoscopy and biopsy of tissues showing a positive cytological study for cancer cells.
4. Chest radiography, CT, and MRI are used for staging.

B. Risk factors
1. Cigarette smoking
2. Heavy alcohol use and the combined use of tobacco and alcohol
3. Exposure to environmental pollutants (e.g., asbestos, wood dust)
4. Exposure to radiation

C. Assessment
1. Persistent hoarseness or sore throat and ear pain
2. Painless neck mass
3. Feeling of a lump in the throat
4. Burning sensation in the throat
5. Dysphagia
6. Change in voice quality
7. Dyspnea
8. Weakness and weight loss
9. Hemoptysis
10. Foul breath odor

Telegram & Insta: NCLEX_RN_Edu

D. Interventions

1. Place in Fowler's position to promote optimal air exchange.
2. Monitor respiratory status.
3. Monitor for signs of aspiration of food and fluid.
4. Administer oxygen as prescribed.
5. Provide respiratory treatments as prescribed.
6. Provide activity as tolerated.
7. Provide a high-calorie and high-protein diet.
8. Provide nutritional support via parenteral nutrition, nasogastric tube feedings, or gastrostomy or jejunostomy tube, as prescribed.
9. Administer analgesics as prescribed for pain.
10. Encourage clients to stop smoking and drinking alcohol to increase effectiveness of treatments.

E. Nonsurgical interventions

1. Radiation therapy in specified situations
2. Chemotherapy, which may be given in combination with radiation and surgery

F. Surgical interventions

1. The goal is to remove the cancer while preserving as much normal function as possible.
2. Surgical intervention depends on the tumor size, location, and amount of tissue to be resected.
3. Types of resection include cordal stripping, cordectomy, partial laryngectomy, and total laryngectomy.
4. A tracheostomy is performed with a total laryngectomy; this airway opening is permanent and is referred to as a *laryngectomy stoma*.

G. Preoperative interventions

1. Discuss self-care of the airway, alternative methods of communication, suctioning, pain control methods, the critical care environment, and nutritional support.
2. Encourage the client to express feelings about changes in body image and loss of voice.
3. Describe the rehabilitation program and information about the tracheostomy and suctioning.

H. Postoperative interventions

1. Monitor vital signs, including pulse oximetry
2. Monitor respiratory status; monitor airway patency, and provide frequent suctioning to remove bloody secretions.
3. Place the client in a high-Fowler's position.
4. Maintain mechanical ventilator support or a tracheostomy collar with humidification, as prescribed.
5. Maintain surgical drains in the neck area if present.
6. Observe for hemorrhage and edema in the neck.
7. Monitor IV fluids or parenteral nutrition until nutrition is administered via a nasogastric, gastrostomy, or jejunostomy tube.
8. Teach the client gastrostomy or jejunostomy tube care; to wear protective clothing made of soft cotton; and to wash this area gently daily with a mild soap.
9. Provide oral hygiene.
10. Assess gag and cough reflexes and the ability to swallow.
11. Increase activity as tolerated.
12. Assess the color, amount, and consistency of sputum.
13. Provide stoma and laryngectomy care (Box 45.15).
14. Provide consultation with speech and language pathologist as prescribed.
15. Reinforce method of communication established preoperatively.
16. Prepare the client for rehabilitation and speech therapy (Box 45.16).

BOX 45.15 Stoma Care Following Laryngectomy

- Protect the neck from injury.
- Instruct the client in how to clean the incision and provide stoma care.
- Instruct the client to wear a stoma guard to shield the stoma.
- Instruct the client to use a shower shield over the stoma when bathing to prevent water from entering the airway.
- Demonstrate ways to prevent debris from entering the stoma.
- Advise the client to wear loose-fitting, high-collared clothing to cover the stoma.
- Avoid swimming, showering, and using aerosol sprays.
- Teach the client clean suctioning technique.
- Advise the client to increase humidity in the home.
- Increase fluid intake to 3000 mL/day as prescribed.
- Avoid exposure to persons with infections.
- Alternate rest periods with activity.
- Instruct the client in range-of-motion exercises for the arms, shoulders, and neck as prescribed.
- Advise the client to wear a MedicAlert bracelet.

XXIII. Prostate Cancer

A. Description

1. Prostate cancer, a slow-growing malignancy of the prostate gland, is a common cancer in Americans; most prostate tumors are adenocarcinomas arising from androgen-dependent epithelial cells.
2. The risk increases with each decade after the age of 50 years.
3. Prostate cancer can spread via direct invasion of surrounding tissues or by metastasis through the bloodstream and lymphatics.
4. Bone metastasis is a concern, as is spread to the lungs, liver, and kidneys.
5. The cause of prostate cancer is unclear, but advancing age, heavy metal exposure, smoking, and history of sexually transmitted infection are contributing factors.

Telegram & Insta: NCLEX_RN_Edu

BOX 45.16 Speech Rehabilitation Following Laryngectomy

Esophageal Speech

- The client produces esophageal speech by "burping" the air swallowed.
- The voice produced is monotone, cannot be raised or lowered, and carries no pitch.
- The client must have adequate hearing because the mouth is used to shape words as they are heard.

Mechanical Devices

- One device, the electrolarynx, is placed against the side of the neck; the air inside the neck and pharynx is vibrated, and the client articulates.
- Another device consists of a plastic tube that is placed inside the client's mouth and vibrates on articulation.

Tracheoesophageal Fistula

- A fistula is created surgically between the trachea and the esophagus, with eventual placement of a prosthesis to produce speech.
- The prosthesis provides the client with a means to divert air from the trachea into the esophagus, and out of the mouth.
- Lip and tongue movement produce the speech.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Saunders. p.528.

6. The client should discuss appropriate screening procedures with the PHCP.

B. Assessment
1. Asymptomatic in early stages
2. Hard, pea-sized nodule or irregularities palpated on rectal examination
3. Gross, painless hematuria
4. Late symptoms such as weight loss, urinary obstruction, and bone pain radiating from the lumbosacral area down the leg; frequent bladder infections are common.
5. The prostate-specific antigen level is elevated in various noncancerous conditions; therefore, it should not be used as a screening test without a digital rectal examination. It is routinely used to monitor response to therapy.
6. Diagnosis is made through biopsy of the prostate gland.

C. Nonsurgical interventions
1. Prepare the client for hormone manipulation therapy (androgen suppression therapy) as prescribed or active surveillance with prostate-specific antigen (PSA) and digital rectal examination (DRE).
2. Luteinizing hormone may be prescribed to slow the rate of growth of the tumor.
3. Medication adverse effects include reduced libido, hot flashes, breast tenderness, osteoporosis, loss of muscle mass, and weight gain. The client should be informed of these effects.

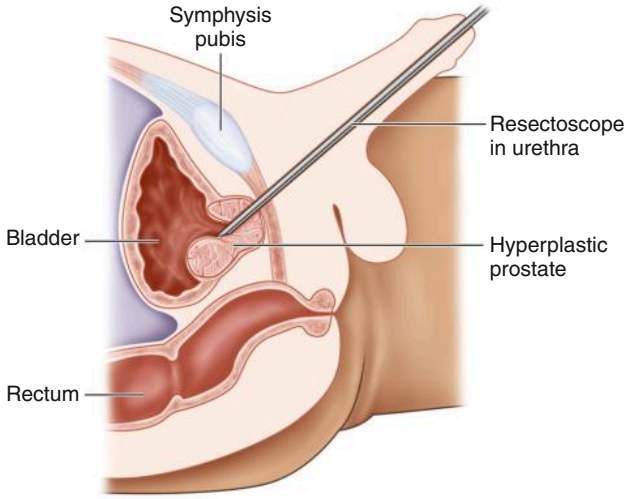

FIG. 45.6 Transurethral resection of the prostate.

4. Pain medication, radiation therapy, corticosteroids, and bisphosphonates may be prescribed for palliation of advanced prostate cancer.
5. Prepare the client for external beam radiation or brachytherapy, which may be prescribed alone or with surgery, preoperatively or postoperatively, to reduce the lesion and limit metastasis.
6. Prepare the client for the administration of chemotherapy if hormone manipulation therapy is ineffective.

D. Surgical interventions
1. Prepare the client for orchiectomy (palliative), if prescribed, which will limit the production of testosterone.
2. Prepare the client for prostatectomy, if prescribed.
3. The radical prostatectomy can be performed via a retropubic, perineal, or suprapubic approach.
4. Cryosurgical ablation is a minimally invasive procedure that may be an alternative to radical prostatectomy; liquid nitrogen freezes the gland, and the dead cells are absorbed by the body.

E. Transurethral resection of the prostate (TURP) may be performed for palliation in prostate cancer clients (Fig. 45.6).
1. The procedure involves insertion of a scope into the urethra to excise prostatic tissue.
2. Monitor for hemorrhage; bleeding is common following TURP.
3. Postoperative continuous bladder irrigation (CBI) may be prescribed, which prevents catheter obstruction from clots.
4. Monitor output and for obstruction; irrigate per prescription, and notify the surgeon immediately if obstruction does not resolve.
5. Assess for signs of transurethral resection syndrome, which includes signs of cerebral edema and increased intracranial pressure, such as increased

Telegram & Insta: NCLEX_RN_Edu

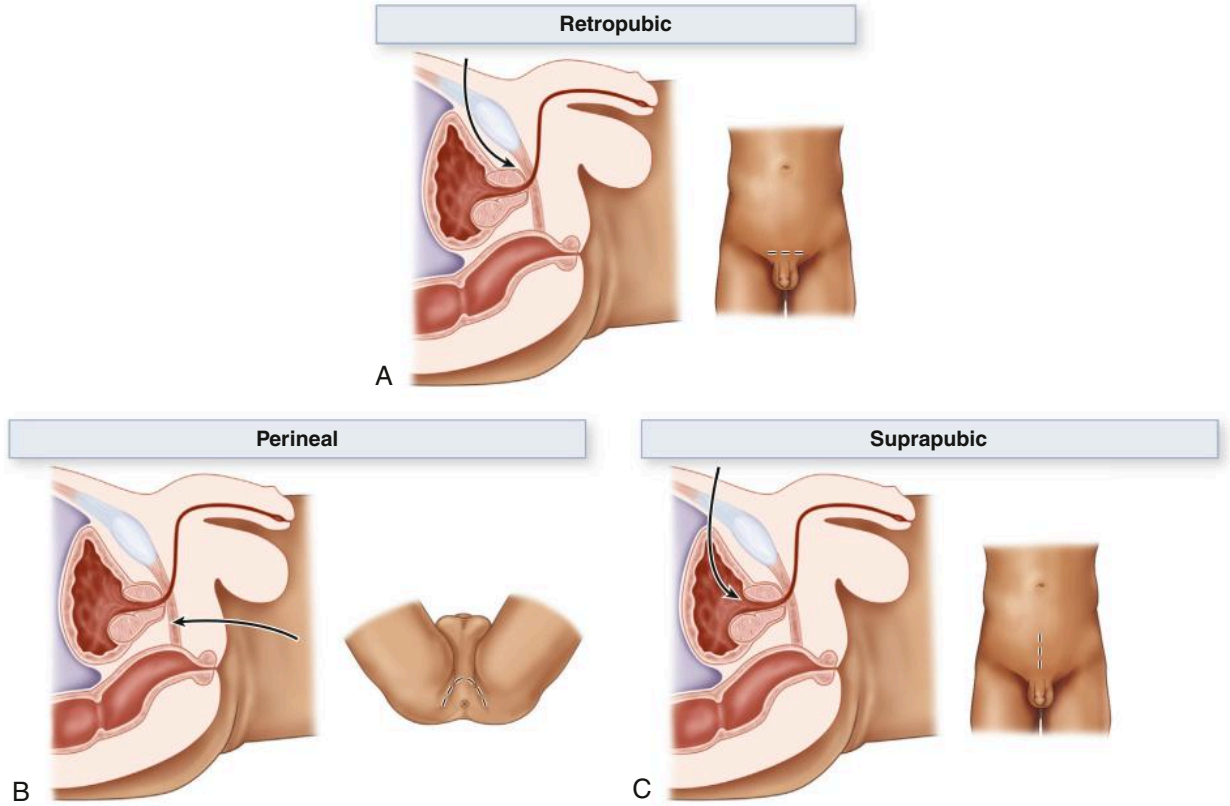

FIG. 45.7 Surgical approaches to prostatectomy **A,** Retropubic approach involves a low abdominal incision. **B,** Perineal approach involves an incision between the scrotum and anus. **C,** Suprapubic approach involves a midline abdominal incision.

blood pressure, bradycardia, confusion, disorientation, muscle twitching, visual disturbances, and nausea and vomiting.

6. Antispasmodics may be prescribed for bladder spasm.
7. Instruct the client to monitor and report dribbling or incontinence postoperatively, and teach perineal exercises.
8. Sterility is possible following the surgical procedure.

F. Suprapubic prostatectomy (Fig. 45.7)

1. Suprapubic prostatectomy is removal of the prostate gland by an abdominal incision with a bladder incision.
2. The client will have an abdominal dressing that may drain copious amounts of urine, and the abdominal dressing will need to be changed frequently.
3. Severe hemorrhage is possible, and monitoring for blood loss is an important nursing intervention.
4. Antispasmodics may be prescribed for bladder spasms.
5. CBI is prescribed and carried out to maintain pink-colored urine.
6. Monitor output and for obstruction; irrigate per prescription, and notify the surgeon immediately if obstruction does not resolve.
7. Sterility occurs with this procedure.

G. Retropubic prostatectomy (see Fig. 45.7)

1. Retropubic prostatectomy is removal of the prostate gland by a low abdominal incision without opening the bladder.
2. Less bleeding occurs with this procedure compared with the suprapubic procedure, and the client experiences fewer bladder spasms.
3. Abdominal drainage is minimal.
4. CBI may be used.
5. Sterility occurs with this procedure.

H. Perineal prostatectomy (see Fig. 45.7)

1. The prostate gland is removed through an incision made between the scrotum and anus.
2. Minimal bleeding occurs with this procedure.
3. The client needs to be monitored closely for infection, because the risk of infection is increased with this type of prostatectomy.
4. Urinary incontinence is common.
5. The procedure causes sterility.
6. Teach the client how to perform perineal exercises.

I. Postoperative interventions

1. Monitor vital signs.
2. Monitor urinary output and urine for hemorrhage or clots.
3. Increase fluids to 2400 to 3000 mL/day, unless contraindicated.

Telegram & Insta: NCLEX_RN_Edu

4. Monitor for arterial bleeding as evidenced by bright red urine with numerous clots; if it occurs, increase CBI and notify the surgeon immediately.
5. Monitor for venous bleeding as evidenced by burgundy-colored urine output; if it occurs, inform the surgeon, who may apply traction on the catheter.
6. Monitor output and for obstruction; irrigate per prescription, and notify the surgeon immediately if obstruction does not resolve.
7. Monitor hemoglobin and hematocrit levels.
8. Expect red to light pink urine for 24 hours, turning to amber in 3 days.
9. Ambulate the client as early as possible and as soon as urine begins to clear in color.
10. Inform the client that a continuous feeling of an urge to void is normal.
11. Instruct the client to avoid attempts to void around the catheter, because this will cause bladder spasms.
12. Administer antibiotics, analgesics, stool softeners, and antispasmodics as prescribed.
13. Monitor the three-way urinary catheter, which usually has a 30- to 45-mL retention balloon.
14. Maintain CBI with sterile bladder irrigation solution as prescribed to keep the catheter free of obstruction and keep the urine pink in color (Box 45.17).

⚠ Following TURP, monitor for transurethral resection syndrome or severe hyponatremia (water intoxication) caused by the excessive absorption of bladder irrigation during surgery. Signs include altered mental status, bradycardia, increased blood pressure, and confusion.

J. Postoperative interventions: Suprapubic prostatectomy

1. Monitor suprapubic and urinary catheter drainage.
2. Monitor CBI if prescribed.
3. Note that the urinary catheter will be removed 2 to 4 days postoperatively if the client has a suprapubic catheter.
4. If prescribed, clamp the suprapubic catheter after the urinary catheter is removed, and instruct the client to attempt to void; after the client has voided, assess the residual urine in the bladder by unclamping the suprapubic catheter and measuring the output.
5. Prepare for removal of the suprapubic catheter when the client consistently empties the bladder and residual urine is 75 mL or less or as prescribed.
6. Monitor the suprapubic incision dressing, which may become saturated with urine, until the incision heals; dressing may need to be changed frequently.

BOX 45.17 Continuous Bladder Irrigation (CBI)

Description

- A three-way (lumen) irrigation is used to decrease bleeding and to keep the bladder free from clots—one lumen is for inflating the balloon (30 mL); one lumen is for instillation (inflow); one lumen is for outflow.

Interventions

- Maintain traction on the catheter, if applied and prescribed, to prevent bleeding by pulling the catheter taut and taping it to the abdomen or thigh.
- Instruct the client to keep the leg straight if traction is applied to the catheter and it is taped to the thigh.
- Catheter traction is not released without the surgeon's prescription; it usually is released after any bright red drainage has diminished.
- Use only sterile bladder irrigation solution or prescribed solution to prevent water intoxication.
- Run the solution at a rate, as prescribed, to keep the urine pink. Run the solution rapidly if bright red drainage or clots are present; monitor output closely. Run the solution at about 40 drops (gtt)/minute when the bright red drainage clears.
- If the urinary catheter becomes obstructed, turn off the CBI and irrigate the catheter with 30 to 50 mL of normal saline, if prescribed; notify the surgeon if obstruction does not resolve.
- Discontinue CBI and the urinary catheter as prescribed, usually 24 to 48 hours after surgery.
- Monitor for continence and urinary retention when the catheter is removed. Inform the client that some burning, frequency, and dribbling may occur after catheter removal.
- Inform the client that they should be voiding 150 to 200 mL of clear yellow urine every 3 to 4 hours by 3 days after surgery.
- Inform the client that they may pass small clots and tissue debris for several days.
- Teach the client to avoid heavy lifting, stressful exercise, driving, the Valsalva maneuver, and sexual intercourse for 2 to 6 weeks to prevent strain, and to call the surgeon if bleeding occurs or if there is a decrease in urinary stream.
- Instruct the client to drink 2400 to 3000 mL of fluid each day, preferably before 8 p.m. to avoid nocturia.
- Instruct the client to avoid alcohol, caffeinated beverages, and spicy foods and overstimulation of the bladder.
- Instruct the client that if the urine becomes bloody, to rest and increase fluid intake and, if the bleeding does not subside, to notify the surgeon.

K. Postoperative interventions: Retropubic prostatectomy

1. Note that because the bladder is not entered, there is no urinary drainage on the abdominal dressing; if urinary or purulent drainage is noted on the dressing, notify the surgeon.
2. Monitor for fever and increased pain, which may indicate an infection.

L. Postoperative interventions: Perineal prostatectomy

1. Note that the client will have an incision, which may or may not have a drain.

Telegram & Insta: NCLEX_RN_Edu

2. Avoid the use of rectal thermometers, rectal tubes, and enemas, because they may cause trauma and bleeding.

XXIV. Bladder Cancer

A. Description
1. Bladder cancer is a papillomatous growth in the bladder urothelium that undergoes malignant changes and that may infiltrate the bladder wall.
2. Predisposing factors include cigarette smoking, exposure to industrial chemicals, and exposure to radiation.
3. Common sites of metastasis include the liver, bones, and lungs.
4. As the tumor progresses, it can extend into the rectum, vagina, other pelvic soft tissues, and retroperitoneal structures.

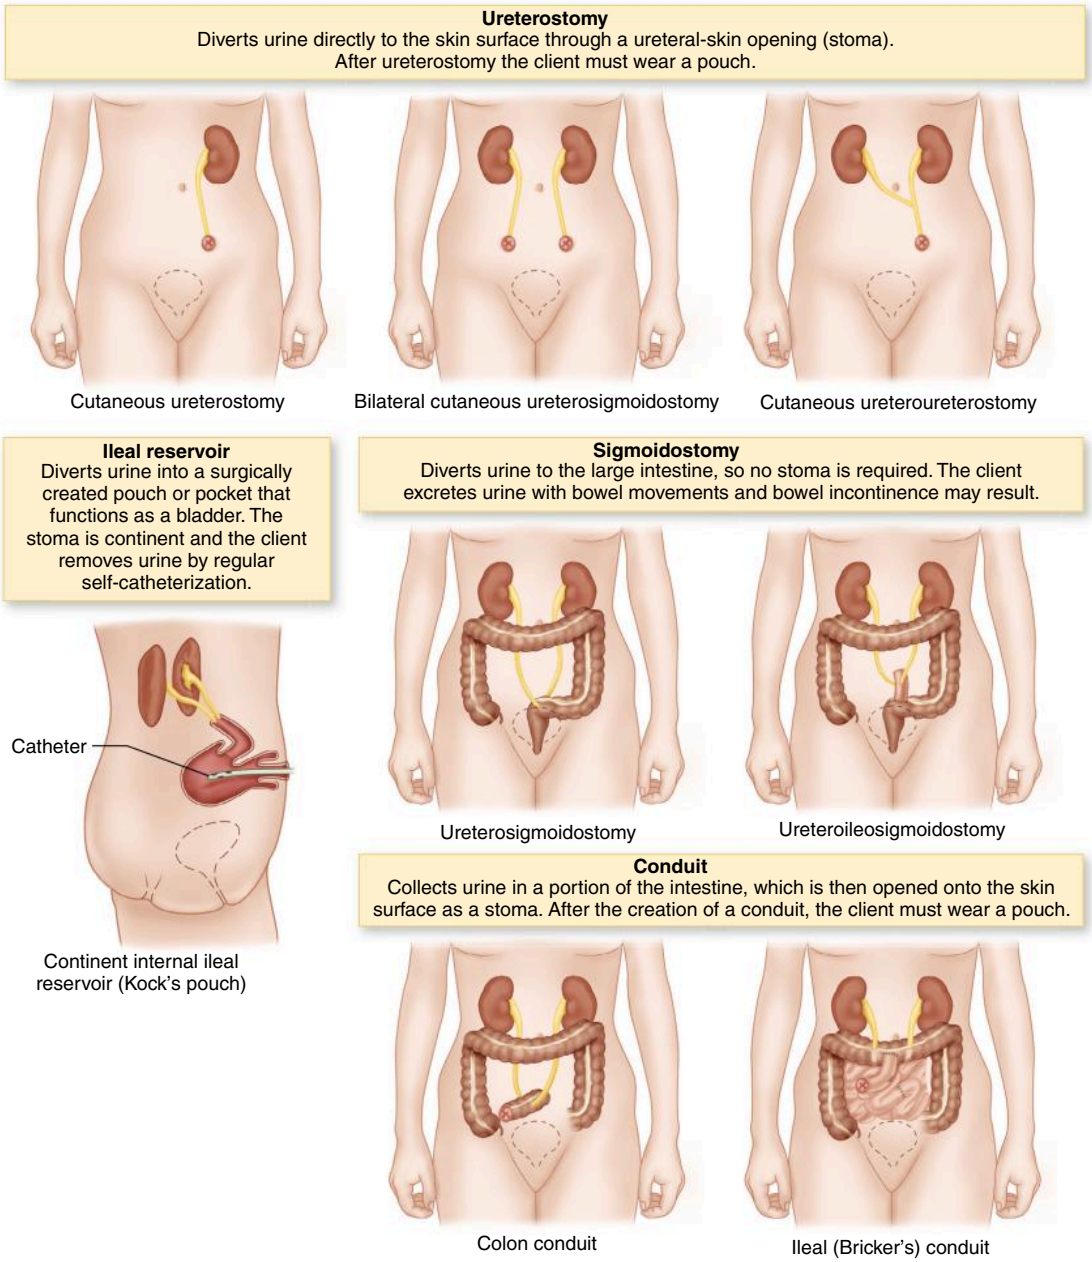
B. Assessment
1. Gross or microscopic, painless hematuria (most common sign)
2. Frequency, urgency, dysuria
3. Clot-induced obstruction
4. Bladder wash specimens and biopsy confirm diagnosis.

C. Radiation
1. Radiation therapy is indicated for advanced disease that cannot be eradicated by surgery; palliative radiation may be used to relieve pain and bowel obstruction and control potential hemorrhage and leg edema caused by venous or lymphatic obstruction.
2. Intracavitary radiation may be prescribed, which protects adjacent tissue.
3. External beam radiation combined with chemotherapy or surgery may be prescribed to improve survival.
4. Complications of radiation
   a. Abacterial cystitis
   b. Proctitis
   c. Fistula formation
   d. Ileitis or colitis
   e. Bladder ulceration and hemorrhage

D. Chemotherapy
1. Intravesical instillation
   a. An alkylating chemotherapeutic agent is instilled into the bladder.
   b. This method provides a concentrated topical treatment with little systemic absorption.
   c. The medication is injected into a urethral catheter and retained for 2 hours.
   d. Following instillation, the client's position is rotated every 15 to 30 minutes, starting in the supine position, to avoid lying on a full bladder.
   e. After 2 hours, the client voids in a sitting position and is instructed to increase fluids to flush the bladder.
   f. Treat the urine as a biohazard, and send to the radioisotope laboratory for monitoring.
   g. For 6 hours following intravesical chemotherapy, disinfect the toilet with household bleach after the client has voided.
2. Systemic chemotherapy: Used to treat inoperable tumors or distant metastasis
3. Complications of chemotherapy
   a. Bladder irritation
   b. Hemorrhagic cystitis

E. Surgical interventions
1. Transurethral resection of bladder tumor
   a. Local resection and fulguration (destruction of tissue by electrical current through electrodes placed in direct contact with the tissue)
   b. Performed for early tumors for cure or for inoperable tumors for palliation
2. Partial cystectomy
   a. Partial cystectomy is the removal of up to half the bladder.
   b. The procedure is done for early-stage tumors and for clients who cannot tolerate a radical cystectomy.
   c. During the initial postoperative period, bladder capacity is reduced greatly to about 60 mL; however, as the bladder tissue expands, the capacity increases to 200 to 400 mL.
   d. Maintenance of a continuous output of urine following surgery is critical to prevent bladder distention and stress on the suture line.
   e. A urethral catheter and a suprapubic catheter may be in place, and the suprapubic catheter may be left in place for 2 weeks until healing occurs.
3. Cystectomy and urinary diversion (Fig. 45.8)
   a. Various surgical procedures are performed to create alternative pathways for urine collection and excretion.
   b. Urinary diversion may be performed with or without cystectomy (bladder removal).
   c. The surgery may be performed in two stages if the tumor is extensive, with the creation of the urinary diversion first and the cystectomy several weeks later.
   d. If a radical cystectomy is performed, lower extremity lymphedema may occur as a result of lymph node dissection, and impotence may occur.
4. Ileal conduit
   a. The ileal conduit is also called a *ureteroileostomy,* or Bricker's procedure.
   b. Ureters are implanted into a segment of the ileum, with the formation of an abdominal stoma.

Telegram & Insta: NCLEX_RN_Edu



Ureterostomy
Diverts urine directly to the skin surface through a ureteral-skin opening (stoma).
After ureterostomy the client must wear a pouch.
Cutaneous ureterostomy
Bilateral cutaneous ureterosigmoidostomy
Cutaneous ureteroureterostomy
Ileal reservoir
Diverts urine into a surgically created pouch or pocket that functions as a bladder. The stoma is continent and the client removes urine by regular self-catheterization.
Catheter
Continent internal ileal reservoir (Kock's pouch)
Sigmoidostomy
Diverts urine to the large intestine, so no stoma is required. The client excretes urine with bowel movements and bowel incontinence may result.
Ureterosigmoidostomy
Ureteroileosigmoidostomy
Conduit
Collects urine in a portion of the intestine, which is then opened onto the skin surface as a stoma. After the creation of a conduit, the client must wear a pouch.
Colon conduit
Ileal (Bricker's) conduit

FIG. 45.8 Urinary diversion procedures used in the treatment of bladder cancer.

c. The urine flows into the conduit and is propelled continuously out through the stoma by peristalsis.

d. The client is required to wear an appliance over the stoma to collect the urine (Box 45.18).

e. Complications include obstruction, pyelonephritis, leakage at the anastomosis site, stenosis, hydronephrosis, calculi, skin irritation and ulceration, and stomal defects.

5. Kock pouch

a. The Kock pouch is a continent internal ileal reservoir created from a segment of the ileum and ascending colon.

b. The ureters are implanted into the side of the reservoir, and a special nipple valve is constructed to attach the reservoir to the skin.

c. Postoperatively, the client will have a urinary catheter in place to drain urine continuously until the pouch has healed.

d. The urinary catheter is irrigated gently with normal saline to prevent obstruction from mucus or clots.

e. Following removal of the urinary catheter, the client is instructed in how to self-catheterize and to drain the reservoir at 4- to 6-hour intervals (Box 45.19).

Telegram & Insta: NCLEX_RN_Edu

BOX 45.18 Urinary Stoma Care

- Instruct the client to change the appliance in the morning, when urinary production is slowest.
- Collect equipment, remove collection bag, and use water or commercial solvent to loosen adhesive.
- Hold a rolled gauze pad against the stoma to collect and absorb urine during the procedure.
- Cleanse the skin around the stoma and under the drainage bag with mild nonresidue soap and water.
- Inspect the skin for excoriation, and instruct the client to prevent urine from coming into contact with the skin.
- After the skin is dry, apply skin adhesive around the appliance.
- Instruct the client to cut the stoma opening of the skin barrier just large enough to fit over the stoma (no more than 3 mm larger than the stoma).
- Instruct the client that the stoma will begin to shrink, requiring a smaller stoma opening on the skin barrier.
- Apply the skin barrier before attaching the pouch or face plate.
- Place the appliance over the stoma and secure in place.
- Encourage self-care; teach the client to use a mirror.
- Instruct the client that the pouch may be drained by a bedside bag or leg bag, especially at night.
- Instruct the client to empty the urinary collection bag when it is one-third full to prevent pulling of the appliance and leakage.
- Instruct the client to check the appliance seal if perspiring occurs.
- Instruct the client to leave the urinary pouch in place as long as it is not leaking and to change it every 5 to 7 days.
- During appliance changes, leave the skin open to air for as long as possible.
- Use a non-karaya product, because urine erodes karaya.
- To control odor, instruct the client to drink adequate fluids, wash the appliance thoroughly with soap and lukewarm water, and soak the collection pouch in dilute white vinegar for 20 to 30 minutes; a special deodorant tablet can also be placed into the pouch while it is being worn.
- Instruct the client who takes baths to keep the level of the water below the stoma and to avoid oily soaps.
- If the client plans to shower, instruct the client to direct the flow of water away from the stoma.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 1054, 1056.

BOX 45.19 Self-Irrigation and Catheterization of Stoma

Irrigation

- Instruct the client to wash hands and use clean technique.
- Instruct the client to use a catheter and syringe, instill 60 mL of normal saline or water into the reservoir, and aspirate gently or allow to drain.
- Instruct the client to irrigate until the drainage remains free of mucus but to be careful not to overirrigate.

Catheterization

- Instruct the client to wash hands and use clean technique.
- Initially, instruct the client to insert a catheter every 2 to 3 hours to drain the reservoir; during each week thereafter, increase the interval by 1 hour until catheterization is done every 4 to 6 hours.
- Lubricate the catheter well with water-soluble lubricant, and instruct the client never to force the catheter into the reservoir.
- If resistance is met, instruct the client to pause, rotate the catheter, and apply gentle pressure to insert.
- Instruct the client to notify the surgeon if the client is unable to insert the catheter.
- When urine has stopped, instruct the client to take several deep breaths and move the catheter in and out 2 to 3 inches (5 to 7.5 cm) to ensure that the pouch is empty.
- Instruct the client to withdraw the catheter slowly and pinch the catheter when withdrawn so that it does not leak urine.
- Instruct the client to keep catheterization supplies close at hand.

6. Indiana pouch
   a. A continent reservoir is created from the ascending colon and terminal ileum, making a pouch larger than the Kock pouch (additional continent reservoirs include the Mainz and Florida pouch systems).
   b. Postoperatively, care is similar to that for the Kock pouch.
7. Creation of a neobladder
   a. Creation of a neobladder is similar to creation of an internal reservoir, with the difference being that instead of emptying through an abdominal stoma, the bladder empties through a pelvic outlet into the urethra.
   b. The client empties the neobladder by relaxing the external sphincter and creating abdominal pressure or by intermittent self-catheterization.
8. Percutaneous nephrostomy or pyelostomy
   a. These procedures are used to prevent or treat obstruction.
   b. The procedures involve a percutaneous or surgical insertion of a nephrostomy tube into the kidney for drainage.
   c. Nursing interventions involve stabilizing the tube to prevent dislodgment and monitoring output.
9. Ureterostomy
   a. Ureterostomy may be performed as a palliative procedure if the ureters are obstructed by the tumor.
   b. The ureters are attached to the surface of the abdomen, where the urine flows directly into a drainage appliance without a conduit.
   c. Potential problems include infection, skin irritation, and obstruction to urinary flow as a result of strictures at the opening.

Telegram & Insta: NCLEX_RN_Edu

10. Vesicostomy
    a. The bladder is sutured to the abdomen, and a stoma is created in the bladder wall.
    b. The bladder empties through the stoma.

F. Preoperative interventions

1. Instruct the client in preoperative, operative, and postoperative management, including diet, medications, nasogastric tube placement, IV lines, NPO status, pain control, coughing and deep breathing, leg exercises, and postoperative activity.
2. Demonstrate appliance application and use for those clients who will have a stoma.
3. Arrange an enterostomal nurse consult and for a visit with a person who has had urinary diversion.
4. Administer antimicrobials for bowel preparation as prescribed.
5. Encourage discussion of feelings, including the effects on sexual activities.

G. Postoperative interventions

Monitor urinary output closely following bladder surgery. Irrigate the ureteral catheter (if present and if prescribed) gently to prevent obstruction. Follow the surgeon's prescriptions and agency policy regarding irrigation.

1. Monitor vital signs.
2. Assess incision site.
3. Assess stoma (should be red and moist) every hour for the first 24 hours.
4. Monitor for edema in the stoma, which may be present in the immediate postoperative period.
5. Notify the surgeon if the stoma appears dark and dusky (indicates necrosis).
6. Monitor for prolapse or retraction of the stoma.
7. Assess bowel function; monitor for expected return of peristalsis in 3 to 4 days.
8. Maintain NPO status as prescribed until bowel sounds return.
9. Monitor for continuous urine flow (30 to 60 mL/hr).
10. Notify the surgeon if the urine output is less than 30 mL/hr or if no urine output occurs for more than 15 minutes.
11. Ureteral stents or catheters, if present, may be in place for 2 to 3 weeks or until healing occurs; maintain stability with catheters to prevent dislodgment.
12. Monitor for hematuria.
13. Monitor for signs of peritonitis.
14. Monitor for bladder distention following a partial cystectomy.
15. Monitor for shock, hemorrhage, thrombophlebitis, and lower extremity lymphedema after a radical cystectomy.
16. Monitor the urinary drainage pouch for leaks, and check skin integrity (see Box 45.18).
17. Monitor the pH of the urine (do not place the dipstick in the stoma), because highly alkaline or acidic urine can cause skin irritation and facilitate crystal formation.
18. Instruct the client regarding the potential for urinary tract infection or the development of calculi.
19. Instruct the client to assess the skin for irritation, monitor the urinary drainage pouch, and report any leakage.
20. Encourage the client to express feelings about changes in body image, embarrassment, and sexual dysfunction.

XXV. Oncological Emergencies

A. Sepsis and disseminated intravascular coagulation (DIC)

1. Description: The client with cancer is at increased risk for infection, particularly gram-negative organisms, in the bloodstream (sepsis or **septicemia**) and for DIC, a life-threatening problem frequently associated with sepsis.
2. Interventions
    a. Prevent the complication through early identification of clients at high risk for sepsis and DIC.
    b. Maintain strict aseptic technique with the immunocompromised client, and monitor closely for infection and signs of bleeding.
    c. Administer antibiotics intravenously as prescribed.
    d. Administer anticoagulants as prescribed during the early phase of DIC.
    e. Administer cryoprecipitated clotting factors, as prescribed, when DIC progresses and hemorrhage is the primary problem.

Notify the PHCP immediately if signs of an oncological emergency occur.

B. Syndrome of inappropriate antidiuretic hormone (SIADH)

1. Description
    a. Tumors can produce, secrete, or stimulate substances that mimic antidiuretic hormone.
    b. Mild symptoms include weakness, muscle cramps, loss of appetite, and fatigue; serum **sodium** levels range from 115 to 120 mEq/L (115 to 120 mmol/L).
    c. More serious signs and symptoms relate to water intoxication and include weight gain, personality changes, confusion, and extreme muscle weakness.
    d. As the serum sodium level approaches 110 mEq/L (110 mmol/L), seizures, coma, and eventually death will occur unless the condition is treated rapidly.

Telegram & Insta: NCLEX_RN_Edu

2. Interventions
   a. Initiate fluid restriction and increased sodium intake as prescribed.
   b. As prescribed, administer an antagonist to antidiuretic hormone.
   c. Monitor serum sodium levels.
   d. Treat the underlying cause with chemotherapy or radiation to achieve tumor regression.

C. Spinal cord compression (see Clinical Judgment: Analyze Cues Box)
1. Description
   a. Spinal cord compression occurs when a tumor directly enters the spinal cord or when the vertebral column collapses from tumor entry, impinging on the spinal cord.
   b. Spinal cord compression causes back pain, usually before neurological deficits occur.
   c. Neurological deficits relate to the spinal level of compression and include numbness; tingling; loss of urethral, vaginal, and rectal sensation; and muscle weakness.
2. Interventions
   a. Early recognition: Assess for back pain and neurological deficits.
   b. Administer high-dose corticosteroids to reduce swelling around the spinal cord and relieve symptoms.
   c. Prepare the client for immediate radiation and/or chemotherapy to reduce the size of the tumor and relieve compression.
   d. Surgery may need to be performed to remove the tumor and relieve the pressure on the spinal cord.
   e. Instruct the client in the use of neck or back braces if they are prescribed.

CLINICAL JUDGMENT: ANALYZE CUES

A client with breast cancer had bilateral mastectomies 3 years ago. Since then the client has been receiving radiation and chemotherapy treatments to treat the cancer. Over the past year diagnostic studies revealed metastasis to the lungs, bones and pelvis, and the liver. The client has been experiencing a great deal of pain and is receiving pain medication to control it. Today the client calls the clinic nurse and reports severe pain in the back, inability to sit up or move around, and that the pain medication is ineffective. The client is also experiencing muscle weakness and numbness and tingling in the legs. The nurse analyzes the cues and suspects that the client has spinal cord compression. This is an oncological emergency, and the client needs medical attention immediately.

D. Hypercalcemia
1. Description
   a. Hypercalcemia is a late manifestation of extensive malignancy that occurs most often with bone metastasis, when the bone releases calcium into the bloodstream.
   b. Decreased physical mobility contributes to or worsens hypercalcemia.
   c. Early signs include fatigue, anorexia, nausea, vomiting, constipation, and polyuria.
   d. More serious signs and symptoms include severe muscle weakness, diminished deep tendon reflexes, paralytic ileus, dehydration, and changes in the electrocardiogram.
2. Interventions
   a. Monitor serum calcium level and electrocardiographic changes.
   b. Administer oral or parenteral fluids as prescribed.
   c. Administer medications that lower the calcium level and control nausea and vomiting as prescribed.
   d. Prepare the client for dialysis if the condition becomes life-threatening or is accompanied by renal impairment.
   e. Encourage walking to prevent breakdown of bone.

E. Superior vena cava syndrome
1. Description
   a. Superior vena cava (SVC) syndrome occurs when the SVC is compressed or obstructed by tumor growth (commonly associated with lung cancer and lymphoma).
   b. Signs and symptoms result from blockage of blood flow in the venous system of the head, neck, and upper trunk.
   c. Early signs and symptoms generally occur in the morning and include edema of the face, especially around the eyes, and tightness of the shirt or blouse collar (Stokes' sign).
   d. As the condition worsens, edema in the arms and hands, dyspnea, erythema of the upper body, swelling of the veins in the chest and neck, and epistaxis occur.
   e. Life-threatening signs and symptoms include airway obstruction, hemorrhage, cyanosis, mental status changes, decreased cardiac output, and hypotension.
2. Interventions
   a. Assess for early signs and symptoms of SVC syndrome.
   b. Place the client in semi-Fowler's position, and administer corticosteroids and diuretics as prescribed.
   c. Prepare the client for high-dose radiation therapy to the mediastinal area and possible surgery to insert a metal stent in the vena cava.

Telegram & Insta: NCLEX_RN_Edu

F. Tumor lysis syndrome
- **1.** Description
  - **a.** Tumor lysis syndrome occurs when large quantities of tumor cells are destroyed rapidly and intracellular components such as potassium and uric acid are released into the bloodstream faster than the body can eliminate them.
  - **b.** Tumor lysis syndrome can indicate that cancer treatment is destroying tumor cells; however, if left untreated, it can cause severe tissue damage and death.
  - **c.** Hyperkalemia, hyperphosphatemia with resultant hypocalcemia, and hyperuricemia occur; hyperuricemia can lead to acute kidney injury.
- **2.** Interventions
  - **a.** Encourage oral hydration; IV hydration may be prescribed; monitor renal function and intake and output, and ensure that the client is on a renal diet low in potassium and phosphorus.
  - **b.** Monitor weight and electrolyte values.
  - **c.** Administer diuretics to increase the urine flow through the kidneys as prescribed.
  - **d.** Administer medications that increase the excretion of purines, such as allopurinol, as prescribed.
  - **e.** Prepare to administer IV infusion of glucose and insulin to treat hyperkalemia.
  - **f.** Prepare the client for dialysis if hyperkalemia and hyperuricemia persist despite treatment.

XXVI. Anemia

A. Description
- **1.** Condition in which the blood lacks adequate healthy red blood cells or hemoglobin, with most common causes being acute blood loss, decreased or faulty red blood cell production, or the destruction of red blood cells
- **2.** There are several types of anemia, with the main types being anemia related to acute and chronic blood loss, anemia of chronic diseases (including cancers, immunodeficiency syndrome, renal disease, liver diseases, and autoimmune conditions), anemias caused by nutritional deficiencies (such as iron, folate, or vitamin B_{12} deficiency), and hereditary anemias (including sickle cell anemia and thalassemia).
- **3.** Treatment of anemia focuses on treating the cause of the condition and varies based on the type of anemia.
- **4.** Acute blood loss anemia is characterized by normal red blood cell size, shape, and color. Clients at risk include postoperative clients, clients with an active bleeding problem, or immunocompromised clients with a reduction in blood components. Hemoglobin, hematocrit, or red blood cell levels can be low.

B. Assessment
- **1.** Fatigue
- **2.** Weakness
- **3.** Pallor or slight jaundice if red blood cell destruction occurs
- **4.** Shortness of breath
- **5.** Dysrhythmias
- **6.** Chest pain
- **7.** Tachycardia
- **8.** Cool extremities

C. Interventions
- **1.** Administer blood products and hematopoietic medications as prescribed to treat anemia related to acute and chronic conditions.
- **2.** Encourage a diet rich in the deficient nutrient, such as supplementation with iron, folate, or vitamin B_{12}, if the anemia is caused by malnutrition.
- **3.** Control and address the source of bleeding if anemia is caused by acute blood loss, and assess client for sources of frank and occult bleeding. Contact the PHCP and prepare for replacement therapy if acute blood loss occurs.

XXVII. Iron-Deficiency Anemia

A. Description
- **1.** Iron stores are depleted, resulting in a decreased iron supply for the manufacture of hemoglobin in red blood cells.
- **2.** Commonly results from blood loss, increased metabolic demands, syndromes of gastrointestinal malabsorption, and dietary inadequacy.
- **3.** Older clients often have poor diets or chewing difficulties that place them at risk for anemias.

B. Assessment
- **1.** Pallor
- **2.** Weakness and fatigue
- **3.** Low hemoglobin, hematocrit, and mean cellular volume (MCV) levels
- **4.** Red blood cells that are microcytic and hypochromic

C. Interventions
- **1.** Increase oral intake of iron, and instruct client in food choices that are high in iron (see Box 11.2 in Chapter 11 for iron-rich foods).
- **2.** Administer iron supplements as prescribed.
- **3.** Intramuscular injections of iron (using Z-track method) or IV administration of iron may be prescribed in severe cases of anemia.
- **4.** Teach clients how to administer the iron supplements.
  - **a.** Take between meals for maximum absorption.
  - **b.** Take with a multivitamin or fruit juice, such as tomato juice, because vitamin C increases absorption.
  - **c.** Do not take with milk or antacids, because these items decrease absorption.

Telegram & Insta: NCLEX_RN_Edu

d. Instruct the client about the side effects of iron supplements (black stools, constipation, and foul aftertaste).

e. Liquid iron preparations stain the teeth. Teach the client that liquid iron should be taken through a straw and that the teeth should be brushed after administration.

XXVIII. Vitamin B_{12}–Deficiency Anemia

A. Description

1. A macrocytic anemia that results from an inadequate intake of vitamin B_{12} or lack of absorption of ingested vitamin B_{12} from the intestinal tract

2. Pernicious anemia results from a deficiency of intrinsic factor (normally secreted by the gastric mucosa), necessary for intestinal absorption of vitamin B_{12}; gastric disease or surgery can result in a lack of intrinsic factor.

B. Assessment

1. Severe pallor

2. Fatigue

3. Weight loss

4. Smooth, beefy red tongue

5. Slight jaundice

6. Paresthesias of the hands and feet

7. Disturbances with gait and balance

C. Interventions

1. Increase dietary intake of foods rich in vitamin B_{12}, such as meat and liver, if the anemia is a result of a dietary deficiency.

2. Administer vitamin B_{12} injections as prescribed, weekly initially and then monthly for maintenance (lifelong) if the anemia is the result of a deficiency of intrinsic factor or disease or surgery of the ileum.

3. Oral B_{12} preparations and nasal spray or sublingual cobalamin preparations may be prescribed to maintain vitamin level.

XXIX. Folate-Deficiency Anemia

A. Description

1. A macrocytic anemia in which red blood cells are larger than normal and are oval-shaped rather than round-shaped due to the lack of inadequate intake of folate (vitamin B_9).

2. Folic acid is required for red blood cell formation and maturation.

3. Common causes include dietary deficiency; malabsorption syndromes such as celiac disease, Crohn's disease, or small bowel resection; medications (such as antiseizure medications) that decrease the absorption of folic acid; a condition (including pregnancy) that increases the requirement of folic acid; chronic alcoholism; and chronic hemodialysis.

B. Assessment

1. Dyspepsia

2. Smooth, beefy red tongue

3. Pallor, fatigue, and weakness

4. Tinnitus

5. Tachycardia

C. Interventions

1. Encourage the client to eat foods rich in folic acid, such as green leafy vegetables, meat, liver, fish, legumes, peanuts, orange juice, and avocado.

2. Administer folic acid as prescribed.

XXX. Sickle Cell Anemia: See Chapter 31 for more information regarding sickle cell anemia.

XXXI. Thalassemia: See Chapter 31 for more information regarding thalassemia.

XXXII. Aplastic Anemia

A. Description

1. Aplastic anemia is a deficiency of circulating erythrocytes and all other formed elements of blood, resulting from the arrested development of cells within the bone marrow.

2. It can be primary (present at birth) or secondary (acquired).

3. Several possible causes exist, including chronic exposure to myelotoxic agents, viruses and infections such as hepatitis, Epstein-Barr virus, autoimmune disorders such as human immunodeficiency virus, and allergic states.

4. The definitive diagnosis is determined by bone marrow aspiration (shows conversion of red bone marrow to fatty bone marrow).

5. Therapeutic management focuses on restoring function to the bone marrow and involves immunosuppressive therapy and bone marrow transplantation (treatment of choice if a suitable donor exists).

6. If the cause is a myelotoxic medication that is being administered for another purpose, the medication may be discontinued to improve bone marrow function.

B. Assessment

1. Pancytopenia (deficiency of erythrocytes, leukocytes, and thrombocytes)

2. Petechiae, purpura, bleeding, pallor, weakness, tachycardia, and fatigue

C. Interventions

1. Prepare the client for bone marrow transplantation if planned.

2. Administer immunosuppressive medications as prescribed; antilymphocyte globulin or antithymocyte globulin may be prescribed to suppress the autoimmune response.

3. Colony-stimulating factors may be prescribed to enhance bone marrow production.

4. Corticosteroids and cyclosporine may be prescribed.

Telegram & Insta: NCLEX_RN_Edu

5. Administer blood transfusions if prescribed and monitor for transfusion reactions. Note that transfusions could increase the chance for developing immune reactions to platelets and shorten the life span of transfused cells. This therapy is discontinued as soon as the bone marrow begins to produce RBCs if the problem is transient.

PRACTICE QUESTIONS

1. The nurse is reviewing the laboratory results of a client diagnosed with multiple myeloma. Which would the nurse expect to note specifically in this disorder?
   1. Increased calcium level
   2. Increased white blood cells
   3. Decreased blood urea nitrogen level
   4. Decreased number of plasma cells in the bone marrow

2. The nurse is creating a plan of care for the client with multiple myeloma and includes which **priority** intervention in the plan?
   1. Encouraging fluids
   2. Providing frequent oral care
   3. Coughing and deep breathing
   4. Monitoring the red blood cell count

3. When caring for a client with cervical cancer who has an internal radiation implant, the nurse would observe which principles? **Select all that apply.**
   - ❑ 1. Limiting the time with the client to 1 hour per shift.
   - ❑ 2. Keeping pregnant persons out of the client's room.
   - ❑ 3. Placing the client in a private room with a private bath.
   - ❑ 4. Wearing a lead shield when providing direct client care.
   - ❑ 5. Removing the dosimeter film badge when entering the client's room.
   - ❑ 6. Allowing individuals younger than 16 years old in the room as long as they are 6 feet away from the client.

4. While giving care to a client with cervical cancer who has an internal cervical radiation implant, the nurse finds the implant in the bed. The nurse would take which **initial** action?
   1. Call the primary health care provider (PHCP).
   2. Reinsert the implant into the vagina.
   3. Pick up the implant with gloved hands and flush it down the toilet.
   4. Pick up the implant with long-handled forceps and place it in a lead container.

5. The nurse would plan to implement which intervention in the care of a client experiencing neutropenia as a result of chemotherapy?
   1. Restrict all visitors.
   2. Restrict fluid intake.
   3. Teach the client and family about the need for hand hygiene.
   4. Insert an indwelling urinary catheter to prevent skin breakdown.

6. The home health care nurse is caring for a client with cancer who is complaining of acute pain. The **most appropriate** determination of the client's pain needs to include which assessment?
   1. The client's pain rating
   2. Nonverbal cues from the client
   3. The nurse's impression of the client's pain
   4. Pain relief after appropriate nursing intervention

7. The nurse is caring for a client who is postoperative following a pelvic exenteration, and the surgeon changes the client's diet from NPO (nothing by mouth) status to clear liquids. The nurse would check which **priority** item before administering the diet?
   1. Bowel sounds
   2. Ability to ambulate
   3. Incision appearance
   4. Urine specific gravity

8. A client is admitted to the hospital with a suspected diagnosis of Hodgkin's disease. Which assessment finding would the nurse expect to note specifically in the client?
   1. Fatigue
   2. Weakness
   3. Weight gain
   4. Enlarged lymph nodes

9. During the admission assessment of a client with advanced ovarian cancer, the nurse recognizes which manifestation as typical of the disease?
   1. Diarrhea
   2. Hypermenorrhea
   3. Abnormal bleeding
   4. Abdominal distention

10. The nurse is caring for a client with lung cancer and bone metastasis. What signs and symptoms would the nurse recognize as indications of a possible oncological emergency? **Select all that apply.**
    - ❑ 1. Facial edema in the morning
    - ❑ 2. Weight loss of 20 lb (9 kg) in 1 month
    - ❑ 3. Serum calcium level of 12 mg/dL (3.0 mmol/L)

Telegram & Insta: NCLEX_RN_Edu

❑ 4. Serum sodium level of 136 mg/dL (136 mmol/L)
❑ 5. Serum potassium level of 3.4 mg/dL (3.4 mmol/L)
❑ 6. Numbness and tingling of the lower extremities

11. A client who has been receiving radiation therapy for bladder cancer states to the nurse, "I feel like I am urinating through my vagina." The nurse interprets that the client may be experiencing which condition?
1. Rupture of the bladder
2. The development of a vesicovaginal fistula
3. Extreme stress caused by the diagnosis of cancer
4. Altered perineal sensation as a side effect of radiation therapy

12. The nurse is instructing a client to perform a testicular self-examination (TSE). The nurse would provide the client with which information about the procedure?
1. To examine the testicles while lying down
2. That the best time for the examination is after a shower
3. To gently feel the testicle with one finger to feel for a growth
4. That TSEs should be done at least every 6 months

13. The nurse is conducting a history and monitoring laboratory values on a client with multiple myeloma. What assessment findings would the nurse expect to note? **Select all that apply.**
❑ 1. Pathological fracture
❑ 2. Urinalysis positive for Bence Jones protein
❑ 3. Hemoglobin level of 15.5 g/dL (155 mmol/L)
❑ 4. Calcium level of 9.0 mg/dL (2.25 mmol/L)
❑ 5. Serum creatinine level of 2.0 mg/dL (176.6 mcmol/L)

14. A gastrectomy is performed on a client with gastric cancer. In the immediate postoperative period, the nurse notes bloody drainage from the nasogastric tube. The nurse would take which **most appropriate** action?
1. Measure abdominal girth.
2. Irrigate the nasogastric tube.
3. Continue to monitor the drainage.
4. Notify the surgeon.

15. The nurse is teaching a client about the risk factors associated with colorectal cancer. The nurse determines that **further teaching is necessary** related to colorectal cancer if the client identifies which item as an associated risk factor?
1. Age younger than 50 years
2. History of colorectal polyps
3. Family history of colorectal cancer
4. Chronic inflammatory bowel disease

16. The nurse is assessing the perineal wound in a client who has returned from the operating room following an abdominal perineal resection and notes serosanguineous drainage from the wound. Which nursing action is **most appropriate**?
1. Clamp the surgical drain.
2. Change the dressing as prescribed.
3. Notify the surgeon.
4. Remove and replace the perineal packing.

17. The nurse is assessing the colostomy of a client who has had an abdominal perineal resection for a bowel tumor. Which assessment finding indicates that the colostomy is beginning to function?
1. The passage of flatus
2. Absent bowel sounds
3. The client's ability to tolerate food
4. Bloody drainage from the colostomy

18. The nurse is reviewing the history of a client with bladder cancer. The nurse expects to note documentation of which **most** common sign or symptom of this type of cancer?
1. Dysuria
2. Hematuria
3. Urgency on urination
4. Frequency of urination

19. The nurse is assessing a client who has a new ureterostomy. Which statement by the client indicates the **need for more education** about urinary stoma care?
1. "I change my pouch every week."
2. "I change the appliance in the morning."
3. "I empty the urinary collection bag when it is two-thirds full."
4. "When I'm in the shower, I direct the flow of water away from my stoma."

20. A client with carcinoma of the lung develops syndrome of inappropriate antidiuretic hormone (SIADH) as a complication of the cancer. The nurse anticipates that the primary health care provider will request which prescriptions? **Select all that apply.**
❑ 1. Radiation
❑ 2. Chemotherapy
❑ 3. Increased fluid intake
❑ 4. Decreased oral sodium intake
❑ 5. Serum sodium level determination
❑ 6. Medication that is antagonistic to antidiuretic hormone

Telegram & Insta: NCLEX_RN_Edu

21. The nurse is monitoring a client for signs and symptoms related to superior vena cava syndrome. Which is an **early** sign of this oncological emergency?
1. Cyanosis
2. Arm edema
3. Periorbital edema
4. Mental status changes

22. The nurse manager is teaching the nursing staff about signs and symptoms related to hypercalcemia in a client with metastatic prostate cancer and tells the staff that which is a **late** sign or symptom of this oncological emergency?
1. Headache
2. Dysphagia
3. Constipation
4. Electrocardiographic changes

23. As part of chemotherapy education, the nurse teaches a client about the risk for bleeding and self-care during the period of greatest bone marrow suppression (the nadir). The nurse understands that **further teaching is needed** if the client makes which statement?
1. "I should avoid blowing my nose."
2. "I may need a platelet transfusion if my platelet count is too low."
3. "I'm going to take aspirin for my headache as soon as I get home."
4. "I will count the number of pads and tampons I use when menstruating."

24. The community health nurse is instructing a group of young clients about breast self-examination. The nurse would instruct the clients to perform the examination at which time?
1. At the onset of menstruation
2. Every month during ovulation
3. Weekly at the same time of day
4. One week after menstruation begins

25. A client is diagnosed as having a intestinal tumor. The nurse would monitor the client for which complications of this type of tumor? **Select all that apply.**
- ❑ 1. Flatulence
- ❑ 2. Peritonitis
- ❑ 3. Hemorrhage
- ❑ 4. Fistula formation
- ❑ 5. Bowel perforation
- ❑ 6. Lactose intolerance

26. The nurse is caring for a client after a mastectomy. Which nursing intervention would assist in preventing lymphedema of the affected arm?
1. Placing cool compresses on the affected arm
2. Elevating the affected arm on a pillow above heart level
3. Avoiding arm exercises in the immediate postoperative period
4. Maintaining an intravenous site below the antecubital area on the affected side

27. The nurse is providing dietary teaching for a client with a diagnosis of chronic gastritis who is at risk for vitamin B_{12} deficiency. The nurse instructs the client to include which foods rich in vitamin B_{12} in the diet? **Select all that apply.**
- ❑ 1. Meat
- ❑ 2. Corn
- ❑ 3. Liver
- ❑ 4. Apples
- ❑ 5. Bananas

28. The nurse is instructing a client with iron-deficiency anemia regarding the administration of a liquid oral iron supplement. Which instruction would the nurse tell the client?
1. Administer the iron at mealtimes.
2. Administer the iron through a straw.
3. Mix the iron with cereal to administer.
4. Add the iron to apple juice for easy administration.

29. Laboratory studies are performed for a client suspected to have iron-deficiency anemia. The nurse reviews the laboratory results, knowing that which result indicates this type of anemia?
1. Elevated hemoglobin level
2. Decreased reticulocyte count
3. Elevated red blood cell count
4. Red blood cells that are microcytic and hypochromic

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 1

Rationale: Findings indicative of multiple myeloma are an increased number of plasma cells in the bone marrow, anemia, hypercalcemia caused by the release of calcium from the deteriorating bone tissue, and an elevated blood urea nitrogen level. An increased white blood cell count may or may not be present and is not related specifically to multiple myeloma.

Test-Taking Strategy: Focus on the **subject,** laboratory findings in multiple myeloma. Noting the name of the disorder and recalling the pathophysiology of the disease and that proliferation of plasma cells in the bone occurs will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 645.

2. *Answer:* 1

Rationale: Hypercalcemia caused by bone destruction is a priority concern in the client with multiple myeloma. The nurse would administer fluids in adequate amounts to maintain a urine output of 1.5 to 2 L/day; this requires about 3 L of fluid intake per day. The fluid is needed not only to dilute the calcium overload but also to prevent protein from precipitating in the renal tubules. Options 2, 3, and 4 may be components of the plan of care but are not the priority in this client.

Test-Taking Strategy: Note the **strategic word,** *priority*. Recalling the pathophysiology of this disorder and that hypercalcemia can occur will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 646.

3. *Answer:* 2, 3, 4

Rationale: The time that the nurse spends in the room of a client with an internal radiation implant is 30 minutes per shift. The client must be placed in a private room with a private bath. Lead shielding can be used to reduce the transmission of radiation. The dosimeter film badge must be worn when in the client's room. Children younger than 16 years of age and pregnant individuals are not allowed in the client's room.

Test-Taking Strategy: Focus on the **subject,** radiation precautions. Recalling the time frame related to exposure to the client will assist in eliminating option 1. From the remaining options, select the correct options because of the possible risks associated with exposure to radiation.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 381, 388.

4. *Answer:* 4

Rationale: In the event that a radiation source becomes dislodged, the nurse would first encourage the client to lie still until the radioactive source has been placed in a safe, closed container. The nurse would use long-handled forceps to place the source in the lead container that should be in the client's room. The nurse would then call the radiation oncologist and document the event and the actions taken. It is not within the scope of nursing practice to insert a radiation implant.

Test-Taking Strategy: Note the **strategic word,** *initial*. The initial action would be to prevent self-contamination from radiation exposure. This will direct you to the correct option.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. p. 381.

5. *Answer:* 3

Rationale: In the neutropenic client, meticulous hand hygiene education is implemented for the client, family, visitors, and staff. Not all visitors are restricted, but the client is protected from persons with known infections. Fluids need to be encouraged. Invasive measures such as an indwelling urinary catheter need to be avoided to prevent infections.

Test-Taking Strategy: Eliminate option 1 because of the **closed-ended word** *all*. Next, eliminate option 2 because it is not reasonable to restrict fluids in a client receiving chemotherapy who is at risk for fluid and electrolyte imbalances. Eliminate option 4 because of the risk of infection that exists with this measure.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. p. 388.

6. *Answer:* 1

Rationale: The client's self-report is a critical component of pain assessment. The nurse needs to ask the client to describe the pain and listen carefully to the words the client uses to describe the pain. Nonverbal cues from the client are important but are not the most appropriate pain assessment measure. The nurse's impression of the client's pain is inappropriate in determining the client's level of pain. Assessing pain relief is an important measure, but this option is not related to the subject of the question.

Test-Taking Strategy: Note the **strategic words,** *most appropriate*. Eliminate option 3 because the nurse is not the client of the question. From the remaining options, the subjective data from the client will provide the most accurate description of the pain.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 107-108.

7. *Answer:* 1

Rationale: The client is kept NPO until peristalsis returns, usually in 4 to 6 days. When signs of bowel function return, clear fluids are given to the client. If no distention occurs, the diet is advanced as tolerated. The most important assessment is to assess bowel sounds before feeding the client. Options 2, 3, and 4 are unrelated to the data in the question.

Test-Taking Strategy: Note the **strategic word,** *priority*, and the words *NPO status to clear liquids* in the question. The correct option is the only one that relates to gastrointestinal function.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 340-341.

Telegram & Insta: NCLEX_RN_Edu

8. *Answer:* 4

Rationale: Hodgkin's disease is a chronic progressive neoplastic disorder of lymphoid tissue characterized by the painless enlargement of lymph nodes with progression to extralymphatic sites, such as the spleen and liver. Weight loss is most likely to be noted. Fatigue and weakness may occur but are not related specifically to the disease.

Test-Taking Strategy: Options 1 and 2 are **comparable or alike** and are rather vague symptoms that can occur in many disorders. Option 3 can be eliminated because, in such a disorder, weight loss is most likely to occur. Also, recalling that Hodgkin's disease affects the lymph nodes will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 640-642.

9. *Answer:* 4

Rationale: Clinical manifestations of ovarian cancer include abdominal distention, urinary frequency and urgency, pleural effusion, malnutrition, pain from pressure caused by the growing tumor and the effects of urinary or bowel obstruction, constipation, ascites with dyspnea, and ultimately general severe pain. Abnormal bleeding, often resulting in hypermenorrhea, is associated with uterine cancer.

Test-Taking Strategy: Eliminate options 2 and 3 first because they are **comparable or alike**. From the remaining options, consider the anatomical location of the cancer. This will assist in directing you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 1243-1244.

10. *Answer:* 1, 3, 6

Rationale: Oncological emergencies include sepsis, disseminated intravascular coagulation, syndrome of inappropriate antidiuretic hormone, spinal cord compression, hypercalcemia, superior vena cava syndrome, and tumor lysis syndrome. Blockage of blood flow to the venous system of the head resulting in facial edema is a sign of superior vena cava syndrome. A serum calcium level of 12 mg/dL (3.0 mmol/L) indicates hypercalcemia. Numbness and tingling of the lower extremities could be a sign of spinal cord compression. Mild hypokalemia and weight loss are not oncological emergencies. A sodium level of 136 mg/dL (136 mmol/L) is a normal level.

Test-Taking Strategy: Note the **subject,** an oncological emergency. Recalling the signs and symptoms of oncological emergencies will help you identify the correct options. Also, recalling the normal calcium, potassium, and sodium levels will direct you to the correct options.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 261.

11. *Answer:* 2

Rationale: A vesicovaginal fistula is a genital fistula that occurs between the bladder and vagina. The fistula is an abnormal opening between these two body parts; if this occurs, the client may experience drainage of urine through the vagina. The client's complaint is not associated with options 1, 3, or 4.

Test-Taking Strategy: Focus on the **subject,** a complication of bladder cancer and the **data in the question.** Noting the words *voiding through the vagina* should direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 1248-1249.

12. *Answer:* 2

Rationale: The TSE is recommended monthly after a warm bath or shower when the scrotal skin is relaxed. The client should stand to examine the testicles. Using both hands, with fingers under the scrotum and thumbs on top, the client needs to gently roll the testicles, feeling for any lumps.

Test-Taking Strategy: Focus on the **subject,** the procedure for performing TSE. Eliminate option 4 first because of the words *6 months*. Next, eliminate option 3 because of the word *one*. From the remaining options, eliminate option 1 by trying to visualize the process of the self-examination.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Saunders. pp. 1485-1486.

13. *Answer:* 1, 2, 5

Rationale: Multiple myeloma is a B cell neoplastic condition characterized by abnormal malignant proliferation of plasma cells and the accumulation of mature plasma cells in the bone marrow. The client with multiple myeloma may experience pathological fractures, hypercalcemia, anemia, recurrent infections, and renal failure. In addition, Bence Jones proteinuria is a finding. A serum calcium level of 9.0 mg/dL (2.25 mmol/L) and a hemoglobin level of 15.5 g/dL (155 mmol/L) are normal values. A serum creatinine level of 2.0 mg/dL (176.6 mcmol/L) is elevated, indicating a renal problem.

Test-Taking Strategy: Focus on the **subject,** characteristics of multiple myeloma. Think about the pathophysiology of the disorder, and analyze the values given to direct you to the correct options.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Saunders. pp. 814-815.

14. *Answer:* 3

Rationale: Following gastrectomy, drainage from the nasogastric tube is normally bloody for 24 hours postoperatively, changes to brown-tinged, and is then yellow or clear. Because bloody drainage is expected in the immediate postoperative period, the nurse needs to continue to monitor the drainage. The nurse does not need to notify the surgeon at this time. Abdominal girth is measured to detect the development of distention. Following gastrectomy, a nasogastric tube would not be irrigated unless there are specific surgeon prescriptions to do so.

Test-Taking Strategy: Note the **strategic words,** *most appropriate*, and focus on the **subject,** the immediate postoperative period. This will direct you to the correct option. Remember

Telegram & Insta: NCLEX_RN_Edu

that drainage from the nasogastric tube is normally bloody for 24 hours postoperatively, changes to brown-tinged, and then to yellow or clear.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 861-862.

15. *Answer:* 1
Rationale: Colorectal cancer risk factors include age older than 50 years, a family history of the disease, colorectal polyps, and chronic inflammatory bowel disease.
Test-Taking Strategy: Note the **strategic words,** *further teaching is necessary*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Noting the words *younger than* in option 1 will direct you to this option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 948.

16. *Answer:* 2
Rationale: Immediately after surgery, profuse serosanguineous drainage from the perineal wound is expected. Therefore, the nurse would change the dressing as prescribed. A surgical drain would not be clamped, because this action will cause the accumulation of drainage within the tissue. The nurse does not need to notify the surgeon at this time. Drains and packing are removed gradually over a period of 5 to 7 days as prescribed. The nurse would not remove the perineal packing.
Test-Taking Strategy: Note the **strategic words,** *most appropriate*. Eliminate options 1 and 4, knowing that these are inappropriate interventions. Recalling that serosanguineous drainage is expected following this type of surgery will assist in directing you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11 ed.). St. Louis: Mosby. pp. 342-343, 956.

17. *Answer:* 1
Rationale: Following abdominal perineal resection, the nurse would expect the colostomy to begin to function within 72 hours after surgery, although it may take up to 5 days. The nurse would assess for a return of peristalsis, listen for bowel sounds, and check for the passage of flatus. Absent bowel sounds would not indicate the return of peristalsis. The client would remain NPO (nothing by mouth) until bowel sounds return and the colostomy is functioning. Bloody drainage is not expected from a colostomy.
Test-Taking Strategy: Focus on the **subject,** the colostomy beginning to function. This will assist in eliminating option 2. Knowledge of general postoperative measures will assist in eliminating option 3. Focus on the **subject** to assist in eliminating option 4 as a correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 954-956.

18. *Answer:* 2
Rationale: The most common sign in clients with cancer of the bladder is hematuria. The client also may experience irritative voiding symptoms such as frequency, urgency, and dysuria, and these symptoms often are associated with carcinoma in situ. Dysuria, urgency, and frequency of urination are also symptoms of a bladder infection.
Test-Taking Strategy: Focus on the **subject,** bladder cancer, and note the **strategic word,** *most*. Options 1, 3, and 4 are symptoms that are associated most often with bladder infection.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 1044, 1065.

19. *Answer:* 3
Rationale: The urinary collection bag needs to be changed when it is one-third full to prevent pulling of the appliance and leakage. The remaining options identify correct statements about the care of a urinary stoma.
Test-Taking Strategy: Note the **strategic words,** *need for more education*. These words indicate a **negative event query** and therefore eliminate the options that indicate client understanding. Noting the words *two-thirds full* will assist in directing you to the correct option.
Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Mosby. p. 1171.

20. *Answer:* 1, 2, 5, 6
Rationale: Cancer is a common cause of SIADH. In SIADH, excessive amounts of water are reabsorbed by the kidney and put into the systemic circulation. The increased water causes hyponatremia (decreased serum sodium levels) and some degree of fluid retention. The syndrome is managed by treating the condition and cause and usually includes fluid restriction, increased sodium intake, and medication with a mechanism of action that is antagonistic to antidiuretic hormone. Sodium levels are monitored closely because hypernatremia can develop suddenly as a result of treatment. The immediate institution of appropriate cancer therapy, usually radiation or chemotherapy, can cause tumor regression so that antidiuretic hormone synthesis and release processes return to normal.
Test-Taking Strategy: Focus on the **subject,** treatment for SIADH, and recall that in SIADH excessive amounts of water are reabsorbed by the kidney and put into the systemic circulation. This will assist in answering this question.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 397, 1236-1238.

21. *Answer:* 3
Rationale: Superior vena cava syndrome occurs when the superior vena cava is compressed or obstructed by tumor growth. Early signs and symptoms generally occur in the morning and include edema of the face, especially around the eyes, and client complaints of tightness of a shirt or blouse collar. As the compression worsens, the client experiences edema of the hands and arms. Cyanosis and mental status changes are late signs.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Note the **strategic word,** *early*. Think about the pathophysiology associated with this disorder and focus on the strategic word to assist in eliminating options 1, 2, and 4.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 388-389.

22. *Answer:* 4
Rationale: Hypercalcemia is a manifestation of bone metastasis in late-stage cancer. Headache and dysphagia are not associated with hypercalcemia. Constipation may occur early in the process. Electrocardiogram changes include shortened ST segment and a widened T wave.
Test-Taking Strategy: Note the **strategic word,** *late*. Focus on the name of the oncological emergency, *hypercalcemia,* to direct you to the correct option. Eliminate options 1 and 2 because they are not signs of hypercalcemia. Eliminate option 3 because it is an early sign of hypercalcemia.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. p. 398.

23. *Answer:* 3
Rationale: During the period of greatest bone marrow suppression (the nadir), the platelet count may be low, less than 20,000 cells mm^3 (20.0×10^9/L). The correct option describes an incorrect statement by the client. Aspirin and nonsteroidal antiinflammatory drugs and products that contain aspirin need to be avoided because of their antiplatelet activity. Options 1, 2, and 4 are correct statements by the client to prevent and monitor bleeding.
Test-Taking Strategy: Note the **strategic words,** *further teaching is needed*. These words indicate a **negative event query** and the need to select the incorrect measure about self-care and preventing bleeding. Recalling the effects of bone marrow suppression will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 248.

24. *Answer:* 4
Rationale: The breast self-examination needs to be performed regularly, 7 days after the onset of the menstrual period. Performing the examination weekly is not recommended. At the onset of menstruation and during ovulation, hormonal changes occur that may alter breast tissue.
Test-Taking Strategy: Option 3 can be eliminated easily because of the word *weekly*. Eliminate options 1 and 2 next because they are **comparable or alike** in the similarity that exists regarding the hormonal changes that occur during these times.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 1436-1437.

25. *Answer:* 2, 3, 4, 5
Rationale: Complications of intestinal tumors include bowel perforation, which can result in hemorrhage and peritonitis. Other complications include bowel obstruction and fistula formation. Flatulence can occur but is not a complication; lactose intolerance also is not a complication of intestinal tumor.
Test-Taking Strategy: Focus on the **subject,** complications of an intestinal tumor. Think about the location and pathophysiology associated with this type of tumor to answer correctly.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 949.

26. *Answer:* 2
Rationale: Following mastectomy, the arm needs to be elevated above the level of the heart. Simple arm exercises should be encouraged. No blood pressure readings, injections, intravenous lines, or blood draws would be performed on the affected arm. Cool compresses are not a suggested measure to prevent lymphedema from occurring.
Test-Taking Strategy: Focus on the **subject,** preventing lymphedema. Note the relationship between the words *lymphedema* in the question and *elevating* in the correct option. Also, using general principles related to gravity will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 1443-1443.

27. *Answer:* 1, 3
Rationale: Chronic gastritis causes deterioration and atrophy of the lining of the stomach, leading to the loss of function of the parietal cells. The source of intrinsic factor is lost, which results in an inability to absorb vitamin B_{12}, leading to development of pernicious anemia. Clients must increase their intake of vitamin B_{12} by increasing consumption of foods rich in this vitamin, such as meats and liver.
Test-Taking Strategy: Focus on the **subject,** foods rich in vitamin B_{12}. Note that apples and bananas are **comparable or alike** in that they are fruits. This will help you eliminate these options first. Option 2 can also be eliminated because it is a vegetable. The remaining options are the correct options.
References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 799-800; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. p. 610.

28. *Answer:* 2
Rationale: In iron-deficiency anemia, iron stores are depleted, resulting in a decreased supply of iron for the manufacture of hemoglobin in red blood cells. An oral iron supplement needs to be administered through a straw or medicine dropper placed at the back of the mouth, because the iron stains the teeth. Clients need to be instructed to brush or wipe their teeth after administration. Iron is administered between meals, because absorption is decreased if there is food in the stomach. Iron requires an acid environment to facilitate its absorption in the duodenum. Iron is not mixed with liquids, cereal, or other food items.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Eliminate options 3 and 4 first because they are **comparable or alike** and because medication would not be added to apple juice or food. Next, note the word *liquid* in the question. This will assist you in recalling that iron in liquid form stains teeth.

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. p.651; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Mosby. p.850.

29. *Answer:* 4

Rationale: In iron-deficiency anemia, iron stores are depleted, resulting in a decreased supply of iron for the manufacture of hemoglobin in red blood cells. The results of a complete blood cell count in clients with iron-deficiency anemia show decreased hemoglobin levels and microcytic and hypochromic red blood cells. The red blood cell count is decreased. The reticulocyte count is usually normal or slightly elevated.

Test-Taking Strategy: Focus on the **subject,** laboratory findings. Eliminate options 1 and 3 first, knowing that the hemoglobin and red blood cell counts would be decreased. From the remaining options, select the correct option over option 2 because of the relationship between anemia and red blood cells.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Saunders. pp. 798-799.

CHAPTER 46

Oncological and Hematological Medications

Contributors: David Petersen, MSN-Ed, RN
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS Cellular Regulation; Safety

Note: Oncological medications are prescribed to treat cancer. Hematological medications are prescribed to treat conditions and diseases related to the blood and blood-forming organs. Blood components are affected when the client receives oncological medications. Hematological medications specific to treating the effects of oncological medications on the body are included in this chapter. Research is continuously being conducted to identify new treatments for cancer. For updates, refer to the American Cancer Society at https://www.cancer.org/

I. Antineoplastic Medications

A. Description

1. Antineoplastic medications, also known as chemotherapy, kill or inhibit the reproduction of neoplastic cells.
2. Antineoplastic medications are used for a cure, to increase survival time, or to decrease life-threatening complications.
3. The effect of antineoplastic medications may not be limited to neoplastic cells; normal cells may also be affected by the medication.
4. Cell cycle phase–specific medications affect cells only during a certain phase of the reproductive cycle (Fig. 46.1).
5. Cell cycle phase–nonspecific medications affect cells in any phase of the reproductive cycle (see Fig. 46.1).
6. Usually, several medications are used in combination to increase the therapeutic response.
7. Antineoplastic medications may be combined with other treatments, such as surgery and radiation.
8. Although the intravenous (IV) route is most common for administration, antineoplastic medication may be given by the oral, intra-arterial, isolated limb perfusion, or intracavitary route; dosing is usually based on the client's body surface area (BSA) and type of cancer.
9. Antineoplastic or chemotherapy dosing is usually based on total BSA, which requires a current accurate height and weight for BSA calculation (before each medication administration) to ensure that the client receives optimal doses of chemotherapy medications.

⚠ Side and adverse effects from chemotherapy result from the effects of the antineoplastic medication on normal cells.

B. Side and adverse effects

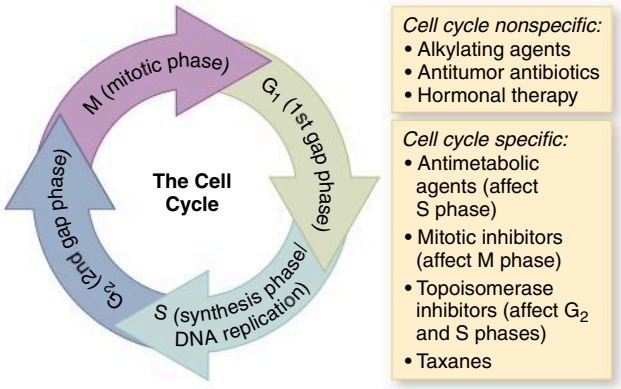
1. Anorexia, nausea, and vomiting
2. Mucositis
3. Alopecia
4. Diarrhea
5. Anemia
6. Low white blood cell count (neutropenia)
7. Thrombocytopenia
8. Infertility, sexual alterations
9. Neuropathy

⚠ Antineoplastic medications cause the rapid destruction of cells, resulting in the release of uric acid. Allopurinol may be prescribed to lower the serum uric acid level, particularly in leukemia and lymphoma cancers.

C. General interventions

1. Physiological integrity
   - **a.** Monitor complete blood cell count, white blood cell count, platelet count, uric acid level, and electrolytes.
   - **b.** Initiate bleeding precautions if thrombocytopenia occurs.
   - **c.** When the platelet count is less than 50,000 mm^3 (50×10^9/L), minor trauma can lead to episodes of prolonged bleeding; when less than 20,000 mm^3 (20×10^9/L), spontaneous and uncontrollable bleeding can occur;

Telegram & Insta: NCLEX_RN_Edu



M (mitotic phase)
G1 (1st gap phase)
S (synthesis phase/ DNA replication)
G2 (2nd gap phase)
The Cell Cycle
Cell cycle nonspecific:
• Alkylating agents
• Antitumor antibiotics
• Hormonal therapy
Cell cycle specific:
• Antimetabolic agents (affect S phase)
• Mitotic inhibitors (affect M phase)
• Topoisomerase inhibitors (affect G2 and S phases)
• Taxanes

FIG. 46.1 The cell cycle. *G1*, the cell is preparing for division; *S* (synthesis phase/DNA replication), the cell doubles its DNA content through DNA synthesis; *G2*, the cell produces proteins to be used in cell division and in normal physiological function after cell division is complete; *M* (mitotic phase), the single cell splits apart into two cells.

withhold the medication if the platelet count drops (according to agency policy), and notify the primary health care provider (PHCP). Bleeding precautions are initiated.

d. Monitor for petechiae, ecchymoses, bleeding of the gums, and nosebleeds, because the decreased platelet count can precipitate bleeding tendencies.

e. Avoid intramuscular injections and venipunctures as much as possible to prevent bleeding.

f. Withhold the medication and initiate neutropenic precautions if the segmented neutrophil count decreases below 18% conventional units (0.18 SI units) or the absolute neutrophil count (ANC) is below 1000; notify the oncologist. (See Clinical Judgment: Take Action Box.)

g. Monitor for fever, sore throat, unusual bleeding, and signs and symptoms of infection.

h. Inform the client that loss of appetite also may be the result of taste changes or a bitter taste in the mouth from the medications.

i. Monitor for nausea and vomiting, and provide a high-calorie diet with protein supplements.

j. Administer antiemetics several hours before chemotherapy and for 12 to 48 hours after as prescribed, because antineoplastic medications stimulate the vomiting center in the brain.

k. Encourage hydration; IV fluids are administered before and during therapy.

l. Promote a fluid intake of at least 2000 mL/day to maintain adequate renal function.

An absolute neutrophil count (ANC) measures the percentage of neutrophils in the white blood cell (WBC) count. To calculate the ANC multiply the number of WBCs by the percentage of total neutrophils. For example, for a WBC count of 6000 mm^3, if neutrophils constitute 40% of the WBCs, the ANC will be 6000 × 0.40 = 2400. A normal ANC is over 1000.

2. Safe and effective care environment
   - **a.** Prepare IV chemotherapy in an air-vented space (biological safety cabinet).
   - **b.** Wear appropriate personal protective equipment (PPE), including gloves, gown, eye protectors, and mask as indicated, to reduce exposure whenever there is a risk of hazardous medications being released into the environment.
   - **c.** Nurses who are pregnant should avoid chemotherapy preparation or the administration of chemotherapy.
   - **d.** Discard IV equipment in designated (biohazard) containers.
   - **e.** Administer antineoplastic medication precisely as prescribed to maximize antineoplastic effects while allowing normal cells to recover.
   - **f.** Monitor for **phlebitis** with IV administration, because these medications may irritate the veins.
   - **g.** Vesicants should be administered through a central line when possible; if a peripheral line is used, blood return should be checked prior to administration.
   - **h.** As prescribed, reduce IV site pain by altering IV rates or warming the injection site to distend the vein and increase blood flow.
   - **i.** Monitor for extravasation (leakage of medication into surrounding skin and subcutaneous tissue, which causes tissue necrosis), and notify the PHCP if this occurs; heat or ice is applied, depending on the medication, and an antidote may be injected into the site.
3. Psychosocial integrity
   - **a.** Instruct the client about the possibility of hair loss and that varying degrees of hair loss may occur after the first or second treatment.
   - **b.** Discuss the purchase of a wig before treatment starts, and consider cutting the hair short.

CLINICAL JUDGMENT: TAKE ACTION

The nurse in the chemotherapy department of an oncology center notes that a client who needs to receive a scheduled antineoplastic medication has an absolute neutrophil count (ANC) of 900. The nurse recognizes this value as low, indicating moderate neutropenia. Knowing that the client with neutropenia is at risk for infection, the nurse would contact the oncologist for further prescriptions before initiating the chemotherapy infusion. The chemotherapy infusion will probably be withheld and rescheduled after another follow-up ANC evaluation. The client needs to be instructed on neutropenic precautions to protect self from infection.

Telegram & Insta: NCLEX_RN_Edu

c. Inform the client that new hair growth will occur several months after the final treatment.
d. Instruct the client about the need for contraception, because these medications have teratogenic effects.
e. Discuss the potential effect of infertility, which may be irreversible.
f. Encourage pretreatment counseling, and encourage sperm banking or preservation of eggs if the client is still of childbearing age.

4. Health promotion and maintenance
a. Instruct the client, if diarrhea is a problem, to avoid spicy foods, high-fiber foods, and foods that are hot in temperature, which increase peristalsis.
b. Instruct the client to inspect the oral mucosa frequently for erythema and ulcers, rinse the mouth after meals, and practice good oral hygiene.
c. Instruct the client to use mouth rinses as prescribed for mouth sores if necessary.
d. Instruct the client in the use of antifungal agents for mouth sores, if prescribed, for the development of a fungal infection.
e. Instruct the client to avoid crowds and persons with infections and to report signs of infection, such as a low-grade fever, chills, or sore throat.
f. Instruct individuals with colds or infections to wear a mask when visiting or to avoid visiting the client.
g. Instruct the client to use a soft toothbrush and electric razor to minimize the risk of bleeding.
h. Instruct the client to avoid aspirin-containing products to minimize the risk of bleeding.
i. Instruct the client to consult the PHCP before receiving vaccinations (live vaccines should not be administered).

The nurse needs to ensure self-safety when administering antineoplastic agents; these medications have an increased risk of leukemia, adverse reproductive outcomes, and chromosomal damage. Measures nurses can take include wearing adequate personal protective equipment when administering these medications and following facility protocol. For additional information, see https://www.cdc.gov/niosh/topics/healthcarehsps/antineoadminpredic.html.

D. Anaphylactic reactions
1. Description:
a. A severe and potentially life-threatening allergic reaction; this can occur in a client receiving an antineoplastic medication.
b. The reaction can occur within seconds or minutes of exposure to an allergen.

2. Precautions
a. Obtain an allergy history.
b. Administer a test dose when prescribed by the PHCP.
c. Stay with the client during the administration of medication.
d. Monitor vital signs.
e. Have emergency equipment and medications readily available.
f. Initiate IV access for the administration of emergency medications if needed.

3. Signs of an anaphylactic reaction
a. Dyspnea
b. Chest tightness or pain
c. Pruritus or urticaria
d. Tachycardia
e. Dizziness
f. Anxiety or agitation
g. Flushed appearance
h. Hypotension
i. Decreased sensorium
j. Cyanosis

4. Interventions for an anaphylactic reaction (see Clinical Judgment: Take Action Box)

CLINICAL JUDGMENT: TAKE ACTION

A 35-year-old client with ovarian cancer is receiving the first scheduled chemotherapy treatment with paclitaxel at the cancer center. Thirty minutes after the infusion is started the client complains of severe shortness of breath, dizziness and a feeling of passing out, chest pain, and feeling itchy. The nurse recognizes these symptoms as an acute allergic response to the paclitaxel and immediately takes the following actions.

- Stops the medication
- Contacts the Rapid Response Team and the oncologist
- Administers oxygen
- Raises the client's feet and legs, if not contraindicated
- Monitors respiratory status and vital signs
- Maintains the intravenous (IV) access with normal saline
- Prepares for intubation if severe respiratory distress develops
- Administers prescribed emergency medications, such as epinephrine
- Documents the event, actions taken, and the client's response

II. Alkylating Medications (Box 46.1)

A. Description
1. Break the DNA helix, thereby interfering with DNA replication

Telegram & Insta: NCLEX_RN_Edu

BOX 46.1 Alkylating Medications

Nitrogen Mustards
- Bendamustine
- Chlorambucil
- Cyclophosphamide
- Ifosfamide
- Estramustine
- Mechlorethamine
- Melphalan

Nitrosoureas
- Carmustine
- Lomustine
- Streptozocin

Alkylating-Like Medications
- Altretamine
- Busulfan
- Carboplatin
- Cisplatin
- Dacarbazine
- Oxaliplatin
- Temozolomide
- Thiotepa
- Trabectedin

2. Cell cycle phase–nonspecific medications

B. Side and adverse effects
1. Anorexia, nausea, and vomiting may occur.
2. Stomatitis may occur.
3. Rash may occur.
4. Client may feel IV site pain during IV administration.
5. Busulfan may cause hyperuricemia.
6. Chlorambucil and mechlorethamine may cause gonadal suppression and hyperuricemia.
7. Cisplatin, a platinum compound, may cause ototoxicity, tinnitus, hypokalemia, hypocalcemia, hypomagnesemia, and nephrotoxicity.

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).
1. Cyclophosphamide may cause alopecia, gonadal suppression, hemorrhagic cystitis, and hematuria.
2. Ifosfamide may cause hemorrhagic cystitis and neurotoxicity.
3. Assess results of pulmonary function tests.
4. Assess results of chest radiography and renal and liver function studies.
5. When administering cisplatin, assess the client for dizziness, tinnitus, hearing loss, incoordination, and numbness or tingling of extremities.
6. Mesna may be administered with ifosfamide to reduce the potential for ifosfamide-induced cystitis.
7. Instruct the client that cyclophosphamide, when prescribed orally, is administered without food.
8. Instruct the client to follow a diet low in purines to alkalinize the urine and lower uric acid blood levels.
9. Instruct the client about how to avoid infection.
10. Instruct the client to report signs of infection or bleeding.
11. Instruct the client about good oral hygiene and the use of a soft toothbrush.

⚠ Cyclophosphamide and ifosfamide are medications that can cause hemorrhagic cystitis. Encourage the client to drink increased fluids (2 to 3 L/day) during therapy, unless contraindicated.

III. Antitumor Antibiotic Medications (Box 46.2)

A. Description
1. Interfere with DNA and RNA synthesis
2. Cell cycle phase–nonspecific medications

B. Side and adverse effects
1. Nausea and vomiting
2. Fever
3. Bone marrow depression
4. Rash
5. Alopecia
6. Stomatitis
7. Gonadal suppression
8. Hyperuricemia
9. Vesication (blistering of tissue at IV site)
10. Daunorubicin may cause heart failure and dysrhythmias.
11. Doxorubicin and idarubicin may cause cardiotoxicity, cardiomyopathy, and electrocardiographic changes (dexrazoxane, which is a cardioprotective agent, may be administered with doxorubicin to reduce cardiomyopathy).
12. Pulmonary toxicity can occur with bleomycin.

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).
1. Assess results of pulmonary function tests.
2. Monitor for electrocardiographic changes.
3. Assess lung sounds for crackles.
4. Assess for signs of heart failure, including dyspnea, crackles, peripheral edema, and weight gain.
5. Assess results of chest radiography and renal and liver function studies.
6. Assess for myocardial toxicity, dyspnea, dysrhythmias, hypotension, and weight gain when administering doxorubicin or idarubicin.
7. Monitor pulmonary status when administering bleomycin.

IV. Antimetabolite Medications (Box 46.3)

A. Description
1. Antimetabolite medications halt the synthesis of cell protein; their presence impairs cell division.
2. Antimetabolite medications are cell cycle phase–specific and affect the S phase.

B. Side and adverse effects
1. Anorexia, nausea, and vomiting
2. Diarrhea
3. Alopecia
4. Stomatitis
5. Depression of bone marrow

Telegram & Insta: NCLEX_RN_Edu

BOX 46.2 Antitumor Antibiotic Medications

- Bleomycin sulfate
- Dactinomycin
- Daunorubicin
- Doxorubicin
- Epirubicin
- Idarubicin
- Mitomycin
- Mitoxantrone
- Valrubicin

BOX 46.3 Antimetabolite Medications

- Azacitidine
- Capecitabine
- Cladribine
- Clofarabine
- Cytarabine
- Decitabine
- Floxuridine
- Fludarabine
- Fluorouracil
- Gemcitabine
- Hydroxyurea
- Mercaptopurine
- Methotrexate
- Nelarabine
- Pemetrexed
- Pentostatin
- Pralatrexate
- Thioguanine

6. Cytarabine may cause alopecia, stomatitis, hyperuricemia, and hepatotoxicity.
7. Fluorouracil may cause alopecia, stomatitis, diarrhea, phototoxicity reactions, and cerebellar dysfunction.
8. Mercaptopurine may cause hyperuricemia and hepatotoxicity.
9. Methotrexate may cause alopecia; stomatitis; hyperuricemia; photosensitivity; hepatotoxicity; and hematological, gastrointestinal, and skin toxicity.

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).

1. Monitor renal function studies.
2. Monitor for cerebellar dysfunction.
3. Assess for photosensitivity.
4. When administering fluorouracil, assess for signs of cerebellar dysfunction, such as dizziness, weakness, and ataxia, and assess for stomatitis and diarrhea, which may necessitate discontinuation of the medication.
5. When administering fluorouracil or methotrexate, instruct the client to use sunscreen and wear protective clothing to prevent photosensitivity reactions.

When administering methotrexate in large doses, prepare to administer leucovorin as prescribed to prevent toxicity. This is known as leucovorin rescue.

V. Mitotic Inhibitor Medications (*Vinca* Alkaloids) (Box 46.4)

A. Description

1. Mitotic inhibitors prevent mitosis, causing cell death.
2. Mitotic inhibitors are cell cycle phase–specific and act on the M phase.

B. Side and adverse effects

1. Leukopenia
2. Neurotoxicity with vincristine, manifested as numbness and tingling in the fingers and toes; constipation, and paralytic ileus can also occur.
3. Ptosis
4. Hoarseness
5. Motor instability
6. Anorexia, nausea, and vomiting
7. Peripheral neuropathy
8. Alopecia
9. Stomatitis
10. Hyperuricemia
11. Phlebitis at IV site. (Best practice is IV administration by piggyback via minibag and not IV push.)

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).

1. Monitor for hoarseness.
2. Assess eyes for ptosis.
3. Assess motor stability, and initiate safety precautions as necessary.
4. Monitor for neurotoxicity with vincristine, manifested as numbness and tingling in the fingers and toes.
5. Monitor for constipation and paralytic ileus.

VI. Topoisomerase Inhibitors (Box 46.5)

A. Description

1. Block an enzyme needed for DNA synthesis and cell division
2. Cell cycle phase–specific; act on the G_2 and S phases

B. Side and adverse effects

1. Leukopenia, thrombocytopenia, and anemia
2. Anorexia, nausea, and vomiting
3. Diarrhea
4. Alopecia
5. Orthostatic hypotension
6. Hypersensitivity reaction

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).

VII. Hormonal Medications and Enzymes (Box 46.6)

A. Description

1. Suppress the immune system and block normal hormones in hormone-sensitive tumors

Telegram & Insta: NCLEX_RN_Edu

BOX 46.4 Mitotic Inhibitors

***Vinca* Alkaloids**
- Vinblastine sulfate
- Vincristine sulfate
- Vinorelbine

Taxanes
- Cabazitaxel
- Docetaxel
- Paclitaxel

BOX 46.5 Topoisomerase Inhibitors

- Etoposide
- Irinotecan
- Teniposide
- Topotecan

BOX 46.6 Hormonal Medications and Enzymes

Estrogens
- Estramustine
- Ethinyl estradiol

Antiestrogens
- Anastrozole
- Exemestane
- Fulvestrant
- Letrozole
- Raloxifene
- Tamoxifen citrate
- Toremifene

Antiandrogens
- Apalutamide
- Bicalutamide
- Darolutamide
- Enzalutamide
- Flutamide
- Goserelin acetate
- Histrelin
- Nilutamide
- Triptorelin

Progestins
- Medroxyprogesterone
- Megestrol acetate

Other Hormonal Antagonists and Enzymes
- Asparaginase
- Leuprolide acetate
- Mitotane

BOX 46.7 Immunomodulators and Targeted Therapies

Interleukins and Interferons
- Aldesleukin
- Interferon α-2a
- Interferon α-2b
- Interferon α-n3
- Recombinant interferon α-2a
- Recombinant interferon α-2b

Common Monoclonal Antibodies
- Bevacizumab
- Cetuximab
- Ibritumomab
- Infliximab
- Panitumumab
- Pembrolizumab
- Rituximab
- Trastuzumab

Small Molecule Inhibitors
- Bortezomib
- Bosutinib
- Dasatinib
- Erlotinib
- Gefitinib
- Imatinib
- Lapatinib
- Nilotinib
- Ponatinib
- Sorafenib
- Sunitinib
- Temsirolimus

2. Change the hormonal balance and slow the growth rates of certain tumors

B. Side and adverse effects
1. Anorexia, nausea, and vomiting
2. Leukopenia
3. Impaired pancreatic function with asparaginase
4. Sex characteristic alterations
   a. Masculinizing effect: Chest and facial hair, menses stops
   b. Feminine manifestations: Gynecomastia
5. Breast swelling
6. Hot flashes
7. Weight gain
8. Hemorrhagic cystitis, hypouricemia, and hypercholesterolemia, with mitotane
9. Hypertension
10. Thromboembolic disorders
11. Edema
12. Electrolyte imbalances
13. Tamoxifen citrate
    a. May cause edema, hypercalcemia, and elevated cholesterol and triglyceride levels
    b. Risk of venous thromboembolism is increased in older clients.
    c. Decreases the effects of estrogen

C. Interventions: Refer to Section I, C (Antineoplastic Medications—General Interventions).
1. Assess medications that the client is taking currently.
2. Monitor serum calcium levels with androgens.
3. Monitor for signs of alterations in sexual characteristics.
4. Monitor pancreatic function with asparaginase.
5. Monitor uric acid and cholesterol levels.
6. Monitor for signs of hemorrhagic cystitis.

VIII. Immunomodulator (Immunotherapy) Agents: Biological Response Modifiers (Box 46.7)

A. Description
1. Immunomodulators stimulate the immune system to recognize cancer cells and take action to eliminate or destroy them.
2. Interleukins help various immune system cells to recognize and destroy abnormal body cells.
3. Interferons slow tumor cell division, stimulate proliferation, and cause cancer cells to differentiate into nonproliferative forms.

B. Colony-stimulating factors induce more rapid bone marrow recovery after suppression by chemotherapy (Box 46.8).

Telegram & Insta: NCLEX_RN_Edu

BOX 46.8 Colony-Stimulating Factors

Granulocyte Macrophage Colony–Stimulating Factor
- Sargramostim

Granulocyte Colony–Stimulating Factor
- Filgrastim
- Pegfilgrastim

Erythropoietin
- Epoetin α
- Darbepoetin α

IX. Targeted Therapy

A. Description (see Box 46.7)
  1. Medications used as targeted therapies are monoclonal antibodies and small molecule inhibitors that target a cellular element of the cancer cell or antisense medications that work at the gene level.
  2. Examples of monoclonal antibodies are rituximab, trastuzumab, alemtuzumab, bevacizumab, and cetuximab.

B. Adverse effects: Allergic reactions (monoclonal antibodies)

X. Other Antineoplastic Medications

A. Altretamine: Cytotoxic agent used to treat ovarian cancer

B. Denileukin diftitox: Recombinant DNA–derived medication used to treat cutaneous T-cell lymphoma

C. Pegaspargase: Used in combination chemotherapies for acute lymphoblastic leukemia in clients unable to take asparaginase

D. Bexarotene: Used to treat advanced-stage cutaneous T-cell lymphoma

XI. Medications to Treat Anemia (see Chapter 45 for more information)

A. Iron-deficiency anemia: Iron administration

B. Vitamin B_{12}–deficiency anemia: Vitamin B_{12} administration

C. Folate-deficiency anemia: Folate administration

D. Acute blood loss anemia: Blood transfusion, packed red blood cells, platelets, or fresh frozen plasma, depending on cause

E. Anemia of chronic disease: Iron administration, erythropoietic growth factors, leukopoietic growth factors, and thrombopoietic growth factors (see Chapter 56 for more information)

PRACTICE QUESTIONS

1. Chemotherapy dosage is frequently based on total body surface area (BSA), so it is important for the nurse to perform which assessment before administering chemotherapy?
  1. Measure the client's abdominal girth.
  2. Calculate the client's body mass index.
  3. Measure the client's current weight and height.
  4. Ask the client to share current weight and height.

2. A client with squamous cell carcinoma of the larynx is receiving bleomycin intravenously. The nurse caring for the client anticipates that which diagnostic study will be prescribed?
  1. Echocardiography
  2. Electrocardiography
  3. Cervical radiography
  4. Pulmonary function studies

3. A client with acute myelocytic leukemia is being treated with busulfan. Which laboratory value would the nurse specifically monitor during treatment with this medication?
  1. Clotting time
  2. Uric acid level
  3. Potassium level
  4. Blood glucose level

4. A client with small cell lung cancer is being treated with etoposide. The nurse monitors the client during administration, knowing that which adverse effect is specifically associated with this medication?
  1. Alopecia
  2. Chest pain
  3. Pulmonary fibrosis
  4. Orthostatic hypotension

5. A clinic nurse prepares a teaching plan for a client receiving an antineoplastic medication. When implementing the plan, the nurse would make which statement to the client?
  1. "You can take aspirin as needed for headache."
  2. "You can drink beverages containing alcohol in moderate amounts each evening."
  3. "You need to consult with the primary health care provider (PHCP) before receiving immunizations."
  4. "It is fine to receive a flu vaccine at the local health fair without PHCP approval because the flu is so contagious."

Telegram & Insta: NCLEX_RN_Edu

6. A client with ovarian cancer is being treated with vincristine. The nurse monitors the client, knowing that which manifestation indicates an adverse effect specific to this medication?
   1. Diarrhea
   2. Hair loss
   3. Chest pain
   4. Peripheral neuropathy

7. The nurse is reviewing the history and physical examination of a client who will be receiving asparaginase, an antineoplastic agent. The nurse contacts the primary health care provider before administering the medication if which disorder is documented in the client's history?
   1. Pancreatitis
   2. Diabetes mellitus
   3. Myocardial infarction
   4. Chronic obstructive pulmonary disease

8. Tamoxifen citrate is prescribed for a client with metastatic breast carcinoma. The client asks the nurse if a family member with bladder cancer can also take this medication. The nurse **most appropriately** responds by making which statement?
   1. "This medication can be used only to treat breast cancer."
   2. "Yes, your family member can take this medication for bladder cancer as well."
   3. "This medication can be taken to prevent and treat clients with breast cancer."
   4. "This medication can be taken by anyone with cancer as long as their health care provider approves it."

9. A client with metastatic breast cancer is receiving tamoxifen. The nurse specifically monitors which laboratory value while the client is taking this medication?
   1. Glucose level
   2. Calcium level
   3. Potassium level
   4. Prothrombin time

10. Megestrol acetate, an antineoplastic medication, is prescribed for a client with metastatic endometrial carcinoma. The nurse reviews the client's history and would contact the primary health care provider if which diagnosis is documented in the client's history?
    1. Gout
    2. Asthma
    3. Myocardial infarction
    4. Venous thromboembolism

11. The nurse is monitoring the intravenous (IV) infusion of an antineoplastic medication. During the infusion, the client complains of pain at the insertion site. On inspection of the site, the nurse notes redness and swelling and that the infusion of the medication has slowed in rate. The nurse suspects extravasation and would take which actions? **Select all that apply.**
    - ❑ 1. Stop the infusion.
    - ❑ 2. Prepare to apply ice or heat to the site.
    - ❑ 3. Restart the IV at a distal part of the same vein.
    - ❑ 4. Notify the primary health care provider (PHCP).
    - ❑ 5. Prepare to administer a prescribed antidote into the site.
    - ❑ 6. Increase the flow rate of the solution to flush the skin and subcutaneous tissue.

12. The nurse is analyzing the laboratory results of a client with leukemia who has received a regimen of chemotherapy. Which laboratory value would the nurse specifically note as a result of the massive cell destruction that occurred from the chemotherapy?
    1. Anemia
    2. Decreased platelets
    3. Increased uric acid level
    4. Decreased leukocyte count

13. The nurse is providing medication instructions to a client with breast cancer who is receiving cyclophosphamide. The nurse would tell the client to take which action?
    1. Take the medication with food.
    2. Increase fluid intake to 2000 to 3000 mL daily.
    3. Decrease sodium intake while taking the medication.
    4. Increase potassium intake while taking the medication.

14. A client with non-Hodgkin's lymphoma is receiving daunorubicin. Which finding would indicate to the nurse that the client is experiencing an adverse effect related to the medication?
    1. Fever
    2. Sores in the mouth and throat
    3. Complaints of nausea and vomiting
    4. Crackles on auscultation of the lungs

15. The nurse is monitoring the laboratory results of a client receiving an antineoplastic medication by the intravenous route. The nurse plans to initiate bleeding precautions if which laboratory result is noted?
    1. A clotting time of 10 minutes
    2. An ammonia level of 10 mcg/dL (6 mcmol/L)
    3. A platelet count of 50,000 mm^3 (50×10^9/L)
    4. A white blood cell count of 5000 mm^3 (5.0×10^9/L)

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 3

Rationale: To ensure that the client receives optimal doses of chemotherapy, dosing is usually based on the total BSA, which requires a current accurate height and weight for BSA calculation (before each medication administration). Asking the client about current height and weight may lead to inaccuracies in determining a true BSA and dosage. Calculating body mass index and measuring abdominal girth will not provide the data needed.

Test-Taking Strategy: Recall the basis for dosing chemotherapy. Recalling that a current accurate height and weight need to be obtained for BSA calculation and chemotherapy dosing will direct you to the correct option. Eliminate option 4 because it is an unreliable way of obtaining the information. Next, eliminate options 1 and 2 because they are comparable or alike and do not relate to chemotherapy dosing.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1200-1201.

2. *Answer:* 4

Rationale: Bleomycin is an antineoplastic medication that can cause interstitial pneumonitis, which can progress to pulmonary fibrosis. Pulmonary function studies along with hematological, hepatic, and renal function tests need to be monitored. The nurse needs to monitor lung sounds for dyspnea and crackles, which indicate pulmonary toxicity. The medication needs to be discontinued immediately if pulmonary toxicity occurs. Options 1, 2, and 3 are unrelated to the specific use of this medication.

Test-Taking Strategy: Eliminate options 1 and 2 first because they are cardiac related and are therefore comparable or alike. From the remaining options, use the ABCs—airway, breathing, and circulation—to direct you to the correct option.

Reference: Gahart, B., Nazareno, A., & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. pp. 186, 188.

3. *Answer:* 2

Rationale: Busulfan can cause an increase in the uric acid level. Hyperuricemia can produce uric acid nephropathy, renal stones, and acute kidney injury. Options 1, 3, and 4 are not specifically related to this medication.

Test-Taking Strategy: Focus on the subject, a specific laboratory value. It is necessary to know the adverse effects associated with this medication. Recalling that busulfan increases the uric acid level will direct you to the correct option.

Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 202-203.

4. *Answer:* 4

Rationale: An adverse effect specific to etoposide is orthostatic hypotension. Etoposide needs to be administered slowly over 30 to 60 minutes to avoid hypotension. The client's blood pressure is monitored during the infusion. Hair loss occurs with nearly all antineoplastic medications. Chest pain and pulmonary fibrosis are unrelated to this medication.

Test-Taking Strategy: Eliminate option 1 first, because this adverse effect is associated with many of the antineoplastic agents. Eliminate options 2 and 3 next because they are comparable or alike and are unrelated to etoposide. Note that the question asks for the adverse effect *specific* to this medication. Correlate hypotension with etoposide.

Reference: Gahart, B., Nazareno, A., & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. pp. 590, 592.

5. *Answer:* 3

Rationale: Because antineoplastic medications lower the resistance of the body, clients must be informed not to receive immunizations without the PHCP's approval. Clients also need to avoid contact with individuals who have recently received a live virus vaccine. Clients need to avoid aspirin and aspirin-containing products to minimize the risk of bleeding, and they need to avoid alcohol to minimize the risk of toxicity and side/adverse effects.

Test-Taking Strategy: Focus on the subject, client teaching about an antineoplastic medication, and think about the side/adverse effects of antineoplastic medications. Recalling that antineoplastic medications lower the resistance of the body will direct you to the correct option.

References: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 771; American Cancer Society: Vaccinations and Flu Shots for People with Cancer at https://www.cancer.org/treatment/treatments-and-side-effects/physical-side-effects/low-blood-counts/infections/vaccination-during-cancer-treatment.html

6. *Answer:* 4

Rationale: An adverse effect specific to vincristine is peripheral neuropathy, which occurs in almost every client. Peripheral neuropathy can be manifested as numbness and tingling in the fingers and toes. Depression of the Achilles tendon reflex may be the first clinical sign indicating peripheral neuropathy. Constipation rather than diarrhea is most likely to occur with this medication, although diarrhea may occur occasionally. Hair loss occurs with nearly all antineoplastic medications. Chest pain is unrelated to this medication.

Test-Taking Strategy: Eliminate options 1 and 2 first because they are comparable or alike and are side/adverse effects associated with many of the antineoplastic agents. Note that the question asks for the adverse effect *specific* to this medication. Correlate peripheral neuropathy with vincristine.

Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. p. 1230.

7. *Answer:* 1

Rationale: Asparaginase is contraindicated if hypersensitivity exists, in pancreatitis, or if the client has a history of pancreatitis. The medication impairs pancreatic function, and pancreatic function tests need to be performed before therapy begins and when a week or more has elapsed between dose administrations. The client needs to be monitored for signs of pancreatitis, which include nausea, vomiting, and abdominal pain. The conditions noted in options 2, 3, and 4 are not contraindicated with this medication.

Test-Taking Strategy: Focus on the subject, a contraindication of asparaginase. It is necessary to know the contraindications associated with this medication. Recalling that this

Telegram & Insta: NCLEX_RN_Edu

medication affects pancreatic function will direct you to the correct option.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. p. 1242.

8. *Answer:* 3
Rationale: Tamoxifen is an antineoplastic medication that competes with estradiol for binding to estrogen in tissues containing high concentrations of receptors. Tamoxifen is used to treat metastatic breast carcinoma. Tamoxifen is also effective in delaying the recurrence of cancer following mastectomy and for preventing breast cancer in those who are at high risk.
Test-Taking Strategy: Note the **strategic words,** *most appropriately.* Recalling that this medication is used for breast cancer will assist you in eliminating options 2 and 4. Note the **closed-ended word** "only" in option 1 to assist you in eliminating this option. Also, recall that this medication is used for both prevention and treatment of breast cancer.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. pp. 1246, 1248.

9. *Answer:* 2
Rationale: Tamoxifen may increase calcium, cholesterol, and triglyceride levels. Before the initiation of therapy, a complete blood count, platelet count, and serum calcium level should be assessed. These blood levels, along with cholesterol and triglyceride levels, need to be monitored periodically during therapy. The nurse would assess for hypercalcemia while the client is taking this medication. Signs of hypercalcemia include increased urine volume, excessive thirst, nausea, vomiting, constipation, hypotonicity of muscles, and deep bone and flank pain.
Test-Taking Strategy: Focus on the **subject,** the laboratory value to monitor for tamoxifen. Think about the action of this medication. Recalling that this medication causes hypercalcemia will direct you to the correct option.
Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. p. 1117.

10. *Answer:* 4
Rationale: Megestrol acetate suppresses the release of luteinizing hormone from the anterior pituitary by inhibiting pituitary function and regressing tumor size. Megestrol is used with caution if the client has a history of venous thromboembolism. Options 1, 2, and 3 are not contraindications for this medication.
Test-Taking Strategy: Focus on the **subject,** a contraindication to megestrol acetate. It is necessary to know the adverse effects associated with this medication. Recalling that megestrol acetate is a hormonal antagonist enzyme and that an adverse effect is thrombotic disorders will direct you to the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 800-801.

11. *Answer:* 1, 2, 4, 5
Rationale: Redness and swelling and a slowed infusion indicate signs of extravasation. If the nurse suspects extravasation during the IV administration of an antineoplastic medication, the infusion is stopped and the PHCP is notified. Ice or heat may be prescribed for application to the site, and an antidote may be prescribed to be administered into the site. Increasing the flow rate can increase damage to the tissues. Restarting an IV in the same vein can increase damage to the site and vein.
Test-Taking Strategy: Focus on the assessment signs in the question and the words *suspects extravasation*. Visualize the situation to identify the nursing actions. Think about the actions that will cause further damage. Note that options 3 and 6 are **comparable or alike** and can cause further damage.
Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 1005-1006.

12. *Answer:* 3
Rationale: Hyperuricemia is especially common following treatment for leukemias and lymphomas, because chemotherapy results in massive cell kill. Although options 1, 2, and 4 also may be noted, an increased uric acid level is related specifically to cell destruction.
Test-Taking Strategy: Focus on the **subject,** the laboratory value that reflects massive cell destruction. Remember that uric acid is released when cells are destroyed. This will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 249.

13. *Answer:* 2
Rationale: Hemorrhagic cystitis is an adverse effect that can occur with the use of cyclophosphamide. The client needs to be instructed to drink copious amounts of fluid during the administration of this medication. Clients also need to monitor urine output for hematuria. The medication needs to be taken on an empty stomach unless gastrointestinal upset occurs. Hyperkalemia can result from the use of the medication; therefore, the client would not be told to increase potassium intake. The client would not be instructed to alter sodium intake.
Test-Taking Strategy: Focus on the **subject,** client teaching about cyclophosphamide. Recalling that cyclophosphamide can cause hemorrhagic cystitis will direct you to the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 332.

14. *Answer:* 4
Rationale: Cardiotoxicity noted by abnormal electrocardiographic findings or cardiomyopathy manifested as heart failure (lung crackles) is an adverse effect of daunorubicin. Bone marrow depression is also an adverse effect. Fever is a frequent side effect, and sores in the mouth and throat can occur occasionally. Nausea and vomiting are frequent side effects associated with the medication, generally beginning a few hours after administration and lasting 24 to 48 hours. Options 1, 2, and 3 are not adverse effects.
Test-Taking Strategy: Keep in mind that the question is asking about an adverse effect. Use of the **ABCs—airway, breathing, and circulation—**will direct you to the correct option.

Telegram & Insta: NCLEX_RN_Edu

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. pp. 1237-1238; Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. pp. 324-325.

15. *Answer:* 3

Rationale: Bleeding precautions need to be initiated when the platelet count decreases. The normal platelet count is 150,000 to 450,000 mm^3 (150 to 400 × 10^9/L). When the platelet count decreases, the client is at risk for bleeding. The normal white blood cell count is 5000 to 10,000 mm^3 (5.0 to 10.0 × 10^9/L). When the white blood cell count drops, neutropenic precautions need to be implemented. The normal clotting time is 8 to 15 minutes. The normal ammonia value is 10 to 80 mcg/dL (6 to 47 mcmol/L).

Test-Taking Strategy: Use knowledge regarding normal laboratory values. Options 1, 2, and 4 are **comparable or alike** and identify normal laboratory values. Remember to correlate a low platelet count with the need for bleeding precautions and a low white blood cell count with the need for neutropenic precautions.

UNIT IX

Endocrine Problems of the Adult Client

Pyramid to Success

The endocrine system is made up of organs or glands that secrete hormones and release them directly into the circulation. The endocrine system can be understood easily if you remember that basically one of two situations can occur—hypersecretion or hyposecretion of hormones from the organ or gland. When an excess of the hormone occurs, treatment is aimed at blocking the hormone release through medication or surgery. When a deficit of the hormone exists, treatment is aimed at replacement therapy. Pyramid Points focus on diabetes mellitus, including its prevention, the prevention and treatment of complications, insulin therapy, hypoglycemic and hyperglycemic reactions, and acute and chronic complications of diabetes; Addison's disease and addisonian crisis; Cushing's disease or Cushing's syndrome; thyroid problems and thyroid storm; and care of the client after thyroidectomy or adrenalectomy.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Acting as a client advocate
Collaborating with the interprofessional team and appropriate care providers regarding treatment
Ensuring that informed consent for treatments and procedures has been obtained
Handling hazardous and infectious materials
Maintaining confidentiality related to the health problem
Preventing accidents and client injury
Prioritizing hypotheses related to the client's health problem
Using medical and surgical asepsis to prevent infection

Health Promotion and Maintenance

Generating solutions for prevention and teaching about self-care measures
Identifying lifestyle choices related to the prevention of and treatment for a health problem
Performing physical assessment of the endocrine system
Preventing health problems
Providing health screening
Recognizing cues that place a client at risk for an endocrine disorder

Psychosocial Integrity

Discussing expected and unexpected body image changes
Discussing grief and loss issues related to complications of the health problem
Discussing situational role changes related to the health problem
Identifying coping mechanisms
Monitoring for sensory and perceptual alterations as a result of the health problem
Using support systems

Physiological Integrity

Evaluating outcomes of care and the effects of pharmacological therapy
Monitoring for alterations in body systems as a result of the health problem
Monitoring for complications from surgical procedures and health alterations
Monitoring for complications of diagnostic tests, treatments, and procedures
Monitoring for fluid and electrolyte imbalances
Monitoring laboratory values and trends
Preparing the client for diagnostic tests
Providing nonpharmacological comfort interventions
Providing nutrition and oral hydration measures
Taking action and providing emergency care if a complication arises

CHAPTER 47

Endocrine Problems

Contributor: David Petersen, MSN-Ed, RN

PRIORITY CONCEPTS Glucose Regulation; Hormonal Regulation

I. Anatomy and Physiology of Endocrine Glands (Box 47.1)

A. Functions
1. Maintenance and regulation of vital functions
2. Response to stress and injury
3. Growth and development
4. Energy metabolism
5. Reproduction
6. Fluid, electrolyte, and acid-base balance

B. Risk factors for endocrine problems (Box 47.2)

C. Hypothalamus (Box 47.3)
1. Portion of the diencephalon of the brain, forming the floor and part of the lateral wall of the third ventricle
2. Activates, controls, and integrates the peripheral autonomic nervous system, endocrine processes, and many somatic functions, such as body temperature, sleep, and appetite

D. Pituitary gland (Box 47.4; Fig. 47.1)
1. The master gland; located at the base of the brain
2. Influenced by the hypothalamus; directly affects the function of the other endocrine glands
3. Promotes growth of body tissue, influences water absorption by the kidney, and controls sexual development and function

BOX 47.1 Endocrine Glands

- Adrenal
- Hypothalamus
- Ovaries
- Pancreas
- Parathyroid
- Pituitary
- Testes
- Thyroid

BOX 47.2 Risk Factors for Endocrine Problems

- Age
- Poor diet
- Heredity
- Congenital factors
- Trauma
- Environmental factors
- Consequence of other health problems or surgery

BOX 47.3 Hypothalamus Hormones

- Corticotropin-releasing hormone (CRH)
- Gonadotropin-releasing hormone (GnRH)
- Growth hormone–inhibiting hormone (GHIH)
- Growth hormone–releasing hormone (GHRH)
- Melanocyte-inhibiting hormone (MIH)
- Prolactin-inhibiting hormone (PIH)
- Thyrotropin-releasing hormone (TRH)

BOX 47.4 Pituitary Gland Hormones

Anterior Lobe Production
- Adrenocorticotropic hormone (ACTH)
- Follicle-stimulating hormone (FSH)
- Growth hormone (GH)
- Luteinizing hormone (LH)
- Melanocyte-stimulating hormone (MSH)
- Prolactin (PRL)
- Somatotropic growth-stimulating hormone
- Thyroid-stimulating hormone (TSH)

Posterior Lobe

These hormones are produced by the hypothalamus, stored in the posterior lobe, and secreted into the blood when needed:
- Oxytocin
- Vasopressin, antidiuretic hormone (ADH)

Telegram & Insta: NCLEX_RN_Edu

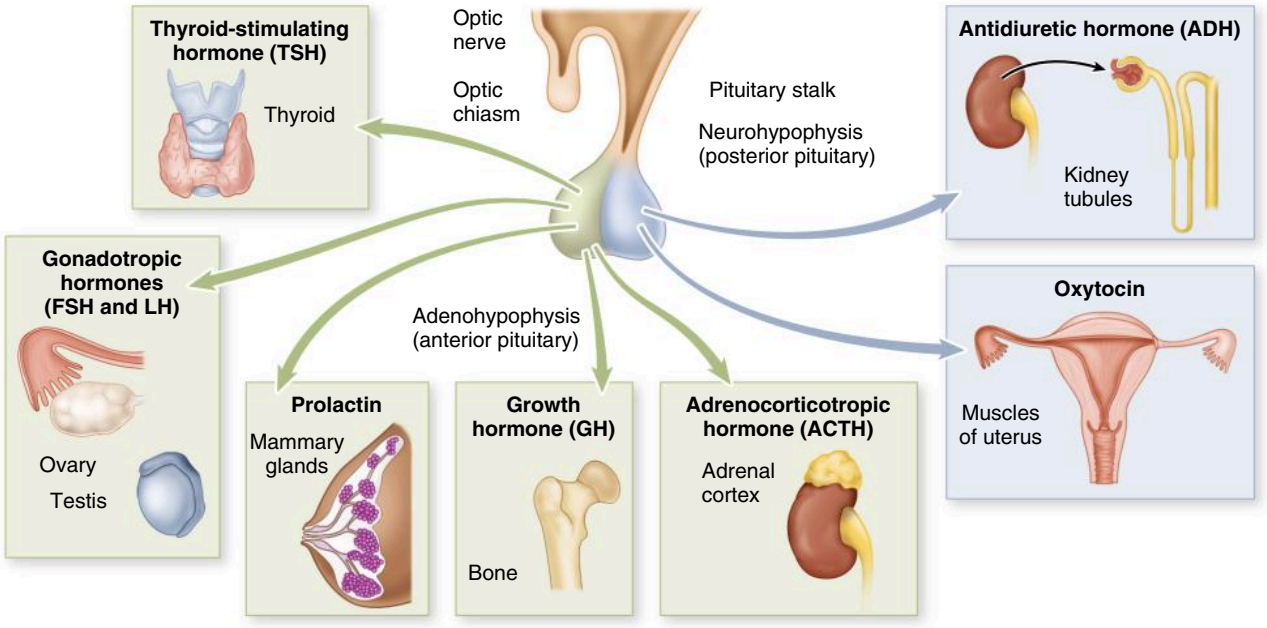

FIG. 47.1 Pituitary hormones. *FSH*, Follicle-stimulating hormone; *LH*, luteinizing hormone.

BOX 47.5 Adrenal Cortex

Glucocorticoids: Cortisol, Cortisone, Corticosterone

Responsible for glucose metabolism, protein metabolism, fluid and electrolyte balance, suppression of the inflammatory response to injury, protective immune response to invasion by infectious agents, and resistance to stress

Mineralocorticoids: Aldosterone

Regulation of electrolyte balance by promoting sodium retention and potassium excretion

E. Adrenal gland
1. One adrenal gland is on top of each kidney.
2. Regulates sodium and electrolyte balance; affects carbohydrate, fat, and protein metabolism; influences the development of sexual characteristics; and sustains the fight-or-flight response
3. Adrenal cortex
   a. The cortex is the outer shell of the adrenal gland.
   b. The cortex synthesizes glucocorticoids and mineralocorticoids and secretes small amounts of sex hormones (androgens, estrogens; Box 47.5)
4. Adrenal medulla
   a. The medulla is the inner core of the adrenal gland.
   b. The medulla works as part of the sympathetic nervous system and produces epinephrine and norepinephrine.

F. Thyroid gland
1. Located in the anterior part of the neck
2. Controls the rate of body metabolism and growth and produces thyroxine (T_4), triiodothyronine (T_3), and thyrocalcitonin

G. Parathyroid glands
1. Located on the thyroid gland
2. Control calcium and phosphorus metabolism; produce parathyroid hormone

H. Pancreas
1. Located posteriorly to the stomach
2. Influences carbohydrate metabolism, indirectly influences fat and protein metabolism, and produces insulin and glucagon

I. Ovaries and testes
1. The ovaries are located in the pelvic cavity and produce estrogen and progesterone.
2. The testes are located in the scrotum, control the development of the secondary sex characteristics, and produce testosterone.

J. Negative-feedback loop
1. Regulates hormone secretion by the hypothalamus and pituitary gland
2. Increased amounts of target gland hormones in the bloodstream decrease secretion of the same hormone and other hormones that stimulate its release.

II. Diagnostic Tests

A. Stimulation and suppression tests
1. Stimulation tests
   a. In the client with suspected underactivity of an endocrine gland, a stimulus may be provided to determine whether the gland is capable of normal hormone production.
   b. Measured amounts of selected hormones or substances are administered to stimulate the target gland to produce its hormone.
   c. Hormone levels produced by the target gland are measured.
   d. Failure of the hormone level to increase with stimulation indicates hypofunction.

Telegram & Insta: NCLEX_RN_Edu

2. Suppression tests
   a. Suppression tests are used when hormone levels are high or in the upper range of normal.
   b. Agents that normally induce a suppressed response are administered to determine whether normal negative feedback is intact.
   c. Failure of hormone production to be suppressed during standardized testing indicates hyperfunction.
3. Overnight dexamethasone suppression test
   a. Used to distinguish between **Cushing's syndrome** and **Cushing's disease**
   b. In Cushing's disease the source of excess cortisol is the pituitary gland rather than the adrenal cortex or exogenous corticosteroid administration.
   c. Dexamethasone, a potent long-acting corticosteroid given at bedtime, should suppress the morning cortisol in clients without Cushing's disease by suppressing adrenocorticotropic hormone (ACTH) production; in the client with Cushing's disease, this suppression will not occur.

B. Radioactive iodine uptake
1. This thyroid function test measures the absorption of an iodine isotope to determine how the thyroid gland is functioning.
2. A small dose of radioactive iodine is given by mouth or intravenously; the amount of radioactivity is measured in 2 to 4 hours and again at 24 hours.
3. Normal values are approximately 3% to 19% at 2 to 4 hours, and 11% to 30% in 24 hours.
4. Elevated values indicate **hyperthyroidism**, decreased iodine intake, or increased iodine excretion.
5. Decreased values indicate a low T_4 level, the use of antithyroid medications, thyroiditis, myxedema, or **hypothyroidism.**
6. The test is contraindicated in pregnancy.

C. T_3 and T_4 resin uptake test
1. Blood tests are used to diagnose thyroid disorders.
2. T_3 and T_4 regulate thyroid-stimulating hormone.
3. Normal values (normal findings vary between laboratory settings)
   a. Triiodothyronine, total T_3: 110.4 to 337.7 ng/dL (1.7 to 5.2 pmol/L)
   b. Thyroxine, total T_4: 5 to 12 mcg/dL (64 to 154 nmol/L)
   c. Thyroxine, free (FT_4): 0.8 to 2.8 ng/dL (10 to 36 pmol/L)
4. The T_4 level is elevated in hyperthyroidism and decreased in hypothyroidism.

D. Thyroid-stimulating hormone
1. Blood test is used to differentiate the diagnosis of primary hypothyroidism.
2. Normal value is 0.5 to 5.0 mIU/L.
3. Elevated values indicate primary hypothyroidism.
4. Decreased values indicate hyperthyroidism or secondary hypothyroidism.

E. Thyroid scan
1. A thyroid scan is performed to identify nodules or growths in the thyroid gland.
2. A radioisotope of iodine or technetium is administered before scanning the thyroid gland.
3. Reassure the client that the level of radioactive medication is not dangerous to self or others.
4. Determine whether the client has received radiographic contrast agents within the past 3 months, because these may invalidate the scan.
5. Check with the primary health care provider (PHCP) regarding discontinuing medications containing iodine for 14 days before the test and the need to discontinue thyroid medication before the test.
6. Instruct the client to maintain NPO (nothing by mouth) status after midnight on the day before the test; if iodine is used, the client will fast for an additional 45 minutes after ingestion of the oral isotope and the scan will be performed in 24 hours.
7. If technetium is used, it is administered by the intravenous (IV) route 30 minutes before the scan.
8. The test is contraindicated in pregnancy.

F. Needle aspiration of thyroid tissue
1. Aspiration of thyroid tissue is done for cytological examination.
2. No client preparation is necessary; NPO status may or may not be prescribed.
3. Light pressure is applied to the aspiration site after the procedure.

G. Glycosylated hemoglobin
1. HbA1c is blood glucose bound to hemoglobin.
2. **Hemoglobin A1c** (glycosylated hemoglobin A; HbA1c) is a reflection of how well blood glucose levels have been controlled for the past 90 days.
3. **Hyperglycemia** in clients with diabetes is usually a cause of an increase in HbA1c.
4. Fasting is not required before the test.
5. Normal reference intervals: <6% (adult without diabetes)
6. HbA1c and estimated average glucose (eAG) reference intervals: Refer to Table 10.4 for these reference intervals.

! Consistently poor glycemic control in a client with diabetes mellitus is usually the cause of an increase in the HbA1c value.

H. 24-hour urine collection for vanillylmandelic acid (VMA)
1. Diagnostic tests for pheochromocytoma include a 24-hour urine collection for VMA, a product of catecholamine metabolism, metanephrine, and

Telegram & Insta: NCLEX_RN_Edu

catecholamines, all of which are elevated in the presence of pheochromocytoma.

2. The normal range of urinary catecholamines:
   a. Epinephrine: less than 20 mcg/day (less than 109 nmol/day)
   b. Norepinephrine: less than 100 mcg/day (less than 590 nmol/day)

III. Pituitary Gland Problems (Box 47.6)

A. Hypopituitarism
   1. Description: Hyposecretion of one or more of the pituitary hormones caused by tumors, trauma, encephalitis, autoimmunity, or stroke
   2. Hormones most often affected are growth hormone (GH) and gonadotropic hormones (luteinizing hormone, follicle-stimulating hormone), but thyroid-stimulating hormone (TSH), adrenocorticotropic hormone (ACTH), or antidiuretic hormone (ADH) may be involved.
   3. Assessment
      a. Mild to moderate obesity (GH, TSH)
      b. Reduced cardiac output (GH, ADH)
      c. Infertility, sexual dysfunction (gonadotropins, ACTH)
      d. Fatigue, low blood pressure (TSH, ADH, ACTH, GH)
      e. Tumors of the pituitary also may cause headaches and visual defects (the pituitary is located near the optic nerve).
   4. Interventions
      a. Client may need hormone replacement for the specific deficient hormones.
      b. Provide emotional support to the client and family.
      c. Encourage the client and family to express feelings related to disturbed body image or sexual dysfunction.
      d. Client education is needed regarding the signs and symptoms of hypofunction and hyperfunction related to insufficient or excess hormone replacement.

BOX 47.6 Pituitary Gland Problems

Anterior Pituitary

- Hyperpituitarism
- Hypopituitarism

Posterior Pituitary

These problems can be caused by damage to the posterior pituitary or hypothalamus:

- Diabetes insipidus
- Syndrome of inappropriate antidiuretic hormone secretion (SIADH)

B. Hyperpituitarism (acromegaly)
   1. Description: Hypersecretion of growth hormone by the anterior pituitary gland in an adult; caused primarily by pituitary tumors
   2. Assessment
      a. Large hands and feet
      b. Thickening and protrusion of the jaw
      c. Arthritic changes and joint pain, impingement syndromes
      d. Visual disturbances
      e. Diaphoresis
      f. Oily, rough skin
      g. Organomegaly
      h. Hypertension, atherosclerosis, cardiomegaly, heart failure
      i. Dysphagia
      j. Deepening of the voice
      k. Thickening of the tongue, narrowing of the airway, sleep apnea
      l. Hyperglycemia
      m. Colon polyps, increased colon cancer risk
   3. Interventions
      a. Provide pharmacological interventions to suppress GH or to block the action of GH.
      b. Prepare the client for radiation of the pituitary gland or for stereotactic radiosurgery if prescribed.
      c. Prepare the client for hypophysectomy if planned.
      d. Provide pharmacological and nonpharmacological interventions for joint pain.
      e. Provide emotional support to the client and family, and encourage the client and family to express feelings related to disturbed body image.

C. Hypophysectomy (pituitary adenectomy, sublabial transsphenoidal pituitary surgery)
   1. Description
      a. Removal of a pituitary tumor via craniotomy or a sublabial transsphenoidal (endoscopic transnasal) approach (the latter approach is preferred because it is associated with fewer complications)
      b. Complications for craniotomy include increased intracranial pressure, bleeding, meningitis, and hypopituitarism.
      c. Complications for the sublabial transsphenoidal surgery include cerebrospinal fluid leak, infection, diabetes insipidus, and hypopituitarism.
      d. If the sublabial approach is used, an incision is made along the gum line of the inner upper lip.
   2. Postoperative interventions
      a. Initial postoperative care is similar to craniotomy care (see Chapter 59).
      b. Monitor vital signs, neurological status, and level of consciousness.

Telegram & Insta: NCLEX_RN_Edu

c. Elevate the head of the bed.
d. Monitor for increased intracranial pressure.
e. Instruct the client to avoid sneezing, coughing, and blowing the nose.
f. Monitor for bleeding.
g. Monitor for and report signs of temporary diabetes insipidus; monitor intake and output, and report excessive urinary output.
h. If the entire pituitary is removed, clients will require lifelong replacement of ADH, cortisol, and thyroid hormone.
i. Monitor for and report signs of infection and meningitis.
j. Administer antibiotics, analgesics, and antipyretics as prescribed.
k. Perform oral care, which may include mouth rinses, every 4 hours. Clients may be instructed to avoid using a toothbrush or to brush teeth gently with an ultrasoft toothbrush for 10 days to 2 weeks after surgery.
l. Instruct the client in the administration of prescribed medications.

⚠ Following transsphenoidal hypophysectomy, monitor for and report postnasal drip or clear nasal drainage, which might indicate a cerebrospinal fluid leak. Clear drainage should be checked for glucose.

D. Diabetes insipidus

1. Description
   a. Hyposecretion of ADH by the posterior pituitary gland caused by stroke, trauma, or surgery, or it may be idiopathic
   b. Kidney tubules fail to reabsorb water.
   c. In central diabetes insipidus there is decreased ADH production.
   d. In nephrogenic diabetes insipidus, ADH production is adequate, but the kidneys do not respond appropriately to the ADH.
2. Assessment
   a. Excretion of large amounts of dilute urine
   b. Polydipsia
   c. Dehydration (decreased skin turgor and dry mucous membranes)
   d. Inability to concentrate urine
   e. Low urinary specific gravity
   f. Fatigue
   g. Muscle pain and weakness
   h. Headache
   i. Postural hypotension that may progress to vascular collapse without rehydration
   j. Tachycardia
3. Interventions
   a. Monitor vital signs and neurological and cardiovascular status.
   b. Provide a safe environment, particularly for the client with postural hypotension.
   c. Monitor electrolyte values and for signs of dehydration.
   d. Maintain client intake of adequate fluids; IV hypotonic saline may be prescribed to replace urinary losses.
   e. Monitor intake and output, weight, serum osmolality, and specific gravity of urine for excessive urinary output, weight loss, and low urinary specific gravity.
   f. Instruct the client to avoid foods or liquids that produce diuresis.
   g. Vasopressin or desmopressin acetate may be prescribed; these are used when the ADH deficiency is severe or chronic.
   h. Instruct the client in the administration of medications as prescribed; desmopressin acetate may be administered by subcutaneous injection, intravenously, intranasally, or orally; watch for signs of water intoxication, indicating overtreatment.
   i. Instruct the client to wear a MedicAlert bracelet.

E. Syndrome of inappropriate antidiuretic hormone secretion (SIADH)

1. Description
   a. Condition of hyperfunctioning of the posterior pituitary gland in which excess ADH is released, but not in response to the body's need for it
   b. Causes include trauma, stroke, malignancies (often in the lungs or pancreas), medications, and stress. Treatment is directed at correcting the cause.
   c. The syndrome results in increased intravascular volume, water intoxication, and dilutional hyponatremia.
   d. May cause cerebral edema, and the client is at risk for seizures.
2. Assessment
   a. Signs of fluid volume overload
   b. Changes in level of consciousness and in mental status
   c. Weight gain without edema
   d. Hypertension
   e. Tachycardia
   f. Anorexia, nausea, and vomiting
   g. Hyponatremia
   h. Low urinary output and concentrated urine
3. Interventions
   a. Monitor vital signs and cardiac and neurological status.
   b. Provide a safe environment, particularly for the client with changes in level of consciousness or mental status.
   c. Monitor for signs of increased intracranial pressure.
   d. Implement seizure precautions.

BOX 47.7 Adrenal Gland Problems

Adrenal Cortex
- Addison's disease
- Primary hyperaldosteronism (Conn's syndrome)
- Cushing's disease
- Cushing's syndrome

Adrenal Medulla
- Pheochromocytoma

TABLE 47.1 Assessment: Addison's Disease and Cushing's Disease and Cushing's Syndrome

Addison's Disease	Cushing's Disease and Cushing's Syndrome
Lethargy, fatigue, and muscle weakness	Generalized muscle wasting and weakness
Gastrointestinal disturbances	Moon face, buffalo hump
Weight loss	Truncal obesity with thin extremities, supraclavicular fat pads; weight gain
Menstrual changes; impotence	Hirsutism (masculine characteristics)
Hypoglycemia, hyponatremia	Hyperglycemia, hypernatremia
Hyperkalemia, hypercalcemia	Hypokalemia, hypocalcemia
Hypotension	Hypertension
Hyperpigmentation of skin (bronzed) with primary disease	Fragile skin that bruises easily Reddish-purple striae on the abdomen and upper thighs

Adapted from Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems*. (11th ed.). St. Louis: Elsevier. pp. 1162-1163.

e. Elevate the head of the bed a maximum of 10 degrees to promote venous return and decrease baroreceptor-induced ADH release.
f. Monitor intake and output and obtain weight daily.
g. Monitor fluid and electrolyte balance. Chronic SIADH may prompt restriction of fluid to 800-1000 mL/day.
h. Monitor serum and urine osmolality.
i. Restrict fluid intake as prescribed.
j. Administer IV fluids (usually normal saline [NS] or hypertonic saline) as prescribed; monitor IV fluids carefully because of the risk for fluid volume overload.
k. Loop diuretics may be prescribed to promote diuresis, but only if serum sodium is at least 125 mEq/L (125 mmol/L); potassium replacement may be necessary if loop diuretics are prescribed.
l. Vasopressin antagonists may be prescribed to decrease the renal response to ADH.

IV. Adrenal Gland Problems (Box 47.7)

A. Adrenal cortex insufficiency (Addison's disease)
1. Primary adrenal insufficiency
a. Also known as **Addison's disease,** refers to hyposecretion of adrenal cortex hormones (glucocorticoids, mineralocorticoids, and androgen); autoimmune destruction is a common cause.
b. Requires lifelong replacement of glucocorticoids and possibly of mineralocorticoids if significant hyposecretion occurs; the condition is fatal if left untreated.
2. Secondary adrenal insufficiency is caused by hyposecretion of ACTH from the anterior pituitary gland; mineralocorticoid release is spared.
3. Loss of glucocorticoids in Addison's disease leads to decreased vascular tone, decreased vascular response to the catecholamines epinephrine and norepinephrine, and decreased gluconeogenesis.
4. In Addison's disease, loss of the mineralocorticoid aldosterone leads to dehydration, hypotension, hyponatremia, and hyperkalemia.
5. Assessment (Table 47.1)
6. Interventions
a. Monitor vital signs (particularly for hypotension), for weight loss, and intake and output.
b. Monitor white blood cell (WBC) count; blood glucose; and potassium, sodium, and calcium levels.
c. Administer glucocorticoid and/or mineralocorticoid medications as prescribed.
d. Observe for **addisonian crisis** caused by stress, infection, trauma, or surgery.
7. Client education
a. Need for lifelong glucocorticoid replacement and possibly lifelong mineralocorticoid replacement
b. Corticosteroid replacement will need to be increased during times of stress.
c. Avoid individuals with an infection.
d. Avoid strenuous exercise and stressful situations.
e. Avoid over-the-counter medications.
f. Diet should be high in protein and carbohydrates; clients taking glucocorticoids should be prescribed calcium and vitamin D supplements to maintain normal levels and to protect against corticosteroid-induced osteoporosis; some clients taking mineralocorticoids may be prescribed a diet high in sodium.
g. Wear a MedicAlert bracelet.
h. Report signs and symptoms of complications, such as underreplacement and overreplacement of corticosteroid hormones.

Telegram & Insta: NCLEX_RN_Edu

BOX 47.8 Addisonian Crisis

- A life-threatening disorder caused by acute adrenal insufficiency
- Precipitated by stress, infection, trauma, surgery, or abrupt withdrawal of exogenous corticosteroid use
- Can cause hyponatremia, hyperkalemia, hypoglycemia, and hypovolemic shock

B. Addisonian crisis

1. Description (Box 47.8)
2. Assessment
   - **a.** Severe headache
   - **b.** Severe abdominal, leg, and lower back pain
   - **c.** Generalized weakness
   - **d.** Irritability and confusion
   - **e.** Severe hypotension
   - **f.** Shock
3. Interventions
   - **a.** Prepare to administer high-dose hydrocortisone replacement intravenously as prescribed.
   - **b.** Administer IV fluids as prescribed to replace fluids and restore electrolyte balance.
   - **c.** Following resolution of the crisis, administer glucocorticoid and mineralocorticoid orally as prescribed.
   - **d.** Monitor vital signs, particularly blood pressure.
   - **e.** Monitor neurological status, noting irritability and confusion.
   - **f.** Monitor intake and output.
   - **g.** Monitor laboratory values, particularly sodium, potassium, and blood glucose levels.
   - **h.** Protect the client from infection.
   - **i.** Maintain bed rest and provide a quiet environment.

Clients taking exogenous corticosteroids must establish a plan with their PHCPs or endocrinologist for increasing their corticosteroids during times of stress.

C. Cushing's syndrome and Cushing's disease (hypercortisolism)

1. Cushing's syndrome
   - **a.** A metabolic disorder resulting from the chronic and excessive production of cortisol by the adrenal cortex or from the administration of glucocorticoids in large doses for several weeks or longer (exogenous or iatrogenic)
   - **b.** ACTH-secreting tumors (most often of the lung, pancreas, or gastrointestinal [GI] tract) can cause Cushing's syndrome.
2. Cushing's disease is a metabolic disorder characterized by abnormally increased secretion (endogenous) of cortisol, caused by increased amounts of ACTH secreted by the pituitary gland.
3. Assessment (Fig. 47.2; see Table 47.1)
4. Interventions
   - **a.** Monitor vital signs, particularly blood pressure.
   - **b.** Monitor intake and output and weight.
   - **c.** Monitor laboratory values, particularly WBC count and serum glucose, sodium, potassium, and calcium levels.
   - **d.** Prepare the client for radiation as prescribed if the condition results from a pituitary adenoma.
   - **e.** Administer chemotherapeutic agents as prescribed for inoperable adrenal tumors.
   - **f.** Prepare the client for removal of the pituitary tumor (hypophysectomy, sublabial transsphenoidal adenectomy) if the condition results from increased pituitary secretion of ACTH.
   - **g.** Prepare the client for **adrenalectomy** if the condition results from an adrenal adenoma; glucocorticoid replacement may be required following adrenalectomy.
   - **h.** Clients requiring lifelong glucocorticoid replacement following adrenalectomy should obtain instructions from their PHCPs about increasing their glucocorticoid during times of stress.
   - **i.** Assess for and protect against postoperative thrombus formation; Cushing's syndrome predisposes to thromboemboli.
   - **j.** Allow the client to discuss feelings related to body appearance.
   - **k.** Instruct the client about the need to wear a MedicAlert bracelet.

FIG. 47.2 Typical appearance of a client with Cushing's syndrome. Note truncal obesity, moon face, buffalo hump, thinner arms and legs, and abdominal striae. (From Wenig, Heffess, Adair, 1997.)

Telegram & Insta: NCLEX_RN_Edu

Addison's disease is characterized by the hyposecretion of adrenal cortex hormones, whereas Cushing's syndrome and Cushing's disease are characterized by a hypersecretion of glucocorticoids.

D. Primary hyperaldosteronism (Conn's syndrome)

1. Description

a. Hypersecretion of mineralocorticoids (aldosterone) from the adrenal cortex of the adrenal gland

b. Most commonly caused by an adenoma

c. Excess secretion of aldosterone causes sodium and water retention and potassium excretion, leading to hypertension and hypokalemic alkalosis.

2. Assessment

a. Symptoms related to hypokalemia, hypernatremia, and hypertension

b. Headache, fatigue, muscle weakness

c. Cardiac dysrhythmias

d. Paresthesias, tetany

e. Visual changes

f. Glucose intolerance

g. Elevated serum aldosterone levels

3. Interventions

a. Monitor vital signs, particularly blood pressure.

b. Monitor potassium and sodium levels.

c. Monitor intake and output and urine for specific gravity.

d. Monitor for hyperkalemia, particularly for clients with impaired renal function or excessive potassium intake, because potassium-retaining diuretics and aldosterone antagonists may be prescribed to promote fluid balance and control hypertension.

e. Administer potassium supplements as prescribed to treat hypokalemia; clients taking potassium-retaining diuretics and potassium supplementation are at risk for hyperkalemia.

f. Prepare the client for adrenalectomy.

g. Maintain sodium restriction, if prescribed, preoperatively.

h. Administer glucocorticoids preoperatively, as prescribed, to prevent adrenal hypofunction and prepare for stress of surgery.

i. Monitor the client for adrenal insufficiency postoperatively.

j. Instruct the client regarding the need for glucocorticoid therapy following adrenalectomy.

k. Instruct the client about the need to wear a MedicAlert bracelet.

E. Pheochromocytoma

1. Description

a. Catecholamine-producing tumor usually found in the adrenal medulla, but extraadrenal locations include the chest, bladder, abdomen, and brain; typically is a benign tumor but can be malignant

b. Excessive amounts of epinephrine and norepinephrine are secreted.

c. Diagnostic test includes a 24-hour urine collection for fractionated metanephrines and catecholamines and creatinine.

d. Surgical removal of the adrenal gland is the primary treatment.

e. Symptomatic treatment is initiated if surgical removal is not possible.

f. The complications associated with pheochromocytoma include hypertensive crisis; hypertensive retinopathy and nephropathy, cardiac enlargement, and dysrhythmias; heart failure; myocardial infarction; increased platelet aggregation; and stroke.

g. Death can occur from shock, stroke, renal failure, dysrhythmias, or dissecting aortic aneurysm.

2. Assessment

a. Paroxysmal or sustained hypertension

b. Severe headaches

c. Palpitations

d. Flushing and profuse diaphoresis

e. Pain in the chest or abdomen with nausea and vomiting

f. Heat intolerance

g. Weight loss

h. Tremors

i. Hyperglycemia

3. Interventions (see Clinical Judgment: Take Action Box)

a. Monitor vital signs, particularly blood pressure and heart rate.

b. Monitor for hypertensive crisis; monitor for complications that can occur with hypertensive crisis, such as stroke, cardiac dysrhythmias, and myocardial infarction.

c. Instruct the client not to smoke, drink caffeine-containing beverages, or change position suddenly.

d. Prepare to administer α-adrenergic blocking agents and β-adrenergic blocking agents as prescribed to control hypertension. α-Adrenergic blocking agents are started 7 to 10 days before β-adrenergic blocking agents.

e. Monitor serum glucose level.

f. Promote rest and a nonstressful environment.

g. Provide a diet high in calories, vitamins, and minerals.

h. Prepare the client for adrenalectomy.

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: TAKE ACTION

A client with pheochromocytoma suddenly develops a severe headache, dizziness, and blurred vision. The nurse checks the client's vital signs and notes that the client's respiratory rate is 28 breaths per minute and the client is dyspneic. The blood pressure is 220/140 mm Hg. The nurse analyzes these cues, determines that the client is developing hypertensive crisis, and takes the following actions:

- Places the client in a semi-Fowler's position
- Notifies the primary health care provider
- Prepares to administer oxygen
- Starts an intravenous infusion of 0.9% normal saline (NS) solution and infuses it slowly to prevent fluid overload (which would further increase blood pressure)
- Administers intravenous medications to lower blood pressure
- Monitors the blood pressure frequently for a response, and monitors for complications

BOX 47.9 Adrenalectomy

- Surgical removal of an adrenal gland
- Lifelong glucocorticoid and mineralocorticoid replacement is necessary with bilateral adrenalectomy.
- Temporary glucocorticoid replacement, usually up to 2 years, is necessary after a unilateral adrenalectomy.
- Catecholamine levels drop as a result of surgery, which can result in cardiovascular collapse, hypotension, and shock, and the client needs to be monitored closely.
- Hemorrhage also can occur because of the high vascularity of the adrenal glands.

⚠ For the client with pheochromocytoma, avoid stimuli that can precipitate a hypertensive crisis, such as increased abdominal pressure and abdominal palpation.

F. Adrenalectomy
1. Description (Box 47.9)
2. Preoperative interventions
   a. Monitor electrolyte levels and correct electrolyte imbalances.
   b. Assess for dysrhythmias.
   c. Monitor for hyperglycemia.
   d. Protect the client from infections.
   e. Administer glucocorticoids as prescribed.
3. Postoperative interventions
   a. Monitor vital signs.
   b. Monitor intake and output; if the urinary output is lower than 30 mL/hr, notify the PHCP or nephrologist, because this may result in acute kidney injury and indicate impending shock.
   c. Monitor weight daily.
   d. Monitor electrolyte and serum glucose levels.
   e. Monitor for signs of hemorrhage and shock, particularly during the first 24 to 48 hours.
   f. Monitor for manifestations of adrenal insufficiency (see Table 47.1).
   g. Assess the dressing for drainage.
   h. Monitor for paralytic ileus.
   i. Administer IV fluids as prescribed to maintain blood volume.
   j. Administer glucocorticoids and mineralocorticoids as prescribed.
   k. Administer pain medication as prescribed.
   l. Provide pulmonary interventions to prevent atelectasis (coughing and deep breathing, incentive spirometry, splinting of incision).
   m. Instruct the client in the importance of hormone replacement therapy following surgery.
   n. Instruct the client regarding signs and symptoms of complications such as underreplacement and overreplacement of hormones.
   o. Instruct the client regarding the need to wear a MedicAlert bracelet.

V. Thyroid Gland Problems

A. Hypothyroidism

1. Description
   a. Hypothyroid state resulting from hyposecretion of thyroid hormones and characterized by a decreased rate of body metabolism
   b. The T_4 is low and the TSH is elevated.
   c. In primary hypothyroidism, the source of dysfunction is the thyroid gland, and the thyroid cannot produce the necessary amount of hormones. In secondary hypothyroidism, the thyroid is not being stimulated by the pituitary to produce hormones.
2. Assessment (Table 47.2)
3. Interventions
   a. Monitor vital signs, including heart rate and rhythm.
   b. Administer thyroid replacement; levothyroxine sodium is most commonly prescribed.
   c. Instruct the client about thyroid replacement therapy and about the clinical manifestations of both hypothyroidism and hyperthyroidism related to underreplacement or overreplacement of the hormone.
   d. Instruct the client in a diet low in calories, cholesterol, and saturated fat; discuss a daily exercise program such as walking.
   e. Assess the client for constipation; provide roughage and fluids to prevent constipation.
   f. Provide a warm environment for the client.
   g. Avoid sedatives and opioid analgesics because of increased sensitivity to these medications; may precipitate myxedema coma.

Telegram & Insta: NCLEX_RN_Edu

TABLE 47.2 Assessment: Hypothyroidism and Hyperthyroidism

Hypothyroidism	Hyperthyroidism
Lethargy and fatigue	Personality changes such as irritability, agitation, and mood swings
Weakness, muscle aches, paresthesias	Nervousness and fine tremors of the hands Weakness, muscle aches, paresthesias
Intolerance to cold	Heat intolerance
Weight gain	Weight loss
Dry skin and hair and loss of body hair	Smooth, soft skin and hair
Bradycardia	Palpitations, cardiac dysrhythmias, such as tachycardia or atrial fibrillation
Constipation	Diarrhea
Generalized puffiness and edema around the eyes and face (myxedema)	Protruding eyeballs (exophthalmos) may be present (see Fig. 47.3)
Forgetfulness and loss of memory	Diaphoresis
Menstrual disturbances	Hypertension
Goiter may or may not be present	Enlarged thyroid gland (goiter)
Cardiac enlargement, tendency to develop heart failure	

Adapted from Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems*. (11th ed.). St. Louis: Elsevier. p. 1160.

BOX 47.10 Myxedema Coma

- A rare but serious disorder that results from persistently low thyroid production
- Coma can be precipitated by acute illness, rapid withdrawal of thyroid medication, anesthesia and surgery, hypothermia, or the use of sedatives and opioid analgesics.

h. Monitor for overdose of thyroid medications, characterized by tachycardia, chest pain, restlessness, nervousness, and insomnia.
i. Instruct the client to report episodes of chest pain or other signs of overdose immediately.

B. Myxedema coma

1. Description (Box 47.10)
2. Assessment
   - **a.** Hypotension
   - **b.** Bradycardia
   - **c.** Hypothermia
   - **d.** Hyponatremia
   - **e.** Hypoglycemia
   - **f.** Generalized edema
   - **g.** Respiratory failure
   - **h.** Coma
3. Interventions
   - **a.** Maintain a patent airway.
   - **b.** Institute aspiration precautions.
   - **c.** Administer IV fluids (normal or hypertonic saline) as prescribed.
   - **d.** Administer levothyroxine sodium intravenously as prescribed.
   - **e.** Administer glucose intravenously as prescribed.
   - **f.** Administer corticosteroids as prescribed.
   - **g.** Assess the client's temperature hourly.
   - **h.** Monitor blood pressure frequently.
   - **i.** Keep the client warm.
   - **j.** Monitor for changes in mental status.
   - **k.** Monitor electrolyte and glucose levels.

FIG. 47.3 Exophthalmos. Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1256.

C. Hyperthyroidism

1. Description
   - **a.** Hyperthyroid state resulting from hypersecretion of thyroid hormones (T_3 and T_4)
   - **b.** Characterized by an increased rate of body metabolism
   - **c.** A common cause is Graves' disease, also known as toxic diffuse goiter.
   - **d.** Clinical manifestations are referred to as *thyrotoxicosis.*
   - **e.** The T_3 and T_4 are usually elevated and the TSH level is low.
2. Assessment (see Table 47.2; Fig. 47.3)
3. Interventions
   - **a.** Provide adequate rest.
   - **b.** Administer sedatives as prescribed.
   - **c.** Provide a cool and quiet environment.
   - **d.** Obtain weight daily.
   - **e.** Provide a high-calorie diet.
   - **f.** Avoid the administration of stimulants.

Telegram & Insta: NCLEX_RN_Edu

g. Administer antithyroid medications, such as methimazole or propylthiouracil, which block thyroid synthesis as prescribed.
h. Administer iodine preparations that inhibit the release of thyroid hormone as prescribed.
i. Administer propranolol for tachycardia as prescribed.
j. Prepare the client for radioactive iodine therapy, as prescribed, to destroy thyroid cells.
k. Prepare the client for subtotal thyroidectomy if prescribed.
l. Elevate the head of the bed of a client experiencing exophthalmos; in addition, instruct on low-salt diet, administer artificial tears, encourage the use of dark glasses, and tape eyelids closed at night if necessary.
m. Allow the client to express concerns about body image changes.

D. Thyroid storm

1. Description (Box 47.11)
2. Assessment
a. Elevated temperature (fever)
b. Tachycardia
c. Systolic hypertension
d. Nausea, vomiting, and diarrhea
e. Agitation, tremors, anxiety
f. Irritability, agitation, restlessness, confusion, and seizures as the condition progresses
g. Delirium and coma
3. Interventions
a. Maintain a patent airway and adequate ventilation.
b. Administer antithyroid medications, iodides, propranolol, and glucocorticoids as prescribed.
c. Monitor vital signs.
d. Monitor continually for cardiac dysrhythmias.
e. Administer nonsalicylate antipyretics as prescribed (salicylates increase free thyroid hormone levels).
f. Use a cooling blanket to decrease temperature as prescribed.

E. Thyroidectomy

1. Description
a. Removal of the thyroid gland
b. Performed when persistent hyperthyroidism exists
c. Subtotal thyroidectomy, removal of a portion of the thyroid gland, is the preferred surgical intervention.
2. Preoperative interventions
a. Obtain vital signs and weight.
b. Assess electrolyte levels.
c. Assess for hyperglycemia.
d. Instruct the client in how to perform coughing and deep-breathing exercises and how to support the neck in the postoperative period when coughing and moving.
e. Administer antithyroid medications, iodides, propranolol, and glucocorticoids as prescribed to prevent the occurrence of thyroid storm.
3. Postoperative interventions
a. Monitor for respiratory distress.
b. Have a tracheotomy set, oxygen, and suction at the bedside.
c. Limit client talking, and assess level of hoarseness.
d. Avoid neck flexion and stress on the suture line.
e. Monitor for laryngeal nerve damage, as evidenced by airway obstruction, dysphonia, high-pitched voice, stridor, dysphagia, and restlessness.
f. Monitor for signs of hypocalcemia and tetany, which can be caused by trauma to the parathyroid gland (Box 47.12).
g. Prepare to administer calcium gluconate as prescribed for tetany.
h. Monitor for thyroid storm.

Following thyroidectomy, maintain the client in a semi-Fowler's position. Monitor the surgical site for edema and for signs of bleeding and check the dressing anteriorly and at the back of the neck. Monitor for inflammation, which may block the airway. An emergency tracheostomy kit should be at the bedside.

BOX 47.11 Thyroid Storm

- This acute and life-threatening condition occurs in a client with uncontrollable hyperthyroidism.
- It can be caused by manipulation of the thyroid gland during surgery and the release of thyroid hormone into the bloodstream; it also can occur from severe infection and stress.
- Antithyroid medications, beta blockers, glucocorticoids, and iodides may be administered to the client before thyroid surgery to prevent its occurrence.

BOX 47.12 Signs of Tetany

- Cardiac dysrhythmias
- Carpopedal spasm
- Dysphagia
- Muscle and abdominal cramps
- Numbness and tingling of the face and extremities
- Positive Chvostek's sign
- Positive Trousseau's sign
- Visual disturbances (photophobia)
- Wheezing and dyspnea (bronchospasm, laryngospasm)
- Seizures

Telegram & Insta: NCLEX_RN_Edu

VI. Parathyroid Gland Problems

A. Hypoparathyroidism

1. Description
   - a. Condition caused by hyposecretion of parathyroid hormone by the parathyroid gland
   - b. Can occur following thyroidectomy because of removal of parathyroid tissue
2. Assessment
   - a. Hypocalcemia and hyperphosphatemia
   - b. Numbness and tingling in the face
   - c. Muscle cramps and cramps in the abdomen or in the extremities
   - d. Positive Trousseau's sign or Chvostek's sign
   - e. Signs of overt tetany, such as bronchospasm, laryngospasm, carpopedal spasm, dysphagia, photophobia, cardiac dysrhythmias, seizures
   - f. Hypotension
   - g. Anxiety, irritability, depression
3. Interventions
   - a. Monitor vital signs.
   - b. Monitor for signs of hypocalcemia and tetany.
   - c. Initiate seizure precautions.
   - d. Place a tracheotomy set, oxygen, and suctioning equipment at the bedside.
   - e. Prepare to administer calcium gluconate intravenously for hypocalcemia.
   - f. Provide a high-calcium, low-phosphorus diet.
   - g. Instruct the client in the administration of calcium supplements as prescribed.
   - h. Instruct the client in the administration of vitamin D supplements as prescribed; vitamin D enhances the absorption of calcium from the gastrointestinal (GI) tract.
   - i. Instruct the client in the use of thiazide diuretics, if prescribed, to protect the kidney if vitamin D is also taken.
   - j. Instruct the client in the administration of phosphate binders as prescribed to promote the excretion of phosphate through the GI tract.
   - k. Instruct the client to wear a MedicAlert bracelet.

B. Hyperparathyroidism

1. Description: Condition caused by hypersecretion of parathyroid hormone (PTH) by the parathyroid gland
2. Assessment
   - a. Hypercalcemia and hypophosphatemia
   - b. Fatigue and muscle weakness
   - c. Skeletal pain and tenderness
   - d. Bone deformities that result in pathological fractures
   - e. Anorexia, nausea, vomiting, epigastric pain
   - f. Weight loss
   - g. Constipation
   - h. Hypertension
   - i. Cardiac dysrhythmias
   - j. Renal stones
3. Interventions
   - a. Monitor vital signs, particularly blood pressure.
   - b. Monitor for cardiac dysrhythmias.
   - c. Monitor intake and output and for signs of renal stones.
   - d. Monitor for skeletal pain; move the client slowly and carefully.
   - e. Encourage fluid intake.
   - f. Administer furosemide as prescribed to lower calcium levels.
   - g. Administer NS intravenously as prescribed to maintain hydration.
   - h. Administer phosphates, which interfere with calcium reabsorption, as prescribed.
   - i. Administer calcitonin as prescribed to decrease skeletal calcium release and increase renal excretion of calcium.
   - j. Administer IV or oral bisphosphonates to inhibit bone resorption.
   - k. Monitor calcium and phosphorus levels.
   - l. Prepare the client for parathyroidectomy as prescribed.
   - m. Encourage a high-fiber, moderate-calcium diet.
   - n. Emphasize the importance of an exercise program and avoiding prolonged inactivity.

C. Parathyroidectomy

1. Description: Removal of one or more of the parathyroid glands
   - a. Endoscopic radioguided parathyroidectomy with autotransplantation is a common procedure.
   - b. Parathyroid tissue is transplanted in the forearm or near the sternocleidomastoid muscle, allowing PTH secretion to continue.
2. Preoperative interventions
   - a. Monitor electrolytes, calcium, phosphate, and magnesium levels.
   - b. Ensure that calcium levels are decreased to near-normal values.
   - c. Inform the client that talking may be painful for the first day or two after surgery.
3. Postoperative interventions
   - a. Monitor for respiratory distress.
   - b. Place a tracheotomy set, oxygen, and suctioning equipment at the bedside.
   - c. Monitor vital signs.
   - d. Position the client in semi-Fowler's position.
   - e. Assess neck dressing for bleeding.
   - f. Monitor for hypocalcemic crisis, as evidenced by tingling and twitching in the extremities and face.
   - g. Assess for positive Trousseau's sign or Chvostek's sign, which indicates tetany.

Telegram & Insta: NCLEX_RN_Edu

h. Monitor for changes in voice pattern and hoarseness.
i. Monitor for laryngeal nerve damage.
j. Instruct the client in the administration of calcium and vitamin D supplements as prescribed.

VII. Problems of the Pancreas

A. Diabetes mellitus

1. Description
a. Chronic disorder of impaired carbohydrate, protein, and lipid metabolism caused by a deficiency of insulin or insulin resistance
b. An absolute or relative deficiency of insulin results in hyperglycemia.
c. Type 1 diabetes mellitus is a nearly absolute deficiency of insulin (primary beta cell destruction); if insulin is not given, fats are metabolized for energy, resulting in ketonemia (acidosis).
d. Type 2 diabetes mellitus is a relative lack of insulin or resistance to the action of insulin; usually, insulin is sufficient to stabilize fat and protein metabolism but not carbohydrate metabolism.
e. Metabolic syndrome is also known as syndrome X, and the individual has coexisting risk factors for developing type 2 diabetes mellitus; these risk factors include abdominal obesity, hyperglycemia, hypertension, high triglyceride level, and a lowered HDL (high-density lipoprotein) cholesterol level.
f. Diabetes mellitus can lead to chronic health problems and early death as a result of complications that occur in the large and small blood vessels in tissues and organs.
g. Macrovascular complications include coronary artery disease, cardiomyopathy, hypertension, cerebrovascular disease, and peripheral vascular disease. (Refer to Chapter 53 for information on cardiovascular problems.)
h. Microvascular complications include retinopathy, nephropathy, and neuropathy.
i. Infection is also a concern because of reduced healing ability.
j. Erectile dysfunction can also occur as a result of the disease.

Obesity is a major risk factor for diabetes mellitus.

2. Assessment
a. Polyuria, polydipsia, polyphagia (more common in type 1 diabetes mellitus)
b. Hyperglycemia
c. Weight loss (common in type 1 diabetes mellitus, rare in type 2 diabetes mellitus)
d. Blurred vision
e. Slow wound healing
f. Vaginal infections
g. Weakness and paresthesias
h. Signs of inadequate circulation to the feet
i. Signs of accelerated atherosclerosis (renal, cerebral, cardiac, peripheral)

3. Diet
a. The diabetic client's diet should take into account weight, medication, activity level, and other health problems.
b. Day-to-day consistency in timing and amount of food intake helps control the blood glucose level.
c. As prescribed by the PHCP or endocrinologist, the client may be advised to follow the recommendations of the American Diabetic Association diet or U.S. dietary guidelines (MyPlate; www.myplate.gov) issued by the U.S. Departments of Agriculture and Health and Human Services.
d. Carbohydrate counting may be a simpler approach for some clients; it focuses on the total grams of carbohydrates eaten per meal. The client may be more compliant with carbohydrate counting, resulting in better glycemic control; it is usually necessary for clients undergoing intense insulin therapy.
e. Incorporate the diet into individual client needs, lifestyle, and cultural and socioeconomic patterns.

4. Exercise
a. Exercise lowers the blood glucose level, encourages weight loss, reduces cardiovascular risks, improves circulation and muscle tone, decreases total cholesterol and triglyceride levels, and decreases insulin resistance and glucose intolerance.
b. Instruct the client in dietary adjustments when exercising; dietary adjustments are individualized.
c. If the client requires extra food during exercise to prevent hypoglycemia, it need not be deducted from the regular meal plan.
d. If the blood glucose level is higher than 250 mg/dL (13.9 mmol/L) and urinary ketones (type 1 diabetes mellitus) are present, the client is instructed not to exercise until the blood glucose level is closer to normal and urinary ketones are absent.
e. The client should try to exercise at the same time each day and should exercise when glucose from the meal is peaking, not when insulin or glucose-lowering medications are peaking.
f. Insulin should not be injected into an area of the body that will be exercised following injection, as exercise speeds absorption.

Telegram & Insta: NCLEX_RN_Edu

Instruct the client with diabetes mellitus to monitor the blood glucose level before, during, and after exercising.

5. Oral hypoglycemic medications: Oral medications are prescribed for clients with diabetes mellitus type 2 when diet and weight control therapy have failed to maintain satisfactory blood glucose levels (Chapter 48).
6. Insulin (refer to Chapter 48 for additional information on insulin)
   a. Insulin is used to treat type 1 diabetes mellitus and may be used to treat type 2 diabetes mellitus when diet, weight control therapy, and oral hypoglycemic agents have failed to maintain satisfactory blood glucose levels.
   b. Illness, infection, and stress increase the blood glucose level and the need for insulin; insulin should not be withheld during times of illness, infection, or stress because hyperglycemia and **diabetic ketoacidosis** can result.
   c. The peak action time of insulin is important to explain to the client because of the possibility of hypoglycemic reactions occurring during this time.

Regular insulin (U-100 strength) can be administered via IV injection (IV push). Regular insulin (U-100) and the short-duration insulins (lispro, aspart, and glulisine) can be administered (under close medical supervision) via IV infusion.

B. Complications of insulin therapy
   1. Local allergic reactions
      a. Redness, swelling, tenderness, and induration or a wheal at the site of injection may occur 1 to 2 hours after administration.
      b. Reactions usually occur during the early stages of insulin therapy.
      c. Instruct the client to cleanse the skin with alcohol before injection.
   2. Insulin lipodystrophy
      a. The development of fibrous fatty masses at the injection site caused by repeated use of an injection site; use of human insulin helps prevent this.
      b. Instruct the client to avoid injecting insulin into affected sites.
      c. Instruct the client about the importance of rotating insulin injection sites. Systematic rotation within one anatomical area is recommended to prevent lipodystrophy; the client should be instructed not to use the same site more than once in a 2- to 3-week period. Injections should be 1.5 inches (3.8 cm) apart within the anatomical area.
   3. **Dawn phenomenon**
      a. Dawn phenomenon is characterized by hyperglycemia upon morning awakening that results from excessive early morning release of GH and cortisol.
      b. Treatment requires an increase in the client's insulin dose or a change in the time of insulin administration.
   4. **Somogyi phenomenon**
      a. Normal or elevated blood glucose levels are present at bedtime; hypoglycemia occurs at about 2 to 3 a.m., which causes an increase in the production of counterregulatory hormones.
      b. By about 7 a.m., in response to the counterregulatory hormones, the blood glucose rebounds significantly to the hyperglycemic range.
      c. Treatment includes a decrease in the client's insulin dose or increase in the bedtime snack, or both.
      d. Clients experiencing the Somogyi phenomenon may complain of early morning headaches, night sweats, or nightmares caused by the early morning hypoglycemia.

C. Insulin administration
   1. Subcutaneous injections and mixing insulin: See Chapter 48.
   2. Insulin pumps
      a. Continuous subcutaneous insulin infusion is administered by an externally worn device that contains a syringe and pump; different types of pumps are available and the one selected is based on the client's needs.
      b. The client inserts the needle or Teflon catheter into the subcutaneous tissue (usually on the abdomen or upper arm) and secures it with tape or a transparent dressing; the needle or Teflon catheter is changed at least every 2 to 3 days.
      c. A continuous basal rate of insulin infuses; in addition, on the basis of the blood glucose level, the anticipated food intake, and the activity level, the client delivers a bolus of insulin before each meal.
      d. Both rapid-acting and regular short-acting insulin (buffered to prevent the precipitation of insulin crystals within the catheter) are appropriate for use in these pumps.
   3. Insulin pump and skin sensor
      a. A skin sensor device can be used that monitors the client's blood glucose continuously; the information is transmitted to the pump, which determines the need for insulin, and then the insulin is injected.
      b. The pump holds up to a 3-day supply of insulin and can be disconnected easily if necessary for certain activities such as bathing.

Telegram & Insta: NCLEX_RN_Edu

4. Pancreas transplants
   a. The goal of pancreatic transplantation is to halt or reverse the complications of diabetes mellitus.
   b. Transplantations are performed on a limited number of clients (in general, these are clients who are undergoing kidney transplantation simultaneously).
   c. Immunosuppressive therapy is prescribed to prevent and treat rejection.

D. Self-monitoring of blood glucose level
1. Self-monitoring provides the client with the current blood glucose level and information to maintain good glycemic control.
2. Monitoring requires a finger prick to obtain a drop of blood for testing.
3. Alternative site testing (obtaining blood from the forearm, upper arm, abdomen, thigh, or calf) is available, using specific measurement devices.
4. Tests must be used with caution in clients with diabetic neuropathy.
5. Client instructions (Box 47.13)

E. Urine testing
1. Urine testing for glucose is not a reliable indicator of the blood glucose level and is not used for monitoring purposes.
2. Instruct the client in the procedure for testing for urine ketones.
3. The presence of ketones may indicate impending ketoacidosis.
4. Urine ketone testing should be performed during illness and whenever the client with type 1 diabetes mellitus has persistently elevated blood glucose levels (higher than 250 mg/dL [13.9 mmol/L] or as prescribed for two consecutive testing periods).

BOX 47.13 Client Instructions: Self-Monitoring of Blood Glucose Level

- Use the proper procedure to obtain the sample for determining the blood glucose level.
- Perform the procedure precisely to obtain accurate results.
- Follow the manufacturer's instructions for the glucometer.
- Wash hands before and after performing the procedure to prevent infection.
- If needed, calibrate the monitor as instructed by the manufacturer.
- Check the expiration date on the test strips.
- If the blood glucose level results do not seem reasonable, reread the instructions, reassess technique, check the expiration date of the test strips, and perform the procedure again to verify results.

VIII. Acute Complications of Diabetes Mellitus

A. Hypoglycemia
1. Description
   a. Hypoglycemia occurs when the blood glucose level falls below 70 mg/dL (3.9 mmol/L) or when the blood glucose level drops rapidly from an elevated level.
   b. Hypoglycemia is caused by too much insulin or too large an amount of an oral hypoglycemic agent, too little food, or excessive activity.
   c. The client needs to be instructed always to keep some form of fast-acting simple carbohydrate available (Box 47.14).
   d. If the client has a hypoglycemic reaction and does not have any of the recommended emergency foods available, any available food should be eaten; high-fat foods slow the absorption of glucose, and the hypoglycemic symptoms may not resolve quickly.
   e. Clients who experience frequent episodes of hypoglycemia, older clients, and clients taking β-adrenergic blocking agents may not experience the warning signs of hypoglycemia until the blood glucose level is dangerously low; this phenomenon is termed *hypoglycemia unawareness.*
2. Assessment (Box 47.15)
   a. Mild hypoglycemia: The client remains fully awake but displays adrenergic symptoms; the blood glucose level is lower than 70 mg/dL (3.9 mmol/L).
   b. Moderate hypoglycemia: The client displays symptoms of worsening hypoglycemia; the blood glucose level is usually lower than 40 mg/dL (2.2 mmol/L).
   c. Severe hypoglycemia: The client displays severe neuroglycopenic symptoms; the blood glucose level is usually lower than 20 mg/dL (1.1 mmol/L).

BOX 47.14 Simple Carbohydrates to Treat Hypoglycemia

- Commercially prepared glucose tablets or glucose gel
- 6 to 10 Life Savers or hard candy
- 4 tsp of sugar
- 4 sugar cubes
- 1 Tbsp of honey or syrup
- ½ cup of fruit juice or regular (nondiet) soft drink
- 8 oz (235 mL) of low-fat milk
- 6 saltine crackers
- 3 graham crackers

Telegram & Insta: NCLEX_RN_Edu

3. Interventions (see Clinical Judgment: Take Action Box)

CLINICAL JUDGMENT: TAKE ACTION

A hospitalized client with diabetes mellitus complains of sweating and hunger, and the nurse notes that the client is pale and shaking. The nurse recognizes these cues as a hypoglycemic reaction. Using the 15/15 rule, the nurse takes the following actions:

- Checks the client's blood glucose level
- If the blood glucose is below 70 mg/dL (3.9 mmol/L), administers 15 g of a simple carbohydrate such as ½ cup of fruit juice or 15 g of glucose gel
- Rechecks the blood glucose level in 15 minutes
- If the blood glucose remains below 70 mg/dL (3.9 mmol/L), administers another 15 g of a simple carbohydrate
- Rechecks the blood glucose level in 15 minutes; if still below 70 mg/dL (3.9 mmol/L), treats with an additional 15 g of a simple carbohydrate
- Rechecks the blood glucose level in 15 minutes; if still below 70 mg/dL (3.9 mmol/L), treats with 25 to 50 mL of 50% dextrose intravenously or with 1 mg of glucagon subcutaneously or intramuscularly
- After the blood glucose level has recovered, has the client ingest a snack that includes a complex carbohydrate and a protein
- Documents the client's complaints, actions taken, and outcome
- Explores the precipitating cause of the hypoglycemia with the client
- If the client is experiencing an altered level of consciousness, bypasses oral treatment and starts with injectable glucagon or 50% dextrose

Data from American Diabetes Association. *The 15/15 rule.* Retrieved from American Diabetes Association. Hypoglycemia (Low Blood Sugar). Retrieved from https://www.diabetes.org/diabetes/medication-management/blood-glucose-testing-and-control/hypoglycemia

⚠ Do not attempt to administer oral food or fluids to the client experiencing a severe hypoglycemic reaction who is semiconscious or unconscious and is unable to swallow. This client is at risk for aspiration. For this client, an injection of glucagon is administered subcutaneously, intramuscularly, or intravenously. In the hospital or emergency department, the client may be treated with an IV injection of 25 to 50 mL (12.5 to 25 g) of 50% dextrose in water.

BOX 47.15 Assessment of Hypoglycemia

Mild
- Hunger
- Nervousness
- Palpitations
- Sweating
- Tachycardia
- Tremor

Moderate
- Confusion
- Double vision
- Drowsiness
- Emotional changes
- Headache
- Impaired coordination
- Inability to concentrate
- Irrational or combative behavior
- Light-headedness
- Numbness of the lips and tongue
- Slurred speech

Severe
- Difficulty arousing
- Disoriented behavior
- Loss of consciousness
- Seizures

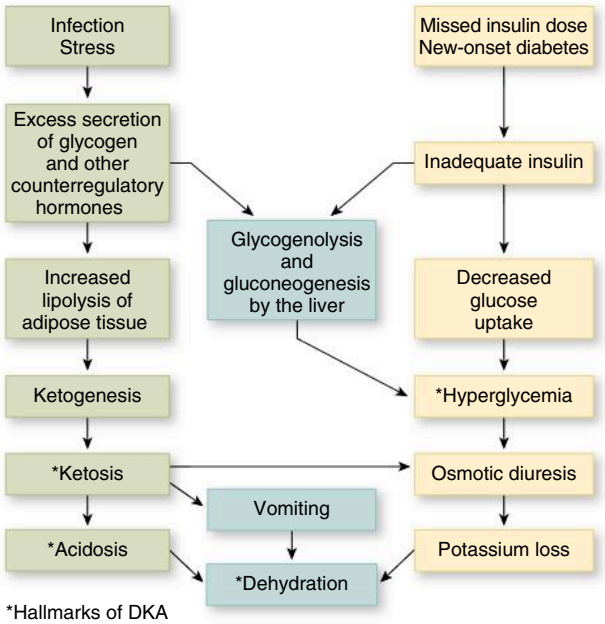

FIG. 47.4 Pathophysiology of diabetic ketoacidosis (DKA).

B. Diabetic ketoacidosis (DKA)

1. Description (Fig. 47.4)
   - **a.** Diabetic ketoacidosis is a life-threatening complication of type 1 diabetes mellitus that develops when a severe insulin deficiency occurs.
   - **b.** The main clinical manifestations include hyperglycemia, dehydration, ketosis, and acidosis.
2. Assessment (Table 47.3)
3. Interventions
   - **a.** Restore circulating blood volume and protect against cerebral, coronary, and renal hypoperfusion.
   - **b.** Treat dehydration with rapid IV infusions of 0.9% or 0.45% NS as prescribed; dextrose is added to IV fluids when the blood glucose level reaches 250 to 300 mg/dL (13.9 to

Telegram & Insta: NCLEX_RN_Edu

TABLE 47.3 Differences Between Diabetic Ketoacidosis and Hyperosmolar Hyperglycemic Syndrome

	Diabetic Ketoacidosis (DKA)	Hyperosmolar Hyperglycemic Syndrome (HHS)
Onset	Sudden	Gradual
Precipitating factors	Infection	Infection
	Other stressors	Other stressors
	Inadequate insulin dose	Poor fluid intake
Manifestations	Ketosis: Kussmaul's respiration, "fruity" breath, nausea, abdominal pain	Altered central nervous system function with neurological symptoms
	Dehydration or electrolyte loss: Polyuria, polydipsia, weight loss, dry skin, sunken eyes, soft eyeballs, lethargy, coma	Dehydration or electrolyte loss: Same as for DKA
Laboratory Findings		
Serum glucose	>300 mg/dL (>16.7 mmol/L)	>800 mg/dL (>44.5 mmol/L)
Osmolarity	Variable	>350 mOsm/kg (>350 mmol/kg)
Serum ketones	Positive at 1:2 dilution	Negative
Serum pH	<7.35	>7.4
Serum HCO_3	<15 mEq/L (<15 mmol/L)	>20 mEq/L (>20 mmol/L)
Serum Na	Low, normal, or high	Normal or low
Serum K	Normal; elevated with acidosis, decreases following hydration	Normal or low
BUN	>20 mg/dL (>7.1 mmol/L); elevated because of dehydration	Elevated
Creatinine	>1.5 mg/dl (>132.5 mcmol/L); elevated because of dehydration	Elevated
Urine ketones	Positive	Negative

BUN, Blood urea nitrogen; *HCO_3,* bicarbonate; *K,* potassium; *Na,* sodium.
Adapted from Ignatavicius, D., Workman, M.L., Rebar, C., Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Elsevier. p. 1293.

16.7 mmol/L). Too rapid administration of IV fluids; use of the incorrect types of IV fluids, particularly hypotonic solutions; and correcting the blood glucose level too rapidly can lead to cerebral edema.

c. Treat hyperglycemia with insulin administered intravenously as prescribed.

d. Correct electrolyte imbalances (potassium level may be elevated as a result of dehydration and acidosis).

e. Monitor potassium level closely, because when the client receives treatment for the dehydration and acidosis, the serum potassium level will decrease and potassium replacement may be required.

f. Cardiac monitoring should be in place for the client with DKA due to risks associated with abnormal serum potassium levels.

4. Insulin IV administration

a. Use short-duration insulin only.

b. An IV bolus dose of short-duration regular U-100 insulin (usually 5 to 10 units) may be prescribed before a continuous infusion is begun.

c. The prescribed IV dose of insulin for continuous infusion is prepared in 0.9% or 0.45% NS as prescribed.

d. Always place the insulin infusion on an IV infusion controller.

e. Insulin is infused continuously until subcutaneous administration resumes, to prevent a rebound of the blood glucose level.

f. Monitor vital signs.

g. Monitor urinary output and monitor for signs of fluid overload.

h. Monitor potassium and glucose levels and for signs of increased intracranial pressure.

i. The potassium level will fall rapidly within the first hour of treatment as the dehydration and the acidosis are treated.

j. Potassium is administered intravenously in a diluted solution as prescribed; ensure adequate renal function before administering potassium.

5. Client education (Box 47.16)

Monitor the client being treated for DKA closely for signs of increased intracranial pressure. If the blood glucose level falls too far or too fast before the brain has time to equilibrate, water is pulled from the blood to the cerebrospinal fluid and the brain, causing cerebral edema and increased intracranial pressure.

C. Hyperosmolar hyperglycemic syndrome (HHS)

1. Description

a. Extreme hyperglycemia occurs without ketosis or acidosis.

b. The syndrome occurs most often in individuals with type 2 diabetes mellitus.

c. The major difference between HHS and DKA is that ketosis and acidosis do not occur with HHS; enough insulin is present with HHS to prevent the breakdown of fats for energy, **thus preventing ketosis.**

2. Assessment (see Table 47.3)

Telegram & Insta: NCLEX_RN_Edu

BOX 47.16 Client Education: Guidelines During Illness

- Take insulin or oral antidiabetic medications as prescribed.
- Determine the blood glucose level and test the urine for ketones every 3 to 4 hours.
- If the usual meal plan cannot be followed, substitute soft foods 6 to 8 times a day.
- If vomiting, diarrhea, or fever occurs, consume liquids every 30 to 60 minutes to prevent dehydration and to provide calories.
- Notify the primary health care provider if vomiting, diarrhea, or fever persists; if blood glucose levels are higher than 250 to 300 mg/dL (13.9 to 16.7 mmol/L); when ketonuria is present for more than 24 hours; when unable to take food or fluids for a period of 4 hours; or when illness persists for more than 2 days.

3. Interventions
   a. Treatment is similar to that for DKA.
   b. Treatment includes fluid replacement, correction of electrolyte imbalances, and insulin administration.
   c. Fluid replacement in the older client must be done very carefully because of the potential for heart failure.
   d. Insulin plays a less critical role in the treatment of HHS than it does in the treatment of DKA because ketosis and acidosis do not occur; rehydration alone may decrease glucose levels.

IX. Chronic Complications of Diabetes Mellitus

A. Diabetic retinopathy
   1. Description
      a. Chronic and progressive impairment of the retinal circulation that eventually causes hemorrhage
      b. Permanent vision changes and blindness can occur.
      c. The client has difficulty with carrying out the daily tasks of blood glucose testing and insulin injections.
   2. Assessment
      a. A change in vision is caused by the rupture of small microaneurysms in retinal blood vessels.
      b. Blurred vision results from macular edema.
      c. Sudden loss of vision results from retinal detachment.
      d. Cataracts result from lens opacity.
   3. Interventions
      a. Maintain safety.
      b. Early prevention via the control of hypertension and blood glucose levels
      c. Photocoagulation (laser therapy) may be done to remove hemorrhagic tissue to decrease scarring and prevent progression of the disease process.
      d. Vitrectomy may be done to remove vitreous hemorrhages and thus decrease tension on the retina, preventing detachment.
      e. Cataract removal with lens implantation improves vision.

B. Diabetic nephropathy
   1. Description: Progressive decrease in kidney function
   2. Assessment
      a. Microalbuminuria
      b. Thirst
      c. Fatigue
      d. Anemia
      e. Weight loss
      f. Signs of malnutrition
      g. Frequent urinary tract infections
      h. Signs of a neurogenic bladder
   3. Interventions
      a. Early prevention measures include the control of hypertension and blood glucose levels.
      b. Assess vital signs.
      c. Monitor intake and output.
      d. Monitor the blood urea nitrogen, creatinine, and urine albumin levels.
      e. Restrict dietary protein, sodium, and potassium intake as prescribed.
      f. Avoid nephrotoxic medications.
      g. Prepare the client for dialysis procedures if planned.
      h. Prepare the client for kidney transplant if planned.
      i. Prepare the client for pancreas transplant if planned.

C. Diabetic neuropathy
   1. Description
      a. General deterioration of the nervous system throughout the body
      b. Complications include the development of nonhealing ulcers of the feet, gastric paresis, and erectile dysfunction.
   2. Classifications
      a. Focal neuropathy or mononeuropathy: Involves a single nerve or group of nerves, most frequently cranial nerves III (oculomotor) and VI (abducens), resulting in diplopia
      b. Sensory or peripheral neuropathy: Affects distal portion of nerves, most frequently in the lower extremities
      c. Autonomic neuropathy: Symptoms vary according to the organ system involved.
      d. Cardiovascular: Cardiac denervation syndrome (heart rate does not respond to changes in oxygenation needs) and orthostatic hypotension occur.

Telegram & Insta: NCLEX_RN_Edu

e. Pupillary: Pupil does not dilate in response to decreased light.
f. Gastric: Decreased gastric emptying (gastroparesis)
g. Urinary: Neurogenic bladder
h. Skin: Decreased sweating
i. Adrenal: Hypoglycemic unawareness
j. Reproductive: Impotence, painful intercourse

3. Assessment: Findings depend on the classification
a. Paresthesias
b. Decreased or absent reflexes
c. Decreased sensation to vibration or light touch
d. Pain, aching, and burning in the lower extremities
e. Poor peripheral pulses
f. Skin breakdown and signs of infection
g. Weakness or loss of sensation in cranial nerves III (oculomotor), IV (trochlear), V (trigeminal), and VI (abducens)
h. Dizziness and postural hypotension
i. Nausea and vomiting
j. Diarrhea or constipation
k. Incontinence
l. Dyspareunia
m. Impotence
n. Hypoglycemic unawareness

4. Interventions
a. Early prevention measures include the control of hypertension and blood glucose levels.
b. Careful foot care is required to prevent trauma (Box 47.17).
c. Administer medications as prescribed for pain relief.
d. Initiate bladder training programs.
e. Instruct in the use of estrogen-containing lubricants for those with dyspareunia.
f. Prepare the client with impotence for penile injections or other possible treatment options as prescribed.
g. Cardiac complications: May include microvascular disease, hypertension, and hyperlipidemia (see Chapter 53)

BOX 47.17 Preventive Foot Care Instructions

- Provide meticulous skin care and proper foot care.
- Inspect feet daily and monitor feet for redness, swelling, or break in skin integrity.
- Notify the primary health care provider if redness or a break in the skin occurs.
- Avoid thermal injuries from hot water, heating pads, and baths.
- Wash feet with warm (not hot) water and dry thoroughly (avoid foot soaks).
- Avoid treating corns, blisters, or ingrown toenails.
- Do not cross legs or wear tight garments that may constrict blood flow.
- Apply moisturizing lotion to the feet but not between the toes.
- Prevent moisture from accumulating between the toes.
- Wear loose socks and well-fitting (not tight) shoes; do not go barefoot.
- Wear clean cotton socks to keep the feet warm and change the socks daily.
- Avoid wearing the same pair of shoes two days in a row.
- Avoid wearing open-toed shoes or shoes with a strap that goes between the toes.
- Check shoes for cracks or tears in the lining and for foreign objects before putting them on.
- Break in new shoes gradually.
- Cut toenails straight across and smooth nails with an emery board.
- Avoid smoking.
- Follow-up with podiatry referral and recommendations as needed.

X. Care of the Diabetic Client Undergoing Surgery

A. Preoperative care
1. Check with PHCP regarding withholding oral hypoglycemic medications or insulin.
2. Some long-acting oral antidiabetic medications are discontinued 24 to 48 hours before surgery.
3. Metformin may need to be discontinued 48 hours before surgery and may not be restarted until renal function is normal postoperatively.
4. All other oral antidiabetic medications are usually withheld on the day of surgery.
5. Insulin dose may be adjusted or withheld if IV insulin administration during surgery is planned.
6. Monitor blood glucose level.
7. Administer IV fluids as prescribed.

B. Postoperative care
1. Administer IV glucose and insulin infusions as prescribed until the client can tolerate oral feedings.
2. Administer supplemental short-acting insulin as prescribed based on blood glucose results.
3. Monitor blood glucose levels frequently, especially if the client is receiving parenteral nutrition.
4. When the client is tolerating food, ensure that the client receives an adequate amount of carbohydrates daily to prevent hypoglycemia.
5. Client is at higher risk for cardiovascular and renal complications postoperatively.
6. Client is also at risk for impaired wound healing.

PRACTICE QUESTIONS

1. A client is brought to the emergency department in an unresponsive state, and a diagnosis of hyperosmolar hyperglycemic syndrome is made. The nurse would **immediately** prepare to initiate which anticipated primary health care provider's prescription?
   1. Endotracheal intubation
   2. 100 units of NPH insulin
   3. Intravenous infusion of normal saline
   4. Intravenous infusion of sodium bicarbonate

2. An external insulin pump is prescribed for a client with diabetes mellitus. When the client asks the nurse about the functioning of the pump, the nurse bases the response on which information about the pump?
   1. It is timed to release programmed doses of either short-duration or NPH insulin into the bloodstream at specific intervals.
   2. It continuously infuses small amounts of NPH insulin into the bloodstream while regularly monitoring blood glucose levels.
   3. It is surgically attached to the pancreas and infuses regular insulin into the pancreas. This releases insulin into the bloodstream.
   4. It administers a small continuous dose of short-duration insulin subcutaneously. The client can self-administer an additional bolus dose from the pump before each meal.

3. A client with a diagnosis of diabetic ketoacidosis (DKA) is being treated in the emergency department. Which findings support this diagnosis? **Select all that apply.**
   - ❑ 1. Increase in pH
   - ❑ 2. Comatose state
   - ❑ 3. Deep, rapid breathing
   - ❑ 4. Decreased urine output
   - ❑ 5. Elevated blood glucose level

4. The nurse teaches a client with diabetes mellitus about differentiating between hypoglycemia and ketoacidosis. The client demonstrates an understanding of the teaching by stating that a form of glucose needs to be taken if which symptoms develop? **Select all that apply.**
   - ❑ 1. Polyuria
   - ❑ 2. Shakiness
   - ❑ 3. Palpitations
   - ❑ 4. Blurred vision
   - ❑ 5. Light-headedness
   - ❑ 6. Fruity breath odor

5. A client with diabetes mellitus demonstrates acute anxiety when admitted to the hospital for the treatment of hyperglycemia. What is the appropriate intervention to decrease the client's anxiety?
   1. Administer a sedative.
   2. Convey empathy, trust, and respect toward the client.
   3. Ignore the signs and symptoms of anxiety, anticipating that they will soon disappear.
   4. Make sure that the client is familiar with the correct medical terms to promote understanding of what is happening.

6. The nurse provides instructions to a client newly diagnosed with type 1 diabetes mellitus about measures to take if feeling sick to prevent diabetic ketoacidosis (DKA). The nurse recognizes accurate understanding of measures to prevent DKA when the client makes which statement?
   1. "I will stop taking my insulin if I'm too sick to eat."
   2. "I will decrease my insulin dose during times of illness."
   3. "I will adjust my insulin dose according to the level of glucose in my urine."
   4. "I will notify my primary health care provider (PHCP) if my blood glucose level is higher than 250 mg/dL (13.9 mmol/L)."

7. A client is admitted to a hospital with a diagnosis of diabetic ketoacidosis (DKA). The initial blood glucose level is 950 mg/dL (52.9 mmol/L). A continuous intravenous (IV) infusion of short-acting insulin is initiated, along with IV rehydration with normal saline. The serum glucose level is now decreased to 240 mg/dL (13.3 mmol/L). The nurse would **next** prepare to administer which medication?
   1. An ampule of 50% dextrose
   2. NPH insulin subcutaneously
   3. IV fluids containing dextrose
   4. Phenytoin for the prevention of seizures

8. The nurse is monitoring a client newly diagnosed with diabetes mellitus for signs of complications. Which sign or symptom, if frequently exhibited in the client, indicates that the client is at risk for chronic complications of diabetes if the blood glucose is not adequately managed?
   1. Polyuria
   2. Diaphoresis
   3. Pedal edema
   4. Decreased respiratory rate

Telegram & Insta: NCLEX_RN_Edu

9. The nurse is preparing a plan of care for a client with diabetes mellitus who has hyperglycemia. The nurse places **priority** on which client problem?
1. Lack of knowledge
2. Inadequate fluid volume
3. Compromised family coping
4. Inadequate consumption of nutrients

10. The home health nurse visits a client with a diagnosis of type 1 diabetes mellitus. The client reports a history of vomiting and diarrhea and tells the nurse that no food has been consumed for the last 24 hours. Which additional statement by the client indicates a **need for further teaching**?
1. "I need to stop my insulin."
2. "I need to increase my fluid intake."
3. "I need to monitor my blood glucose every 3 to 4 hours."
4. "I need to call my primary health care provider (PHCP) because of these symptoms."

11. The nurse is caring for a client after hypophysectomy and notes clear nasal drainage from the client's nostril. The nurse would take which **initial** action?
1. Lower the head of the bed.
2. Test the drainage for glucose.
3. Obtain a culture of the drainage.
4. Continue to observe the drainage.

12. The nurse is admitting a client who is diagnosed with syndrome of inappropriate antidiuretic hormone secretion (SIADH) and has serum sodium of 118 mEq/L (118 mmol/L). Which primary health care provider prescriptions would the nurse anticipate receiving? **Select all that apply.**
- ❑ 1. Initiate an infusion of 3% NaCl.
- ❑ 2. Administer intravenous furosemide.
- ❑ 3. Restrict fluids to 800 mL over 24 hours.
- ❑ 4. Elevate the head of the bed to high-Fowler's.
- ❑ 5. Administer a vasopressin antagonist as prescribed.

13. A client is admitted to an emergency department, and a diagnosis of myxedema coma is made. Which action would the nurse prepare to carry out **initially**?
1. Warm the client.
2. Maintain a patent airway.
3. Administer thyroid hormone.
4. Administer fluid replacement.

14. The nurse is caring for a client admitted to the emergency department with diabetic ketoacidosis (DKA). In the acute phase, the nurse plans for which **priority** intervention?
1. Correct the acidosis.
2. Administer 5% dextrose intravenously.
3. Apply a monitor for an electrocardiogram.
4. Administer short-duration insulin intravenously.

15. A client with type 1 diabetes mellitus who takes NPH daily in the morning calls the nurse to report recurrent episodes of hypoglycemia with exercising. Which statement by the client indicates an adequate understanding of the peak action of NPH insulin and exercise?
1. "I should not exercise since I am taking insulin."
2. "The best time for me to exercise is after breakfast."
3. "The best time for me to exercise is mid- to late afternoon."
4. "NPH is a basal insulin, so I should exercise in the evening."

16. The nurse is completing an assessment on a client who is being admitted for a diagnostic workup for primary hyperparathyroidism. Which client complaints would be characteristic of this disorder? **Select all that apply.**
- ❑ 1. Polyuria
- ❑ 2. Headache
- ❑ 3. Bone pain
- ❑ 4. Nervousness
- ❑ 5. Weight gain

17. The nurse is teaching a client with hyperparathyroidism how to manage the condition at home. Which response by the client indicates the **need for additional teaching**?
1. "I should consume less than 1 liter of fluid per day."
2. "I should use my treadmill or go for walks daily."
3. "I should follow a moderate-calcium, high-fiber diet."
4. "My alendronate helps keep calcium from coming out of my bones."

18. A client with a diagnosis of addisonian crisis is being admitted to the intensive care unit. Which findings will the interprofessional health care team focus on? **Select all that apply.**
- ❑ 1. Hypotension
- ❑ 2. Leukocytosis
- ❑ 3. Hyperkalemia
- ❑ 4. Hypercalcemia
- ❑ 5. Hypernatremia

19. The nurse is monitoring a client who was diagnosed with type 1 diabetes mellitus and is being treated with NPH and regular insulin. Which manifestations would alert the nurse to the presence of a possible hypoglycemic reaction? **Select all that apply.**
- ❑ 1. Tremors
- ❑ 2. Anorexia
- ❑ 3. Irritability
- ❑ 4. Nervousness
- ❑ 5. Hot, dry skin
- ❑ 6. Muscle cramps

Telegram & Insta: NCLEX_RN_Edu

20. The nurse is performing an assessment on a client with pheochromocytoma. Which assessment data would indicate a potential complication associated with this disorder?
1. A urinary output of 50 mL/hr
2. A coagulation time of 5 minutes
3. A heart rate that is 90 beats per minute and irregular
4. A blood urea nitrogen level of 20 mg/dL (7.1 mmol/L)

21. The nurse is monitoring a client diagnosed with acromegaly who was treated with transsphenoidal hypophysectomy and is recovering in the intensive care unit. Which findings would alert the nurse to the presence of a possible postoperative complication? **Select all that apply.**
- ❑ 1. Anxiety
- ❑ 2. Leukocytosis
- ❑ 3. Chvostek's sign
- ❑ 4. Urinary output of 800 mL/hr
- ❑ 5. Clear drainage on nasal dripper pad

22. The nurse performs a physical assessment on a client with type 2 diabetes mellitus. Findings include a fasting blood glucose level of 70 mg/dL (3.9 mmol/L), temperature of 101° F (38.3° C), pulse of 82 beats per minute, respirations of 20 breaths per minute, and blood pressure of 118/68 mm Hg. Which finding would be the **priority** concern to the nurse?
1. Pulse
2. Respiration
3. Temperature
4. Blood pressure

23. The nurse is preparing a client with a new diagnosis of hypothyroidism for discharge. The nurse determines that the client understands discharge instructions if the client states that which signs and symptoms are associated with this diagnosis? **Select all that apply.**
- ❑ 1. Tremors
- ❑ 2. Weight loss
- ❑ 3. Feeling cold
- ❑ 4. Loss of body hair
- ❑ 5. Persistent lethargy
- ❑ 6. Puffiness of the face

24. A client has just been admitted to the nursing unit following thyroidectomy. Which assessment is the **priority** for this client?
1. Hoarseness
2. Hypocalcemia
3. Audible stridor
4. Edema at the surgical site

25. A client has been diagnosed with hyperthyroidism. The nurse monitors for which signs and symptoms indicating a complication of this disorder? **Select all that apply.**
- ❑ 1. Fever
- ❑ 2. Nausea
- ❑ 3. Lethargy
- ❑ 4. Tremors
- ❑ 5. Confusion
- ❑ 6. Bradycardia

ANSWERS

1. *Answer:* 3

Rationale: The primary goal of treatment in hyperosmolar hyperglycemic syndrome (HHS) is to rehydrate the client to restore fluid volume and to correct electrolyte deficiency. Intravenous (IV) fluid replacement is similar to that administered in diabetic ketoacidosis (DKA) and begins with IV infusion of normal saline. Regular insulin, not NPH insulin, would be administered. The use of sodium bicarbonate to correct acidosis is avoided because it can precipitate a further drop in serum potassium levels. Intubation and mechanical ventilation are not required to treat HHS.

Test-Taking Strategy: Focus on the subject, treatment of HHS, and note the strategic word, *immediately*. If you can recall the treatment for DKA, you will be able to answer this question easily. Treatment for HHS is similar to the treatment for DKA and begins with rehydration.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1133.

2. *Answer:* 4

Rationale: An insulin pump provides a small continuous dose of short-duration (rapid- or short-acting) insulin subcutaneously throughout the day and night. The client can self-administer an additional bolus dose from the pump before each meal as needed. Short-duration insulin is used in an insulin pump. An external pump is not attached surgically to the pancreas.

Test-Taking Strategy: Focus on the subject, use of an insulin pump. Recalling that short-duration insulin is used in an insulin pump will assist in eliminating options 1 and 2. Noting the word *external* in the question will assist in eliminating option 3.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1116-1117.

Telegram & Insta: NCLEX_RN_Edu

3. *Answer:* 2, 3, 5
Rationale: Because of the profound deficiency of insulin associated with DKA, glucose cannot be used for energy and the body breaks down fat as a secondary source of energy. Ketones, which are acid by-products of fat metabolism, build up, and the client experiences a metabolic ketoacidosis. High serum glucose contributes to an osmotic diuresis and the client becomes severely dehydrated. If untreated, the client will become comatose due to severe dehydration, acidosis, and electrolyte imbalance. Kussmaul's respirations, the deep rapid breathing associated with DKA, is a compensatory mechanism by the body. The body attempts to correct the acidotic state by blowing off carbon dioxide (CO_2), which is an acid. In the absence of insulin, the client will experience severe hyperglycemia. Option 1 is incorrect, because in acidosis the pH would be low. Option 4 is incorrect because a high serum glucose will result in an osmotic diuresis and the client will experience polyuria.
Test-Taking Strategy: Focus on the **subject,** findings associated with DKA. Recall that the pathophysiology of DKA is the breakdown of fats for energy. The breakdown of fats leads to a state of acidosis. The high serum glucose contributes to an osmotic diuresis. Knowing the pathophysiology of DKA will aid in identification of the correct answers.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1130-1132; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 406, 408.

4. *Answer:* 2, 3, 5
Rationale: Shakiness, palpitations, and light-headedness are signs/symptoms of hypoglycemia and would indicate the need for food or glucose. Polyuria, blurred vision, and a fruity breath odor are manifestations of hyperglycemia.
Test-Taking Strategy: Focus on the **subject,** the treatment of hypoglycemia. Think about its pathophysiology and the manifestations that occur. Recalling the signs and symptoms of hypoglycemia will direct you to the correct option.
References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1290.

5. *Answer:* 2
Rationale: Anxiety is a subjective feeling of apprehension, uneasiness, or dread. The appropriate intervention is to address the client's feelings related to the anxiety. Administering a sedative is not the most appropriate intervention and does not address the source of the client's anxiety. The nurse should not ignore the client's anxious feelings. Anxiety needs to be managed before meaningful client education can occur.
Test-Taking Strategy: Use **therapeutic communication techniques** to answer the question. Remember that the client's feelings are the priority. Keeping this in mind will direct you easily to the correct option.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 50, 1129-1130; Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Mosby. pp. 333-335.

6. *Answer:* 4
Rationale: During illness, the client with type 1 diabetes mellitus is at increased risk of diabetic ketoacidosis, due to hyperglycemia associated with the stress response and due to a typically decreased caloric intake. As part of sick day management, the client with diabetes should monitor blood glucose levels and should notify the PHCP if the level is higher than 250 mg/dL (13.9 mmol/L). Insulin should never be stopped. In fact, insulin may need to be increased during times of illness. Doses should not be adjusted without the PHCP's advice and are usually adjusted on the basis of blood glucose levels, not urinary glucose readings.
Test-Taking Strategy: Use general medication guidelines to answer the question. Note that options 1, 2, and 3 are **comparable or alike** and all relate to adjustment of insulin doses.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1132; Pagana, K., Pagana, T., & Pagana, T. N. (2021). *Mosby's diagnostic and laboratory test reference.* (15th ed.). St. Louis: Elsevier. pp. 464-465.

7. *Answer:* 3
Rationale: Emergency management of DKA focuses on correcting fluid and electrolyte imbalances and normalizing the serum glucose level. If the corrections occur too quickly, serious consequences, including hypoglycemia and cerebral edema, can occur. During management of DKA, when the blood glucose level falls to 250 to 300 mg/dL (13.9 to 16.7 mmol/L), the IV infusion rate is reduced and a dextrose solution is added to maintain a blood glucose level of about 250 mg/dL (13.9 mmol/L), or until the client recovers from ketosis. Fifty percent dextrose is used to treat hypoglycemia. NPH insulin is not used to treat DKA. Phenytoin is not a usual treatment measure for DKA.
Test-Taking Strategy: Note the **strategic word,** *next.* Focus on the **subject,** management of DKA. Eliminate option 2 first, knowing that short-duration (rapid-acting) insulin is used in the management of DKA. Eliminate option 1 next, knowing that this is the treatment for hypoglycemia. Note the words *the serum glucose level is now decreased to 240 mg/dL (13.3 mmol/L).* This should indicate that the IV solution containing dextrose is the next step in the management of care.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 408.

8. *Answer:* 1
Rationale: Chronic hyperglycemia, resulting from poor glycemic control, contributes to the microvascular and macrovascular complications of diabetes mellitus. Classic symptoms of hyperglycemia include polydipsia, polyuria, and polyphagia. Diaphoresis may occur in hypoglycemia. Hypoglycemia is an acute complication of diabetes mellitus; however, it does not predispose a client to the chronic complications of diabetes mellitus. Therefore, option 2 can be eliminated because this finding is characteristic of hypoglycemia. Options 3 and 4 are not associated with diabetes mellitus.
Test-Taking Strategy: Focus on the **subject,** chronic complications of diabetes mellitus. Recall that poor glycemic control

Telegram & Insta: NCLEX_RN_Edu

contributes to development of the chronic complications of diabetes mellitus. Remember the 3 Ps associated with hyperglycemia—polyuria, polydipsia, and polyphagia.
References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1268; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1110.

9. *Answer:* 2
Rationale: An increased blood glucose level will cause the kidneys to excrete the glucose in the urine. This glucose is accompanied by fluids and electrolytes, causing an osmotic diuresis leading to dehydration. This fluid loss must be replaced when it becomes severe. Options 1, 3, and 4 are not related specifically to the information in the question.
Test-Taking Strategy: Note the **strategic word,** *priority*, and focus on the **information in the question.** Use **Maslow's Hierarchy of Needs theory**. The correct option indicates a physiological need and is the priority. Options 1, 3, and 4 are problems that may need to be addressed after providing for the priority physiological needs.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1133; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 406.

10. *Answer:* 1
Rationale: When a client with diabetes mellitus is unable to eat normally because of illness, the client still should take the prescribed insulin or oral medication. The client should consume additional fluids and should notify the PHCP. The client should monitor the blood glucose level every 3 to 4 hours. The client should also monitor the urine for ketones during illness.
Test-Taking Strategy: Note the **strategic words,** *need for further teaching*. These words indicate a **negative event query** and the need to select the incorrect statement. Remembering that the client needs to take insulin will direct you easily to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1294.

11. *Answer:* 2
Rationale: After hypophysectomy, the client should be monitored for rhinorrhea, which could indicate a cerebrospinal fluid leak. If this occurs, the drainage should be collected and tested for the presence of cerebrospinal fluid. Cerebrospinal fluid contains glucose, and if positive, this would indicate that the drainage is cerebrospinal fluid. The head of the bed should remain elevated to prevent increased intracranial pressure. Clear nasal drainage would not indicate the need for a culture. Continuing to observe the drainage without taking action could result in a serious complication.
Test-Taking Strategy: Note the **strategic word,** *initial*. Note that an action is required. Option 1 can be eliminated first by recalling that this action can increase intracranial pressure. Option 3 can be eliminated also, because the drainage is clear. Because an action is required, eliminate option 4.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 321.

12. *Answer:* 1, 3, 5
Rationale: Clients with SIADH experience excess secretion of antidiuretic hormone (ADH), which leads to excess intravascular volume, a declining serum osmolarity, and dilutional hyponatremia. Management is directed at correcting the hyponatremia and preventing cerebral edema. Hypertonic saline is prescribed when the hyponatremia is severe, less than 120 mEq/L (120 mmol/L). An intravenous (IV) infusion of 3% saline is hypertonic. Hypertonic saline must be infused slowly as prescribed, and an infusion pump must be used. Fluid restriction is a useful strategy aimed at correcting dilutional hyponatremia. Vasopressin is an ADH; vasopressin antagonists are used to treat SIADH. Furosemide may be used to treat extravascular volume and dilutional hyponatremia in SIADH, but it is only safe to use if the serum sodium is at least 125 mEq/L (125 mmol/L). When furosemide is used, potassium supplementation should also occur and serum potassium levels should be monitored. To promote venous return, the head of the bed should not be raised more than 10 degrees for the client with SIADH. Maximizing venous return helps avoid stimulating stretch receptors in the heart that signal to the pituitary that more ADH is needed.
Test-Taking Strategy: Focus on the **subject,** treatment for SIADH. Think about the pathophysiology associated with SIADH. Remember that SIADH is associated with the increased secretion of ADH, or vasopressin. Excess vasopressin leads to increased intravascular fluid volume, decreased serum osmolality, and hyponatremia. When hyponatremia and decreased serum osmolality become severe, cerebral edema occurs.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 419, 422.

13. *Answer:* 2
Rationale: Myxedema coma is a rare but serious disorder that results from persistently low thyroid production. Coma can be precipitated by acute illness, rapid withdrawal of thyroid medication, anesthesia and surgery, hypothermia, and the use of sedatives and opioid analgesics. In myxedema coma, the initial nursing action is to maintain a patent airway. Oxygen needs to be administered, followed by fluid replacement, keeping the client warm, monitoring vital signs, and administering thyroid hormones by the intravenous route.
Test-Taking Strategy: Note the **strategic word,** *initially*. All the options are appropriate interventions, but use the **ABCs—airway, breathing, and circulation**—in selecting the correct option.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 426-427.

Telegram & Insta: NCLEX_RN_Edu

14. *Answer:* 4

Rationale: Lack of insulin (absolute or relative) is the primary cause of DKA. Treatment consists of insulin administration (short- or rapid-acting), intravenous fluid administration (normal saline initially, not 5% dextrose), and potassium replacement, followed by correcting acidosis. Cardiac monitoring is important due to alterations in potassium levels associated with DKA and its treatment, but applying an electrocardiogram monitor is not the priority action.

Test-Taking Strategy: Focus on the client's diagnosis. Note the **strategic word,** *priority*. Remember that in DKA, the initial treatment is short- or rapid-acting insulin. Normal saline is administered initially; therefore, option 2 is incorrect. Options 1 and 3 may be components of the treatment plan but are not the priority.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1133-1132.

15. *Answer:* 2

Rationale: Exercise is an important part of diabetes management. It promotes weight loss, decreases insulin resistance, and helps control blood glucose levels. A hypoglycemic reaction may occur in response to increased exercise, so clients should exercise either an hour after mealtime or after consuming a 10- to 15-g carbohydrate snack, and they should check their blood glucose level before exercising. Option 1 is incorrect because clients with diabetes should exercise, though they should check with their primary health care provider before starting a new exercise program. Option 3 is incorrect; clients should avoid exercise during the peak time of insulin. NPH insulin peaks at 4 to 12 hours; therefore, afternoon exercise takes place during the peak of the medication. Option 4 is incorrect; NPH insulin is an intermediate-acting insulin, not a basal insulin.

Test-Taking Strategy: Focus on the **subject,** peak action of NPH insulin. Recalling that NPH insulin peaks at 4 to 12 hours and that exercise is beneficial for clients with diabetes will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1122-1123.

16. *Answer:* 1, 3

Rationale: The role of parathyroid hormone (PTH) in the body is to maintain serum calcium homeostasis. In hyperparathyroidism, PTH levels are high, which causes bone resorption (calcium is pulled from the bones). Hypercalcemia occurs with hyperparathyroidism. Elevated serum calcium levels produce osmotic diuresis and thus polyuria. This diuresis leads to dehydration (weight loss rather than weight gain). Loss of calcium from the bones causes bone pain. Options 2, 4, and 5 are not associated with hyperparathyroidism. Some gastrointestinal symptoms include anorexia, nausea, vomiting, and constipation.

Test-Taking Strategy: Focus on the **subject,** assessment findings in hyperparathyroidism. Think about the pathophysiology associated with hyperparathyroidism. Remember that hypercalcemia is associated with this disorder, that hypercalcemia leads to diuresis, and that calcium loss from bone leads to bone pain.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1262-1263.

17. *Answer:* 1

Rationale: In hyperparathyroidism, clients experience excess parathyroid hormone (PTH) secretion. A role of PTH in the body is to maintain serum calcium homeostasis. When PTH levels are high, there is excess bone resorption (calcium is pulled from the bones). In clients with elevated serum calcium levels, there is a risk of nephrolithiasis. One to two liters of fluids daily should be encouraged to protect the kidneys and decrease the risk of nephrolithiasis. Moderate physical activity, particularly weight-bearing activity, minimizes bone resorption and helps protect against pathological fracture. Walking, as an exercise, should be encouraged in the client with hyperparathyroidism. Even though serum calcium is already high, clients should follow a moderate-calcium diet, because a low-calcium diet will surge PTH. Calcium causes constipation, so a diet high in fiber is recommended. Alendronate is a bisphosphate that inhibits bone resorption. In bone resorption, bone is broken down and calcium is deposited into the serum.

Test-Taking Strategy: Note the **strategic words,** *need for additional teaching*. These words indicate a **negative event query** and the need to select the incorrect statement. Consider the pathophysiology of hyperparathyroidism. Hyperparathyroidism leads to bone demineralization, which places the client at risk for pathological fracture, and high serum calcium, which places the client at risk for nephrolithiasis. Knowing that fluids should be encouraged rather than limited to help prevent nephrolithiasis should direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1159-1160.

18. *Answer:* 1, 3

Rationale: In Addison's disease, also known as adrenal insufficiency, destruction of the adrenal gland leads to decreased production of adrenocortical hormones, including the glucocorticoid cortisol and the mineralocorticoid aldosterone. Addisonian crisis, also known as *acute adrenal insufficiency,* occurs when there is extreme physical or emotional stress and lack of sufficient adrenocortical hormones to manage the stressor. Addisonian crisis is a life-threatening emergency. One of the roles of endogenous cortisol is to enhance vascular tone and vascular response to the catecholamines epinephrine and norepinephrine. Hypotension occurs when vascular tone is decreased and blood vessels cannot respond to epinephrine and norepinephrine. The role of aldosterone in the body is to support the blood pressure by holding salt and water and excreting potassium. When there is insufficient aldosterone, salt and water are lost and potassium builds up; this leads to hypotension from decreased vascular volume, hyponatremia, and hyperkalemia. The remaining options are not associated with addisonian crisis.

Test-Taking Strategy: Focus on the **subject,** addisonian crisis. Think about the pathophysiology associated with Addison's disease. Recalling that in Addison's disease there is a decrease

Telegram & Insta: NCLEX_RN_Edu

in the glucocorticoid cortisol and the mineralocorticoid aldosterone will assist in determining the correct answer.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1238-1239.

19. *Answer:* 1, 3, 4
Rationale: Decreased blood glucose levels produce autonomic nervous system symptoms, which are manifested classically as nervousness, irritability, and tremors. Option 5 is more likely to occur with hyperglycemia. Options 2 and 6 are unrelated to the manifestations of hypoglycemia. In hypoglycemia, usually the client feels hunger.
Test-Taking Strategy: Focus on the **subject,** a hypoglycemic reaction. Think about the pathophysiology and manifestations that occur when the blood glucose is low. Recalling the signs of this type of reaction will direct you easily to the correct options.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 410-411.

20. *Answer:* 3
Rationale: Pheochromocytoma is a catecholamine-producing tumor usually found in the adrenal medulla, but extra-adrenal locations include the chest, bladder, abdomen, and brain; it is typically a benign tumor but can be malignant. Excessive amounts of epinephrine and norepinephrine are secreted. The complications associated with pheochromocytoma include hypertensive retinopathy and nephropathy, myocarditis, increased platelet aggregation, and stroke. Death can occur from shock, stroke, kidney failure, dysrhythmias, or dissecting aortic aneurysm. An irregular heart rate indicates the presence of a dysrhythmia. A coagulation time of 5 minutes is normal. A urinary output of 50 mL/hr is an adequate output. A blood urea nitrogen level of 20 mg/dL (7.1 mmol/L) is a normal finding.
Test-Taking Strategy: Use the **ABCs—airway, breathing, and circulation.** An irregular heart rate is associated with circulation. In addition, knowing the normal hourly expectations associated with urinary output and the normal laboratory values for coagulation time and blood urea nitrogen level assists in selection of the correct option.
References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 699; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1168-1169.

21. *Answer:* 2, 4, 5
Rationale: Acromegaly results from excess secretion of growth hormone, usually caused by a benign tumor on the anterior pituitary gland. Treatment is surgical removal of the tumor, usually with a sublabial transsphenoidal complete or partial hypophysectomy. The sublabial transsphenoidal approach is often through an incision in the inner upper lip at the gum line. Transsphenoidal surgery is a type of brain surgery, and infection is a primary concern. Leukocytosis, or an elevated white count, may indicate infection. Diabetes insipidus is a possible complication of transsphenoidal hypophysectomy. In diabetes insipidus there is decreased secretion of antidiuretic hormone, and clients excrete large amounts of dilute urine. Following transsphenoidal surgery, the nasal passages are packed and a dripper pad is secured under the nares. Clear drainage on the dripper pad is suggestive of a cerebrospinal fluid leak. The surgeon needs to be notified and the drainage needs to be tested for glucose. A cerebrospinal fluid leak increases the postoperative risk of meningitis. Anxiety is a nonspecific finding that is common to many disorders. Chvostek's sign is a test of nerve hyperexcitability associated with hypocalcemia and is seen as grimacing in response to tapping on the facial nerve. Chvostek's sign has no association with complications of sublabial transsphenoidal hypophysectomy.
Test-Taking Strategy: Focus on the **subject,** postoperative complications of sublabial transsphenoidal hypophysectomy. Knowing that infection, diabetes insipidus, and cerebrospinal fluid leak are possible complications will assist in determining the correct answer.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1234.

22. *Answer:* 3
Rationale: In the client with type 2 diabetes mellitus, an elevated temperature may indicate infection. Infection is a leading cause of hyperosmolar hyperglycemic syndrome in the client with type 2 diabetes mellitus. The other findings are within normal limits.
Test-Taking Strategy: Note the **strategic word,** *priority.* Use knowledge of the normal values of vital signs to direct you to the correct option. The client's temperature is the only abnormal value. Remember that an elevated temperature can indicate an infectious process that can lead to complications in the client with diabetes mellitus.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1132, 1139.

23. *Answer:* 3, 4, 5, 6
Rationale: Feeling cold, hair loss, lethargy, and facial puffiness are signs of hypothyroidism. Tremors and weight loss are signs of hyperthyroidism.
Test-Taking Strategy: Focus on the **subject,** signs and symptoms associated with hypothyroidism. Options 1 and 2 can be eliminated if you remember that in *hypo*thyroidism there is an *under*secretion of thyroid hormone that causes the metabolism to *slow* down.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1155-1156; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 427.

Telegram & Insta: NCLEX_RN_Edu

24. *Answer:* 3

Rationale: Thyroidectomy is the removal of the thyroid gland, which is located in the anterior neck. It is very important to monitor airway status, as any swelling to the surgical site could cause respiratory distress. Although all of the options are important for the nurse to monitor, the priority nursing action is to monitor the airway.

Test-Taking Strategy: Note the **strategic word,** *priority*. Use the **ABCs—airway, breathing, and circulation**—to assist in directing you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1154.

25. *Answer:* 1, 2, 4, 5

Rationale: Thyroid storm is an acute and life-threatening complication that occurs in a client with uncontrollable hyperthyroidism. Signs and symptoms of thyroid storm include elevated temperature (fever), nausea, and tremors. In addition, as the condition progresses, the client becomes confused. The client is restless and anxious and experiences tachycardia.

Test-Taking Strategy: Focus on the **subject,** signs and symptoms indicating a complication of hyperthyroidism. Recall that thyroid storm is a complication of hyperthyroidism. Options 3 and 6 can be eliminated if you remember that thyroid storm is caused by the release of thyroid hormones into the bloodstream, causing uncontrollable *hyper*thyroidism. Lethargy and bradycardia (think: slow down) are signs of *hypo*thyroidism (slow metabolism).

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1151, 1155; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 427.

CHAPTER 48

Endocrine Medications

Contributors: David Petersen, MSN-Ed, RN
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS **Glucose Regulation; Hormonal Regulation**

I. Pituitary Medications

A. Description
- **1.** The anterior pituitary gland secretes growth hormone (GH), thyroid-stimulating hormone (TSH), adrenocorticotropic hormone (ACTH), prolactin, melanocyte-stimulating hormone (MSH), and gonadotropins (follicle-stimulating hormone [FSH] and luteinizing hormone [LH]).
- **2.** The posterior pituitary gland secretes antidiuretic hormone (vasopressin) and oxytocin.

B. Growth hormones and related medications (Box 48.1)
- **1.** Uses
  - **a.** Growth hormones are used to treat pediatric or adult growth hormone deficiency.
  - **b.** Growth hormone receptor antagonists are used to treat acromegaly.
  - **c.** Growth hormone–releasing factor is used to evaluate anterior pituitary function.
- **2.** Side and adverse effects
  - **a.** May vary depending on the medication formula
  - **b.** Development of antibodies to growth hormone
  - **c.** Headache, muscle pain, weakness, vertigo
  - **d.** Diarrhea, nausea, abdominal discomfort
  - **e.** Mild hyperglycemia
  - **f.** Hypertension
  - **g.** Weight gain
  - **h.** Allergic reaction (rash, swelling), pain at injection site
  - **i.** Elevated aspartate aminotransferase (AST) and alanine aminotransferase (ALT)
- **3.** Interventions
  - **a.** Assess the child's physical growth, and compare growth with standards.
  - **b.** Recommend annual bone age determinations for children receiving growth hormones.
  - **c.** Monitor vital signs, blood glucose levels, AST and ALT levels, and thyroid function tests.
  - **d.** Teach the client and family about the clinical manifestations of hyperglycemia, other side and adverse effects of therapy, and the importance of follow-up regarding periodic blood tests.

II. Antidiuretic Hormones

A. Desmopressin acetate; vasopressin

B. Description
- **1.** Antidiuretic hormones enhance reabsorption of water in the kidneys, promoting an antidiuretic effect and regulating fluid balance.
- **2.** Antidiuretic hormones are used in diabetes insipidus.
- **3.** Vasopressin is used less commonly than desmopressin acetate to treat diabetes insipidus; vasopressin is commonly used to treat shock.

C. Side and adverse effects
- **1.** Flushing
- **2.** Headache
- **3.** Nausea and abdominal cramps
- **4.** Water intoxication
- **5.** Hypertension with water intoxication
- **6.** Nasal congestion with nasal administration

D. Interventions
- **1.** Monitor weight.
- **2.** Monitor intake and output and urine osmolality.
- **3.** Monitor electrolyte levels.
- **4.** Monitor for signs of dehydration, indicating the need to increase the dosage.
- **5.** Monitor for signs of water intoxication (drowsiness, listlessness, shortness of breath, and headache), indicating the need to decrease dosage.
- **6.** Monitor blood pressure.
- **7.** Instruct clients in how to use the intranasal medication.

Telegram & Insta: NCLEX_RN_Edu

BOX 48.1 Growth Hormones and Related Medications

Growth Hormones
- Somatropin
- Mecasermin

Growth Hormone Receptor Antagonists
- Octreotide acetate
- Lanreotide
- Pasireotide
- Pegvisomant

BOX 48.2 Thyroid Hormones
- Levothyroxine sodium
- Liothyronine sodium
- Thyroid, desiccated

BOX 48.3 Antithyroid Medications and Thyroid Eye Disease

Antithyroid Medications
- Methimazole
- Propylthiouracil
- Potassium iodide and strong iodine solution
- Sodium iodide

Thyroid Eye Disease
- Teprotumumab: reduces eye swelling, bulging, and double vision

8. Instruct clients to check their weight daily to identify weight gain.
9. Instruct clients to report signs of water intoxication or symptoms of headache or shortness of breath.

III. Thyroid Hormones (Box 48.2)

A. Description
1. Thyroid hormones control the metabolic rate of tissues and accelerate heat production and oxygen consumption.
2. Thyroid hormones are used to replace the thyroid hormone deficit in conditions such as **hypothyroidism** and **myxedema coma.**
3. Thyroid hormones enhance the action of oral anticoagulants, sympathomimetics, and antidepressants and decrease the action of insulin, oral hypoglycemics, and digitalis preparations; the action of thyroid hormones is decreased by phenytoin and carbamazepine.
4. Thyroid hormones should be given at least 4 hours apart from multivitamins, aluminum hydroxide and magnesium hydroxide, simethicone, calcium carbonate, phosphate binders, bile acid sequestrants, iron, and sucralfate, because these medications decrease the absorption of thyroid replacements.

B. Side and adverse effects
1. Nausea and decreased appetite
2. Abdominal cramps and diarrhea
3. Weight loss
4. Nervousness and tremors
5. Insomnia
6. Sweating
7. Heat intolerance
8. Tachycardia, dysrhythmias, palpitations, chest pain
9. Hypertension
10. Headache
11. Toxicity: **Hyperthyroidism**

C. Interventions
1. Assess the client for a history of medications currently being taken.
2. Monitor vital signs.
3. Monitor weight.
4. Monitor triiodothyronine (T3), thyroxine (T4), and TSH levels.
5. Instruct the client to take the medication at the same time each day, in the morning without food.
6. Instruct the client on how to monitor the pulse rate.
7. Inform the client that it is important to discuss which foods to specifically avoid that may inhibit thyroid secretion based on the client's individualized diet plan and medication regimen.
8. Advise the client to avoid over-the-counter medications.
9. Instruct the client to wear a MedicAlert bracelet.

Advise the client taking a thyroid hormone to report symptoms of hyperthyroidism, such as a fast heartbeat (tachycardia), chest pain, palpitations, or excessive sweating. These indicate signs of toxicity.

IV. Antithyroid Medications (Box 48.3)

A. Description
1. Antithyroid medications inhibit the synthesis of thyroid hormone.
2. Antithyroid medications are used for hyperthyroidism and Graves' disease.

B. Side and adverse effects
1. Nausea and vomiting
2. Diarrhea
3. Drowsiness, headache, fever
4. Hypersensitivity with rash
5. Agranulocytosis with leukopenia and thrombocytopenia
6. Alopecia and hyperpigmentation
7. Toxicity: Hypothyroidism
8. Iodism: Characterized by vomiting, abdominal pain, metallic or brassy taste in the mouth, rash, and sore gums and salivary glands

Telegram & Insta: NCLEX_RN_Edu

Iodism is a concern for clients taking strong iodine solution, also known as Lugol's solution. Because of the risk of iodism, the use of strong iodine solution is limited to about 2 weeks; it is generally used for clients with hyperthyroidism in preparation for thyroid surgery.

C. Interventions

1. Monitor vital signs.
2. Monitor triiodothyronine, thyroxine, and TSH levels.
3. Monitor weight.
4. Instruct the client to take medication with meals to avoid gastrointestinal (GI) upset.
5. Instruct the client in how to monitor the pulse rate.
6. Inform the client of side and adverse effects and when to notify the primary health care provider (PHCP).
7. Instruct the client in the signs of hypothyroidism.
8. Instruct the client regarding the importance of medication compliance and that abruptly stopping the medication could cause **thyroid storm.**
9. Instruct the client to monitor for signs and symptoms of thyroid storm (fever, flushed skin, confusion and behavioral changes, tachycardia, dysrhythmias, and signs of heart failure).
10. Instruct the client to monitor for signs of iodism.
11. Advise the client to consult the PHCP before eating iodized salt and iodine-rich foods.
12. Instruct the client to avoid acetylsalicylic acid and medications containing iodine.

Methimazole causes agranulocytosis. Therefore, advise the client to contact the PHCP if a fever or sore throat develops.

V. Parathyroid Medications (Box 48.4)

A. Description

1. Parathyroid hormone regulates serum calcium levels.
2. Low serum levels of calcium stimulate parathyroid hormone release.
3. Hyperparathyroidism results in a high serum calcium level and bone demineralization; medication is used to lower the serum calcium level.
4. Hypoparathyroidism results in a low serum calcium level, which increases neuromuscular excitability; treatment includes calcium and vitamin D supplements.
5. Calcium salts administered with digoxin increase the risk of digoxin toxicity.
6. Oral calcium salts reduce the absorption of tetracycline hydrochloride.

B. Interventions

1. Monitor electrolyte and calcium levels.
2. Assess for signs and symptoms of hypocalcemia and hypercalcemia.

BOX 48.4 Medications to Treat Calcium Disorders

Oral Calcium Supplements

- Calcium acetate
- Calcium carbonate
- Calcium citrate
- Calcium glubionate
- Calcium gluconate
- Tribasic calcium phosphate

Vitamin D Supplements

- Cholecalciferol (vitamin D_3)
- Ergocalciferol (vitamin D_2)

Bisphosphonates and Calcium Regulators

- Alendronate sodium
- Calcitonin salmon
- Etidronate disodium
- Ibandronate
- Pamidronate disodium
- Risedronate sodium
- Zoledronic acid

Medications to Treat Hypercalcemia

- Cinacalcet hydrochloride
- Doxercalciferol
- Calcitonin
- Paricalcitol

3. Assess for symptoms of tetany in the client with hypocalcemia.
4. Assess for renal calculi, polyuria, polydipsia, anorexia, nausea, or constipation in the client with hypercalcemia.
5. Instruct the client in the signs and symptoms of hypercalcemia and hypocalcemia.
6. Instruct the client to check over-the-counter medication labels for the possibility of calcium content.
7. Instruct the client receiving oral calcium supplements to maintain an adequate intake of vitamin D, because vitamin D enhances the absorption of calcium.
8. Instruct the client receiving calcium regulators such as alendronate sodium to swallow the tablet whole with water at least 30 minutes before breakfast and not to lie down for at least 30 minutes.
9. Instruct the client using nasal spray of calcitonin to alternate nares.
10. Instruct the client using antihypercalcemic agents to decrease or avoid foods rich in calcium such as green, leafy vegetables; dairy products; shellfish; and soy.
11. Instruct the client not to take other medications within 1 hour of taking a calcium supplement.
12. Instruct the client to increase fluid and fiber in the diet to prevent constipation associated with calcium supplements.

Telegram & Insta: NCLEX_RN_Edu

VI. Corticosteroids: Mineralocorticoids

A. Fludrocortisone acetate

B. Description

1. Mineralocorticoids are steroid hormones that enhance the reabsorption of sodium and chloride and promote the excretion of potassium and hydrogen from the renal tubules, thereby helping maintain fluid and electrolyte balance.
2. Mineralocorticoids are used for replacement therapy in primary and secondary adrenal insufficiency in **Addison's disease.**

C. Side and adverse effects

1. Sodium and water retention, edema, hypertension
2. Hypokalemia
3. Hypocalcemia
4. Osteoporosis, compression fractures
5. Weight gain
6. Heart failure

D. Interventions

1. Monitor vital signs.
2. Monitor intake and output, weight, and for edema.
3. Monitor electrolyte and calcium levels.
4. Instruct the client to take medication with food or milk.
5. Instruct the client to consume a high-potassium diet.
6. Instruct the client to report signs of illness.
7. Instruct the client to notify the PHCP if low blood pressure, weakness, cramping, palpitations, or changes in mental status occur.
8. Instruct the client to wear a MedicAlert bracelet.

! Instruct the client taking a corticosteroid not to stop the medication abruptly, because this could result in adrenal insufficiency.

VII. Corticosteroids: Glucocorticoids (Box 48.5)

A. Description

1. Glucocorticoids affect glucose, protein, and bone metabolism; alter the normal immune response and suppress inflammation; and produce antiallergic and antistress effects.
2. Glucocorticoids may be used as a replacement in adrenocortical insufficiency.
3. Glucocorticoids are used for their antiinflammatory and immunosuppressant effects both short-term and long-term in the treatment of several nonendocrine disorders.

B. Side and adverse effects

1. Adrenal insufficiency
2. Hyperglycemia
3. Hypokalemia
4. Hypocalcemia, osteoporosis
5. Sodium and fluid retention
6. Weight gain and edema
7. Mood swings
8. Fat redistribution resulting in moon face, buffalo hump, truncal obesity
9. Increased susceptibility to infection and masking of the signs and symptoms of infection
10. Cataracts
11. Hirsutism, acne, fragile skin, bruising
12. Growth retardation in children
13. GI irritation, peptic ulcer, pancreatitis
14. Seizures
15. Psychosis (usually occurs with hydrocortisone and dexamethasone in clients receiving very high doses long-term and is most likely due to their effects on blood glucose)

C. Contraindications and cautions

1. Contraindicated in clients with hypersensitivity, psychosis, and fungal infections
2. Should be used with caution in clients with **diabetes mellitus**
3. Should be used with extreme caution in clients with infections because they mask the signs and symptoms of an infection
4. They can increase the potency of medications taken concurrently, such as aspirin and nonsteroidal antiinflammatory drugs, thus increasing the risk of GI bleeding and ulceration.
5. Use of potassium-losing diuretics increases potassium loss, resulting in hypokalemia.
6. Dexamethasone decreases the effects of orally administered anticoagulants and antidiabetic agents.
7. Barbiturates, phenytoin, and rifampin decrease the effect of prednisone.

D. Interventions

1. Monitor vital signs.
2. Monitor serum electrolyte and blood glucose levels.
3. Monitor for hypokalemia and hyperglycemia.
4. Monitor intake and output, weight, and for edema.
5. Monitor for hypertension.
6. Assess medical history for glaucoma, cataracts, peptic ulcer, mental health disorders, or diabetes mellitus.
7. Monitor the older client for signs and symptoms of increased osteoporosis.

BOX 48.5 Corticosteroids: Glucocorticoids

- Betamethasone
- Cortisone acetate
- Dexamethasone
- Hydrocortisone
- Methylprednisolone
- Prednisolone
- Prednisone
- Triamcinolone

Telegram & Insta: NCLEX_RN_Edu

8. Assess for changes in muscle strength.
9. Prepare a schedule as needed for the client, with information on short-term tapered doses.
10. Instruct the client that it is best to take medication in the early morning with food or milk.
11. Advise the client to eat foods high in potassium.
12. Instruct the client to avoid individuals with infections.
13. Advise the client to inform all PHCPs of the medication regimen.
14. Instruct the client to report signs and symptoms of **Cushing's syndrome**, including a moon face, puffy eyelids, edema in the feet, increased bruising, dizziness, bleeding, and menstrual irregularities. These signs and symptoms often result from the large doses of long-term glucocorticoids that may be used to treat nonendocrine conditions.
15. Note that the client may need additional doses during periods of stress, such as surgery.
16. Instruct the client not to stop the medication abruptly, because abrupt withdrawal can result in severe adrenal insufficiency.
17. Advise the client to consult with the PHCP before receiving vaccinations; live virus vaccines should not be administered to the client taking glucocorticoids.
18. Advise the client to wear a MedicAlert bracelet.

VIII. Androgens (Box 48.6)

A. Description
1. Used to replace deficient hormones or to treat hormone-sensitive disorders
2. Can cause bleeding if the client is taking oral anticoagulants (increase the effect of anticoagulants)
3. Can cause decreased serum glucose concentration, thereby reducing insulin requirements in the client with diabetes mellitus
4. Hepatotoxic medications are avoided with the use of androgens because of the risk of additive damage to the liver.
5. Androgens usually are avoided in those with known prostate or breast carcinoma, because androgens often stimulate growth of these tumors.

B. Side and adverse effects
1. Masculine secondary sexual characteristics (body hair growth, lowered voice, muscle growth)
2. Bladder irritation and urinary tract infections
3. Breast tenderness
4. Gynecomastia
5. Priapism
6. Menstrual irregularities
7. Virilism
8. Sodium and water retention with edema
9. Nausea, vomiting, or diarrhea

BOX 48.6 Androgens

- Methyltestosterone

Testosterone Preparations
- Testosterone, pellets
- Testosterone, transdermal
- Testosterone cypionate
- Testosterone enanthate
- Testosterone propionate
- Testosterone undecanoate
- Testosterone, buccal patch
- Testosterone, topical gel
- Testosterone, nasal gel

10. Acne
11. Changes in libido
12. Hepatotoxicity, jaundice
13. Hypercalcemia

C. Interventions
1. Monitor vital signs.
2. Monitor for edema, weight gain, and skin changes.
3. Assess mental status and neurological function.
4. Assess for signs of liver dysfunction, including right upper quadrant abdominal pain, malaise, fever, jaundice, and pruritus.
5. Assess for the development of secondary sexual characteristics.
6. Instruct the client to take medication with meals or a snack.
7. Instruct the client to notify the PHCP if priapism develops.
8. Instruct the client to notify the PHCP if fluid retention occurs.
9. Instruct the client to use a nonhormonal contraceptive while on therapy.
10. Monitor for menstrual irregularities and decreased breast size.

IX. Estrogens and Progestins

A. Description
1. Estrogens are steroids that stimulate reproductive tissue.
2. Progestins are steroids that specifically stimulate the uterine lining.
3. Estrogen and progestin preparations may be used to stimulate the endogenous hormones to restore hormonal balance or to treat hormone-sensitive tumors (suppress tumor growth) or for contraception (Boxes 48.7 and 48.8).

B. Contraindications and cautions
1. Estrogens
   a. Estrogens are contraindicated in clients with breast cancer, endometrial hyperplasia, endometrial cancer, history of thromboembolism, known or suspected pregnancy, or lactation.

Telegram & Insta: NCLEX_RN_Edu

BOX 48.7 Estrogens

- Esterified estrogens
- Estradiol
- Estrogens, conjugated
- Ethinyl estradiol

BOX 48.8 Progestins

- Estradiol/drospirenone
- Estradiol/norgestimate
- Estradiol/levonorgestrel
- Estradiol/norethindrone
- Estradiol/etonogestrel
- Medroxyprogesterone acetate
- Medroxyprogesterone and conjugated estrogens
- Megestrol acetate
- Norethindrone acetate
- Levonorgestrel
- Progesterone

b. Use estrogens with caution in clients with hypertension, gallbladder disease, or liver or kidney dysfunction.

c. Estrogens increase the risk of toxicity when used with hepatotoxic medications.

d. Barbiturates, phenytoin, and rifampin decrease the effectiveness of estrogen.

2. Progestins are contraindicated in clients with thromboembolic disorders and should be avoided in clients with breast tumors or hepatic disease.

C. Side and adverse effects

1. Breast tenderness, menstrual changes

2. Nausea, vomiting, and diarrhea

3. Malaise, depression, excessive irritability

4. Weight gain

5. Edema and fluid retention

6. Atherosclerosis

7. Hypertension, stroke, myocardial infarction

8. Thromboembolism (estrogen)

9. Migraine headaches and vomiting (estrogen)

D. Interventions

1. Monitor vital signs.

2. Monitor for hypertension.

3. Assess for edema and weight gain.

4. Advise the client not to smoke.

5. Advise the client to undergo routine breast and pelvic examinations.

X. Medications for Diabetes Mellitus

A. Insulin and oral antidiabetic medications (see Clinical Judgment: Generate Solutions Box)

1. Description

a. Insulin increases glucose transport into cells and promotes conversion of glucose to glycogen, decreasing serum glucose levels.

b. Oral antidiabetic agents act in a number of ways: stimulate the pancreas to produce more insulin, increase the sensitivity of peripheral receptors to insulin, decrease hepatic glucose output, delay intestinal absorption of glucose, enhance the activity of incretins, and promote glucose loss through the kidney.

2. Contraindications and concerns

a. Oral antidiabetic agents, except the sodium-glucose cotransporter 2 (SGLT-2) inhibitors, are contraindicated in type 1 diabetes mellitus.

b. β-Adrenergic blocking agents may mask signs and symptoms of hypoglycemia associated with hypoglycemia-producing medications.

c. Anticoagulants, chloramphenicol, salicylates, propranolol, monoamine oxidase inhibitors, pentamidine, and sulfonamides may cause hypoglycemia.

d. Corticosteroids, sympathomimetics, thiazide diuretics, phenytoin, thyroid preparations, oral contraceptives, and estrogen compounds may cause hyperglycemia.

e. Side and adverse effects of the sulfonylureas include GI symptoms and dermatological reactions; hypoglycemia can occur when an excessive dose is administered or when meals are omitted or delayed, food intake is decreased, or activity is increased.

⚠ Sulfonylureas can cause a disulfiram type of reaction when alcohol is ingested.

B. Medications for type 2 diabetes mellitus (Table 48.1)

1. Interventions

a. Assess the client's knowledge of diabetes mellitus and the use of oral antidiabetic agents.

b. Obtain a medication history regarding the medications that the client is taking currently.

c. Assess vital signs and blood glucose levels.

d. Instruct the client to recognize the signs and symptoms of hypoglycemia and hyperglycemia.

e. Instruct the client to avoid over-the-counter medications unless prescribed by the PHCP.

f. Instruct the client not to ingest alcohol with sulfonylureas.

g. Inform the client that insulin may be needed during times of increased stress, surgery, or infection.

h. Instruct the client on the necessity for compliance with prescribed medication.

Telegram & Insta: NCLEX_RN_Edu

TABLE 48.1 Medications for Type 2 Diabetes

Class and Specific Agents	Actions	Major Adverse Effects
Oral Medications		
Biguanides		
Metformin	Decreases glucose production by the liver; increases tissue response to insulin	Gastrointestinal (GI) symptoms: decreased appetite, nausea, diarrhea
Second-Generation Sulfonylureas		
Glimepiride Glipizide Glyburide[a]	Promote insulin secretion by the pancreas; may also increase tissue response to insulin	Hypoglycemia Weight gain
Meglitinides (Glinides)		
Nateglinide Repaglinide	Promote insulin secretion by the pancreas	Hypoglycemia Weight gain
Thiazolidinediones (Glitazones)		
Pioglitazone Rosiglitazone	Decrease insulin resistance, thereby increasing glucose uptake by muscle and adipose tissue and decreasing glucose production by the liver	Hypoglycemia, but only in the presence of excessive insulin Heart failure Bladder cancer Fractures Ovulation and thus possible unintended pregnancy
α-Glucosidase Inhibitors		
Acarbose Miglitol	Delay carbohydrate digestion and absorption, thereby decreasing the postprandial rise in blood glucose	GI symptoms: flatulence, cramps, abdominal distention, borborygmus
DPP-4 Inhibitors (Gliptins)		
Alogliptin Linagliptin Saxagliptin Sitagliptin	Enhance the activity of incretins (by inhibiting their breakdown by DPP-4), thereby stimulating a decrease in blood glucose levels, increasing insulin release, reducing glucagon release, and decreasing hepatic glucose production	Pancreatitis Hypersensitivity reactions
Sodium-Glucose Cotransporter 2 (SGLT-2) Inhibitors		
Canagliflozin Dapagliflozin Empagliflozin Ertugliflozin (a combination with metformin is available)	Increase glucose excretion via the urine by inhibiting SGLT-2 in the kidney tubules, decreasing glucose levels and inducing weight loss via caloric loss through the urine	Genital mycotic infections Orthostatic hypotension
Dopamine Agonist		
Bromocriptine	Activates dopamine receptors in the central nervous system; how it improves glycemic control is unknown	Orthostatic hypotension Exacerbation of psychosis
Noninsulin Injectable Medications		
Glucagon-like Peptide-1 Agonists		
Incretin Mimetics		
Dulaglutide Exenatide Exenatide extended-release Semaglutide	Lower blood glucose by slowing gastric emptying, stimulating glucose-dependent insulin release, suppressing postprandial glucagon release, and reducing appetite	Hypoglycemia GI symptoms: nausea, vomiting, diarrhea Pancreatitis Renal insufficiency Thyroid C cell tumor (semaglutide)
Amylin Mimetics		
Pramlintide	Delays gastric emptying and suppresses glucagon secretion, decreasing the postprandial rise in glucose	Hypoglycemia Nausea Injection-site reactions

[a]Commonly known as *glibenclamide* outside the United States.

Adapted from Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care*. (10th ed.). St. Louis: Elsevier. p. 693.

i. Instruct the client about how to take each specific medication, such as with the first bite of the meal for meglitinides and α-glucosidase inhibitors.

j. Advise the client to wear a MedicAlert bracelet.

Metformin needs to be withheld temporarily before and for 48 hours after having any radiological study that involves the administration of intravenous contrast dye because of the risk of contrast-induced nephropathy and lactic acidosis. The PHCP needs to be consulted for specific prescriptions.

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: GENERATE SOLUTIONS

The nurse is reviewing the medical record of a hospitalized client scheduled later that day for a computerized tomography (CT) scan with an intravenous contrast dye. On review of the record the nurse notes that the client has diabetes mellitus and is taking metformin. The nurse prepares to take the following actions:

- Contact the radiology department to inform them that the client is taking metformin and for rescheduling the scan.
- Check with the primary health care provider about the time for withholding the metformin after the scan is completed.
- Encourage fluid intake after the scan is completed.
- Check the serum creatinine level before resuming the metformin.

C. Insulin

1. Insulin acts primarily in the liver, muscle, and adipose tissue by attaching to receptors on cellular membranes and facilitating the passage of glucose, potassium, and magnesium.

2. Insulin is prescribed for clients with type 1 diabetes mellitus and for clients with type 2 diabetes mellitus whose blood glucose levels are not adequately controlled with oral antidiabetic agents.

3. The onset, peak, and duration of action depend on the insulin type (Tables 48.2 and 48.3).

4. Storing of insulin (Box 48.9)

5. Insulin injection sites

a. The main areas for injections are the abdomen, arms (posterior surface), thighs (anterior surface), and hips (Fig. 48.1).

b. Insulin injected into the abdomen may absorb more evenly and rapidly than at other sites.

c. Systematic rotation within one anatomical area is recommended to prevent lipodystrophy and to promote more even absorption; clients should be instructed not to use the same site more than once in a 2- to 3-week period.

d. Injections should be 1 to 1.5 inches (2.5 to 3.8 cm) apart within the anatomical area.

e. Heat, massage, and exercise of the injected area can increase absorption rates and may result in hypoglycemia.

f. Injection into scar tissue may delay absorption of insulin.

6. Administering insulin (also see Chapter 47)

Insulin glargine cannot be mixed with any other types of insulin.

a. To prevent dosage errors, be certain that there is a match between the insulin concentration noted on the vial and the calibration of units on the insulin syringe; the usual concentration of insulin is U-100 (100 units/mL).

b. The Humulin R brand of regular insulin is the only insulin that is formulated in a U-500 strength. U-500 strength insulin is reserved for clients with severe insulin resistance who require large doses of insulin. A special syringe calibrated for use with U-500 insulin is required.

c. Prefilled syringes (pens) are commonly used; a new needle needs to be attached before each injection.

d. Most insulin syringes have a 27- to 29-gauge needle that is about 0.5-inch long (1.3 cm).

TABLE 48.2 Types of Insulin: Time Course of Activity After Subcutaneous Injection

	Time Course		
Generic Name	**Onset (min)**	**Peak (hr)**	**Duration (hr)**
Short Duration: Rapid Onset			
Insulin lispro	15-30	0.5-2.5	3-6
Insulin aspart	10-20	1-3	3-5
Insulin glulisine	10-15	1-1.5	3-5
Short Duration: Slower Onset			
Regular insulin	30-60	1-5	6-10
Intermediate Duration			
NPH insulin	60-120	6-14	16-24
Long Duration			
Insulin glargine	70	None	18-24
Insulin detemir	60-120	12-24	Varies
Insulin degludec	60-120	None	>40 Hours

Adapted from Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care*. (10th ed.). St. Louis: Elsevier. p. 684.

Telegram & Insta: NCLEX_RN_Edu

TABLE 48.3 Premixed Insulin Combinations[a]

Description	Time Course		
	Onset (min)	Peak (hr)	Duration (hr)
70% NPH insulin/30% regular insulin (Humulin)	30-60	1.5-16	10-16
70% NPH insulin/30% regular insulin (Novolin)	30-60	2-12	10-16
50% NPH insulin/50% regular insulin	30-60	2-12	10-16
70% insulin aspart protamine/30% insulin aspart	10-20	1-4	15-18
75% insulin lispro protamine/25% insulin lispro	15-30	1-6.5	10-16
50% insulin lispro protamine/50% insulin lispro	15-30	0.8-4.8	10-16

[a]Use only after the dosages and ratios of the components have been established as correct for the client.
Adapted from Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care*. (10th ed.). St. Louis: Elsevier. p. 688.

BOX 48.9 Storing Insulin

- Avoid exposing insulin to extremes in temperature.
- Insulin should not be frozen or kept in direct sunlight or in a hot car.
- Before injection, insulin should be at room temperature.
- If a vial of insulin will be used up in 1 month, it may be kept at room temperature; otherwise, the vial should be refrigerated.

e. NPH insulin is an insulin suspension; the appearance is cloudy. All other insulin types are solutions; the appearance of all other insulin products is clear.

f. Before use, NPH insulins must be rotated, or rolled, between the palms to ensure that the insulin suspension is mixed well; otherwise, an inaccurate dose will be drawn; vigorously shaking the bottle will cause bubbles to form. It is not necessary to rotate or roll clear insulins before using.

g. Inject air into the insulin bottle (a vacuum makes it difficult to draw up the insulin).

h. When mixing insulins, draw up the shortest-acting insulin first.

i. Short-duration (i.e., regular, lispro, aspart, and glulisine) insulin may be mixed with NPH.

j. Administer a mixed dose of insulin within 5 to 15 minutes of preparation; after this time, the short-acting insulin binds with the NPH insulin and its action is reduced.

k. Aspiration after insertion of the needle generally is not recommended with self-injection of insulin.

l. Administer insulin at a 45- to 90-degree angle in clients with normal subcutaneous mass and at a 45- to 60-degree angle in thin persons or those with a decreased amount of subcutaneous mass.

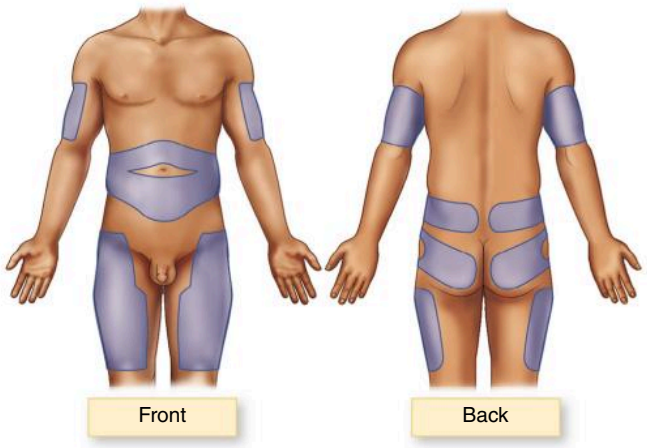

FIG. 48.1 Common insulin injection sites.

Some rapid- and short-acting insulins can be administered intravenously.

D. Glucagon-like peptide (GLP-1) receptor agonists

1. Noninsulin injectable agents that are analogs of human GLP-1 and cause the same effects as the GLP-1 incretin hormone in the body, which are to stimulate the glucose level–dependent release of insulin, to suppress the postprandial release of glucagon, to slow gastric emptying, and to suppress appetite

2. Used for clients with type 2 diabetes mellitus (not recommended for clients with type 1 diabetes, nor should clients be taken off insulin and given a GLP-1 receptor agonist)

3. GLP-1 receptor agonists restore the first-phase insulin response (first 10 minutes after food ingestion), lower the production of glucagon after meals, slow gastric emptying (which limits the rise in blood glucose level after a meal), reduce fasting and postprandial blood glucose levels, and reduce caloric intake, resulting in weight loss.

4. Packaged in premeasured doses (pens) that require refrigeration (cannot be frozen)

Telegram & Insta: NCLEX_RN_Edu

5. Administered as a subcutaneous injection in the thigh, abdomen, or upper arm; usually prescribed twice daily or once weekly, depending on the medication
6. Because delayed gastric emptying slows the absorption of other medications, other prescribed oral medications should be given an hour before injection of these medications.

E. Amylin mimetic: pramlintide

1. Synthetic form of amylin, a naturally occurring hormone secreted by the pancreas
2. Used for clients with types 1 and 2 diabetes mellitus who use insulin; administered subcutaneously before meals to lower blood glucose level after meals, leading to less fluctuation during the day and better long-term glucose control
3. Associated with an increased risk of insulin-induced severe hypoglycemia, particularly in clients with type 1 diabetes mellitus
4. GI effects, including nausea, can occur.
5. Unopened vials are refrigerated; opened vials can be refrigerated or kept at room temperature for up to 28 days.
6. Reduces postprandial hyperglycemia by delaying gastric emptying and suppressing postprandial glucagon release
7. Because pramlintide delays gastric emptying, other prescribed oral medications should be given 1 hour before or 2 hours after an injection of pramlintide.

F. Glucagon

1. Hormone secreted by the alpha cells of the islets of Langerhans in the pancreas
2. Increases blood glucose level by stimulating glycogenolysis in the liver and also can be administered for a beta blocker overdose.
3. Can be administered subcutaneously, intramuscularly, or intravenously
4. Used to treat insulin-induced hypoglycemia when the client is semiconscious or unconscious and is unable to ingest liquids
5. The blood glucose level begins to increase within 5 to 20 minutes after administration.
6. Instruct the family in the procedure for administration.
7. See Chapter 47 for additional information regarding insulin and interventions for hypoglycemia.

PRACTICE QUESTIONS

1. The nurse is teaching a client with diabetes mellitus how to mix regular insulin and NPH insulin in the same syringe. Which action, if performed by the client, indicates the **need for further teaching?**

1. Withdraws the NPH insulin first
2. Withdraws the regular insulin first
3. Injects air into NPH insulin vial first
4. Injects an amount of air equal to the desired dose of insulin into each vial

2. The home care nurse visits a client recently diagnosed with diabetes mellitus who is taking Humulin NPH insulin daily. The client asks the nurse how to store the unopened vials of insulin. The nurse would tell the client to take which action?

1. Freeze the insulin.
2. Refrigerate the insulin.
3. Store the insulin in a dark, dry place.
4. Keep the insulin at room temperature.

3. Glimepiride is prescribed for a client with diabetes mellitus. The nurse instructs the client that which food items are **most** acceptable to consume while taking this medication? **Select all that apply.**

❑ 1. Alcohol
❑ 2. Red meats
❑ 3. Whole-grain cereals
❑ 4. Low-calorie desserts
❑ 5. Carbonated beverages

4. The nurse is providing discharge teaching for a client newly diagnosed with type 2 diabetes mellitus who has been prescribed metformin. Which client statement indicates the **need for further teaching**?

1. "It is okay if I skip meals once in a while."
2. "I need to let my doctor know if I get unusually tired."
3. "I need to constantly watch for signs of low blood sugar."
4. "I will be sure to not drink alcohol excessively while on this medication."

5. The primary health care provider (PHCP) prescribes semaglutide for a client with type 1 diabetes mellitus who takes insulin. The nurse would plan to take which **most appropriate** intervention?

1. Withhold the medication and call the PHCP, questioning the prescription for the client.
2. Teach the client about the signs and symptoms of hypoglycemia and hyperglycemia.
3. Monitor the client for gastrointestinal side effects after administering the medication.
4. Withdraw the insulin from the prefilled pen into an insulin syringe to prepare for administration.

6. A client with diabetes mellitus is taking Humulin NPH insulin and regular insulin every morning. The nurse would provide which instructions to the client? **Select all that apply.**

❑ 1. Hypoglycemia may be experienced before dinnertime.
❑ 2. The insulin dose needs to be decreased if illness occurs.

Telegram & Insta: NCLEX_RN_Edu

❑ 3. The insulin should be administered at room temperature.
❑ 4. The insulin vial needs to be shaken vigorously to break up the precipitates.
❑ 5. The NPH insulin would be drawn into the syringe first, then the regular insulin.

7. The home health care nurse is visiting a client who was recently diagnosed with type 2 diabetes mellitus. The client is prescribed repaglinide and metformin. The nurse would provide which instructions to the client? **Select all that apply.**
❑ 1. Diarrhea may occur secondary to the metformin.
❑ 2. The repaglinide is not taken if a meal is skipped.
❑ 3. The repaglinide is taken 30 minutes before eating.
❑ 4. A simple sugar food item is carried and used to treat mild hypoglycemia episodes.
❑ 5. Muscle pain is an expected effect of metformin and may be treated with acetaminophen.
❑ 6. Metformin increases hepatic glucose production to prevent hypoglycemia associated with repaglinide.

8. The nurse is teaching the client about prescribed prednisone. Which statement, if made by the client, indicates that **further teaching is necessary**?
1. "I can take aspirin or my antihistamine if I need it."
2. "I need to take the medication every day at the same time."
3. "I need to avoid coffee, tea, cola, and chocolate in my diet."
4. "If I gain 5 pounds or more a week, I will call my doctor."

9. A client with hyperthyroidism has been given methimazole. Which nursing considerations are associated with this medication? **Select all that apply.**
❑ 1. Administer methimazole with food.
❑ 2. Place the client on a low-calorie, low-protein diet.
❑ 3. Assess the client for unexplained bruising or bleeding.
❑ 4. Instruct the client to report side and adverse effects such as sore throat, fever, or headaches.
❑ 5. Use special radioactive precautions when handling the client's urine for the first 24 hours following initial administration.

10. The nurse is monitoring a client receiving levothyroxine sodium for hypothyroidism. Which findings indicate the presence of a side effect associated with this medication? **Select all that apply.**
❑ 1. Insomnia
❑ 2. Weight loss
❑ 3. Bradycardia
❑ 4. Constipation
❑ 5. Mild heat intolerance

11. The nurse provides instructions to a client who is taking levothyroxine. The nurse would tell the client to take the medication in which way?
1. With food
2. At lunchtime
3. On an empty stomach
4. At bedtime with a snack

12. The nurse would tell the client who is taking levothyroxine to notify the primary health care provider (PHCP) if which problem occurs?
1. Fatigue
2. Tremors
3. Cold intolerance
4. Excessively dry skin

13. The nurse is providing instructions to the client newly diagnosed with diabetes mellitus who has been prescribed pramlintide. Which instruction would the nurse include in the discharge teaching?
1. "Inject the pramlintide at the same time you take your other medications."
2. "Take your prescribed pills 1 hour before or 2 hours after the injection."
3. "Be sure to take the pramlintide with food so that you don't upset your stomach."
4. "Make sure you take your pramlintide immediately after you eat so that you don't experience a low blood sugar."

14. The nurse teaches the client who is newly diagnosed with diabetes insipidus about the prescribed intranasal desmopressin. Which statements by the client indicate understanding? **Select all that apply.**
❑ 1. "This medication will turn my urine orange."
❑ 2. "I need to decrease my oral fluids when I start this medication."
❑ 3. "The amount of urine I make should increase if this medicine is working."
❑ 4. "I need to follow a low-fat diet to avoid pancreatitis when taking this medicine."
❑ 5. "I need to report headache and drowsiness to my doctor since these symptoms could be related to my desmopressin."

Telegram & Insta: NCLEX_RN_Edu

15. A daily dose of prednisone is prescribed for a client. The nurse provides instructions to the client regarding administration of the medication and would instruct the client that which time is **best** to take this medication?
1. At noon
2. At bedtime
3. Early morning
4. Any time, at the same time, each day

16. The client with hyperparathyroidism is taking alendronate. Which statements by the client indicate understanding of the proper way to take this medication? **Select all that apply.**
- ❑ 1. "I need to take this medication with food."
- ❑ 2. "I need to take this medication at bedtime."
- ❑ 3. "I need to sit up for at least 30 minutes after taking this medication."
- ❑ 4. "I need to take this medication first thing in the morning on an empty stomach."
- ❑ 5. "I can pick a time to take this medication that best fits my lifestyle as long as I take it at the same time each day."

17. A client with diabetes mellitus visits a health care clinic. The client's diabetes mellitus previously had been well controlled with glyburide daily, but recently the fasting blood glucose level has been 180 to 200 mg/dL (10 to 11.1 mmol/L). Which medication, if added to the client's regimen, may have contributed to the hyperglycemia?
1. Atenolol
2. Prednisone
3. Phenelzine
4. Allopurinol

ANSWERS

1. *Answer:* 1

Rationale: When preparing a mixture of short-acting insulin, such as regular insulin, with another insulin preparation, the short-acting insulin is drawn into the syringe first. This sequence will avoid contaminating the vial of short-acting insulin with insulin of another type. Options 2, 3, and 4 identify correct actions for preparing NPH and short-acting insulin.

Test-Taking Strategy: Note the **strategic words,** *need for further teaching*. These words indicate a **negative event query** and ask you to select an option that is an incorrect action. Remember *RN*—draw up the *R*egular *(short-acting)* insulin before the *N*PH insulin.

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 507.

2. *Answer:* 2

Rationale: Insulin in unopened vials needs to be stored under refrigeration until needed. Vials are not to be frozen. When stored unopened under refrigeration, insulin can be used up to the expiration date on the vial. Options 1, 3, and 4 are incorrect.

Test-Taking Strategy: Note the **subject,** how to store unopened vials of insulin. Options 3 and 4 are **comparable or alike** regarding where to store the insulin and would be eliminated. Remembering that insulin is not to be frozen will assist in eliminating option 1.

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 507.

3. *Answer:* 2, 3, 5

Rationale: When alcohol is combined with glimepiride, a disulfiram-like reaction may occur. This syndrome includes flushing, palpitations, and nausea. Alcohol can also potentiate the hypoglycemic effects of the medication. Clients need to be instructed to avoid alcohol consumption while taking this medication. Low-calorie desserts should also be avoided. Even though the calorie content may be low, carbohydrate content is most likely high and can affect the blood glucose. The items in options 2, 3, and 5 are acceptable to consume.

Test-Taking Strategy: Note the **strategic word,** *most*. Remembering that alcohol can affect the action of many medications will assist in eliminating option 1. Next, recalling that carbohydrates need to be controlled in a diabetic diet will assist in eliminating option 4.

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 693, 695; Kizior, R., & Hodgson, B. (2021). *Saunders nursing drug handbook 2021*. St. Louis: Elsevier. p. 557.

4. *Answer:* 3

Rationale: Metformin is classified as a biguanide and is the most commonly used medication for type 2 diabetes mellitus initially. It is also often used as a preventive medication for those at high risk for developing diabetes mellitus. When used alone, metformin lowers the blood glucose after meal intake, as well as fasting blood glucose levels. Metformin does not stimulate insulin release and therefore poses little risk for hypoglycemia. For this reason, metformin is well suited for clients who skip meals. Unusual somnolence as well as hyperventilation, myalgia, and malaise are early signs of lactic acidosis, a toxic effect associated with metformin. If any of these signs or symptoms occur, the client needs to inform the primary health care provider immediately. While it is best to avoid consumption of alcohol, it is not always realistic or feasible for clients to quit drinking altogether; for this reason, clients need to be informed that excessive alcohol intake can cause an adverse reaction with metformin.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Note the **strategic words**, *need for further teaching*. These words indicate a **negative event query** and the need to select the incorrect client statement as the answer. Recalling the adverse effects and drug interactions associated with this medication will assist you in eliminating options 2 and 4. Next, recalling the mechanism of action of this medication will help you determine that this medication is suited for clients who skip meals, thereby leading you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1118, 1120.

5. *Answer:* 1

Rationale: Semaglutide is a glucagon-like peptide-1 agonist used for type 2 diabetes mellitus only. It is not recommended for clients with type 1 diabetes. Hence the nurse would withhold the medication and question the PHCP regarding this prescription. Although options 2 and 3 are correct statements about the medication, in this situation the medication would not be administered. The medication is packaged in prefilled pens ready for injection without the need for drawing it up into another syringe.

Test-Taking Strategy: Note the **strategic words,** *most appropriate*. Focus on the name of the medication, recalling that it is used for the treatment of type 2 diabetes mellitus. Eliminate option 4 because the medication is packaged in prefilled pens ready for injection. From the remaining options, focus on the **data in the question.** Although options 2 and 3 are appropriate when administering this medication, this client would not receive this medication.

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. p. 693; Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1275-1276.

6. *Answer:* 1, 3

Rationale: Humulin NPH is an intermediate-acting insulin. The onset of action is 60 to 120 minutes, it peaks in 6 to 14 hours, and its duration of action is 16 to 24 hours. Regular insulin is a short-acting insulin. Depending on the type, the onset of action is 30 to 60 minutes, it peaks in 1 to 5 hours, and its duration is 6 to 10 hours. Hypoglycemic reactions most likely occur during peak time. Insulin should be at room temperature when administered. Clients may need their insulin dosages increased during times of illness. Insulin vials would never be shaken vigorously. Regular insulin is always drawn up before NPH.

Test-Taking Strategy: Focus on the **subject,** client instructions regarding insulin. Eliminate option 4 because of the word *vigorously.* Use knowledge regarding the characteristics of insulin; procedures for administration; and the onset, peak, and duration of action for insulin and insulin administration to select from the remaining options. Remember that NPH insulin peaks in 6 to 14 hours and that regular insulin peaks in 1 to 5 hours.

Reference: Kizior, R., & Hodgson, B. (2021). *Saunders nursing drug handbook 2021*. St. Louis: Elsevier. p. 618.

7. *Answer:* 1, 2, 3, 4

Rationale: Repaglinide, a rapid-acting oral hypoglycemic agent that stimulates pancreatic insulin secretion, is to be taken before meals (approximately 30 minutes before meals) and would be withheld if the client does not eat. Hypoglycemia is a side effect of repaglinide, and the client needs to be prepared by carrying a simple sugar at all times. Metformin is an oral hypoglycemic given in combination with repaglinide and works by decreasing hepatic glucose production. A common side effect of metformin is diarrhea. Muscle pain may occur as an adverse effect from metformin, but it might signify a more serious condition that warrants primary health care provider notification, not the use of acetaminophen.

Test-Taking Strategy: Focus on the **subject,** oral medications to treat diabetes mellitus. Thinking about the pathophysiology of diabetes mellitus and recalling the actions and effects of these medications are needed to answer correctly.

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 696, 708.

8. *Answer:* 1

Rationale: Aspirin and other over-the-counter medications would not be taken unless the client consults with the PHCP. The client needs to take the medication at the same time every day and would be instructed not to stop the medication. A slight weight gain as a result of an improved appetite is expected; however, after the dosage is stabilized, a weight gain of 5 pounds (2.25 kg) or more weekly needs to be reported to the PHCP. Caffeine-containing foods and fluids need to be avoided because they may contribute to steroid-ulcer development.

Test-Taking Strategy: Note the **strategic words,** *further teaching is necessary.* These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Remember that a client taking prednisone would not take other medications, especially over-the-counter medications, without first consulting with the PHCP.

References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 879-880; Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 1034.

9. *Answer:* 1, 3, 4

Rationale: Common side effects of methimazole include nausea, vomiting, and diarrhea. To address these side effects, this medication needs to be taken with food. Because of the increase in metabolism that occurs in hyperthyroidism, the client needs to consume a high-calorie diet. Antithyroid medications can cause agranulocytosis with leukopenia and thrombocytopenia. Sore throat, fever, headache, or bleeding may indicate agranulocytosis, and the primary health care provider needs to be notified immediately. Methimazole is not radioactive and would not be stopped abruptly, due to the risk of thyroid storm.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Focus on the **subject,** nursing considerations for administering methimazole. Focus on the client's diagnosis. Think about the pathophysiology associated with the diagnosis and the medication and the actions and effects of antithyroid medications to assist in answering correctly.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 821-822.

10. *Answer:* 1, 2, 5
Rationale: Insomnia, weight loss, and mild heat intolerance are side effects of levothyroxine sodium. Bradycardia and constipation are not side effects associated with this medication, and rather are associated with hypothyroidism, which is the disorder that this medication is prescribed to treat.
Test-Taking Strategy: Focus on the **subject,** side effects of levothyroxine. Thinking about the pathophysiology of hypothyroidism and the action of the medication will assist you in determining that insomnia, weight loss, and mild heat intolerance are side effects of thyroid hormones.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1157.

11. *Answer:* 3
Rationale: Oral doses of levothyroxine need to be taken on an empty stomach to enhance absorption. Dosing would be done in the morning before breakfast.
Test-Taking Strategy: Note that options 1, 2, and 4 are **comparable or alike** in that these options address administering the medication with food.
Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. pp. 698-699.

12. *Answer:* 2
Rationale: Excessive doses of levothyroxine can produce signs and symptoms of hyperthyroidism. These include tachycardia, chest pain, tremors, nervousness, insomnia, hyperthermia, extreme heat intolerance, and sweating. The client would be instructed to notify the PHCP if these occur. Options 1, 3, and 4 are signs of hypothyroidism.
Test-Taking Strategy: Focus on the **subject,** the need to notify the PHCP. Recall the symptoms associated with hypothyroidism, the purpose of administering levothyroxine, and the effects of the medication. Options 1, 3, and 4 are symptoms related to hypothyroidism.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1157.

13. *Answer:* 2
Rationale: Pramlintide is used for clients with types 1 and 2 diabetes mellitus who use insulin. It is administered subcutaneously before meals to lower blood glucose level after meals, leading to less fluctuation during the day and better long-term glucose control. Because pramlintide delays gastric emptying, any prescribed oral medications would be taken 1 hour before or 2 hours after an injection of pramlintide; therefore, instructing clients to take their pills 1 hour before or 2 hours after the injection is correct. Pramlintide would not be taken at the same time as other medications. Pramlintide is given immediately before the meal in order to control postprandial rise in blood glucose, not necessarily to prevent stomach upset. It is incorrect to instruct the client to take the medication after eating, as it will not achieve its full therapeutic effect.
Test-Taking Strategy: Focus on the **subject,** client instructions regarding pramlintide as it pertains to administration. Use knowledge regarding the action of the medication and treatment measures for diabetes mellitus to answer the question. Remember that this medication is used in conjunction with insulin to prevent postprandial rise in blood glucose and that hypoglycemia is a potential adverse effect. Also remember that this medication causes delayed gastric emptying and should not be taken with other medications.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 702-703.

14. *Answer:* 2, 5
Rationale: In diabetes insipidus, there is a deficiency in antidiuretic hormone (ADH), resulting in large urinary losses. Desmopressin is an antidiuretic hormone that enhances reabsorption of water in the kidney. Clients with diabetes insipidus drink high volumes of fluid (polydipsia) as a compensatory mechanism to counteract urinary losses and maintain fluid balance. Once desmopressin is started, oral fluids need to be decreased to prevent water intoxication. Therefore, clients with diabetes insipidus need to decrease their oral fluid intake when they start desmopressin. Headache and drowsiness are signs of water intoxication in the client taking desmopressin and need to be reported to the primary health care provider. Desmopressin does not turn urine orange. The amount of urine would decrease, not increase, when desmopressin is started. Desmopressin does not cause pancreatitis.
Test-Taking Strategy: Focus on the **subject,** understanding of desmopressin. Recall that in diabetes insipidus there is a deficiency of ADH and that desmopressin is an antidiuretic hormone. Recalling the pathophysiology of this disorder will assist you in answering correctly.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 373-375.

15. *Answer:* 3
Rationale: Corticosteroids (glucocorticoids) need to be administered before 9 a.m. Administration at this time helps minimize adrenal insufficiency and mimics the burst of glucocorticoids released naturally by the adrenal glands each morning. Options 1, 2, and 4 are incorrect.
Test-Taking Strategy: Note the **strategic word,** *best.* Note the suffix *-sone* and recall that medication names that end with these letters are corticosteroids. Remember that a daily dose of a corticosteroid needs to be administered in the morning.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 520.

Telegram & Insta: NCLEX_RN_Edu

16. ***Answer:*** **3, 4**

Rationale: Alendronate is a bisphosphonate used in hyperparathyroidism to inhibit bone loss and normalize serum calcium levels. Esophagitis is an adverse effect of primary concern in clients taking alendronate. For this reason the client is instructed to take alendronate first thing in the morning with a full glass of water on an empty stomach, not to eat or drink anything else for at least 30 minutes after taking the medication, and to remain sitting upright for at least 30 minutes after taking it.

Test-Taking Strategy: Focus on the **subject,** the correct method to take alendronate. Recall that the primary concern with alendronate is esophagitis. Eliminate options 1 and 2, since taking with food and taking at bedtime will each place the client at increased risk of reflux. Eliminate option 5 because alendronate needs to be taken first thing in the morning on an empty stomach.

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. pp. 910-912.

17. ***Answer:*** **2**

Rationale: Prednisone may decrease the effect of oral hypoglycemics, insulin, diuretics, and potassium supplements. Option 1, a beta blocker, and option 3, a monoamine oxidase inhibitor, have their own intrinsic hypoglycemic activity. Option 4 decreases urinary excretion of sulfonylurea agents, causing increased levels of the oral agents, which can lead to hypoglycemia.

Test-Taking Strategy: Focus on the **subject,** an increase in the blood glucose level. Recalling that prednisone is a corticosteroid and that corticosteroids decrease the effects of hypoglycemics will direct you to the correct option.

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 517, 521.

UNIT X

Gastrointestinal Problems of the Adult Client

Pyramid to Success

Pyramid Points focus on diagnostic tests and nursing care related to gastrointestinal problems, gastric or intestinal tubes, gastric surgery, cirrhosis, hepatitis, pancreatitis, and colostomy care. Preprocedure and postprocedure care of the client undergoing a gastrointestinal diagnostic test is a focus. Remember that an informed consent is required for any invasive procedure. Important points include diet restrictions and safety implications before and after the diagnostic test. Pyramid Points also include instructions to the client and family regarding the prevention of gastrointestinal problems and the complications associated with the problem. Client and family teaching about diet and nutrition specific to the problem, tube and wound care, preventing the transmission of infection such as with hepatitis, and care of a colostomy or ileostomy is addressed. Psychological impact in clients with a gastrointestinal problem is noted, with a specific focus on the client with a diversion, such as an ileostomy or colostomy; the social isolation issues that can occur; and effective coping strategies.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Consulting with the interprofessional team regarding the client's care and nutritional status
Ensuring that confidentiality issues related to the gastrointestinal problem are maintained
Ensuring that informed consent for treatments and surgical procedures has been obtained
Handling infectious drainage and secretions safely
Maintaining standard precautions and other precautions as appropriate
Obtaining referrals for home care and community services
Preventing disease transmission
Prioritizing hypotheses based on client needs

Health Promotion and Maintenance

Generating solutions for effective colostomy or ileostomy care
Performing physical assessment techniques of the gastrointestinal system
Preventing disease related to the gastrointestinal system
Providing health screening and health promotion programs related to gastrointestinal problems
Recognizing cues that indicate a gastrointestinal problem
Teaching on prescribed dietary and other treatment measures
Teaching on preventing the transmission of disease

Psychosocial Integrity

Assessing coping mechanisms
Considering end-of-life and grief and loss issues
Identifying available support systems
Monitoring for concerns related to body image changes

Physiological Integrity

Administering medications as prescribed specific to the gastrointestinal problem
Analyzing cues related to infectious diseases of the gastrointestinal tract
Assisting with personal hygiene
Evaluating outcomes for treatment effectiveness
Monitoring elimination patterns

Telegram & Insta: NCLEX_RN_Edu

Monitoring for complications related to tests, procedures, and surgical interventions
Monitoring for fluid and electrolyte imbalances
Monitoring laboratory values related to gastrointestinal problems
Monitoring parenterally administered fluids, including total parenteral nutrition (TPN)
Providing adequate nutrition and oral hydration
Providing care for gastrointestinal tubes
Providing nonpharmacological and pharmacological comfort measures
Providing preprocedure and postprocedure care for diagnostic tests related to the gastrointestinal system
Taking action in emergency situations

CHAPTER 49

Gastrointestinal Problems

Contributor: Jessica Grimm, DNP, APRN, ACNP-BC, CNE

PRIORITY CONCEPTS **Elimination; Nutrition**

I. Anatomy and Physiology

A. Functions of the gastrointestinal (GI) system
1. Process food substances
2. Absorb the products of digestion into the blood
3. Excrete unabsorbed materials
4. Provide an environment for microorganisms to synthesize nutrients, such as vitamin K
5. For risk factors associated with the GI problems, see Box 49.1.

B. Mouth
1. Contains the lips, cheeks, palate, tongue, teeth, salivary glands, muscles, and maxillary bones
2. Saliva contains the enzyme amylase (ptyalin), which aids in digestion.

C. Esophagus
1. Collapsible muscular tube about 7 to 10 inches (18 to 25 cm) long
2. Carries food from the pharynx to the stomach

D. Stomach
1. Contains the cardia, fundus, body, and pylorus
2. Mucous glands are located in the mucosa and prevent autodigestion by providing an alkaline protective covering.
3. The lower esophageal (cardiac) sphincter prevents reflux of gastric contents into the esophagus.
4. The pyloric sphincter regulates the rate of stomach emptying into the small intestine.
5. Hydrochloric acid kills microorganisms, breaks food into small particles, and provides a chemical environment that facilitates gastric enzyme activation.
6. Pepsin is the chief coenzyme of gastric juice, which converts proteins into proteoses and peptones.
7. Intrinsic factor comes from parietal cells and is necessary for the absorption of vitamin B_{12}.
8. Gastrin controls gastric acidity.

E. Small intestine
1. The duodenum is the first 8 to 10 inches (20 to 25 cm) and is attached to the distal end of the pylorus; it contains the openings of the bile and pancreatic ducts.
2. The jejunum is about 8 feet (2.5 meters) long.
3. The ileum is about 12 feet (3.7 meters) long.
4. The small intestine terminates in the cecum.

F. Pancreatic intestinal juice enzymes
1. Amylase digests starch to maltose.
2. Maltase reduces maltose to monosaccharide glucose.
3. Lactase splits lactose into galactose and glucose.
4. Sucrase reduces sucrose to fructose and glucose.
5. Nucleases split nucleic acids to nucleotides.
6. Enterokinase activates trypsinogen to trypsin.

G. Large intestine
1. About 5 feet (1.5 meters) long
2. Absorbs water and eliminates wastes
3. Intestinal bacteria play a vital role in the synthesis of some B vitamins and vitamin K.
4. Colon: Includes the ascending, transverse, descending, and sigmoid colons and rectum
5. The ileocecal valve prevents contents of the large intestine from entering the ileum.
6. The internal and external anal sphincters control the anal canal.
7. The anal canal is the last 1 to 1.5 inches (3 to 4 cm) of the large intestine.

H. Peritoneum: Lines the abdominal cavity and forms the mesentery that supports the intestines and blood supply

Telegram & Insta: NCLEX_RN_Edu

BOX 49.1 Risk Factors Associated with the Gastrointestinal System

- Allergic reactions to food or medications
- Cardiac, respiratory, and endocrine disorders that may lead to slowed gastrointestinal (GI) movement or constipation
- Chronic alcohol use
- Chronic high stress levels
- Chronic laxative use
- Chronic use of aspirin or nonsteroidal antiinflammatory drugs (NSAIDs)
- Diabetes mellitus, which may predispose to oral candidal infections or other GI disorders
- Family history of GI disorders (colorectal cancer, inflammatory bowel disease)
- Long-term GI conditions, such as ulcerative colitis, that may predispose to colorectal cancer
- Neurological disorders that can impair movement, particularly with chewing and swallowing
- Previous abdominal surgery or trauma, which may lead to adhesions
- Tobacco use

BOX 49.2 Common Gastrointestinal System Diagnostic Studies[a]

- Abdominal ultrasound
- Capsule endoscopy
- Computerized tomography (CT) scan
- Endoscopic retrograde cholangiopancreatography (ERCP)
- Endoscopic ultrasound
- Fiberoptic colonoscopy
- Gastric analysis
- Gastrointestinal motility studies
- Hydrogen and urea breath test
- Laparoscopy: Liver and pancreas laboratory studies
- Liver biopsy
- Magnetic resonance cholangiopancreatography (MRCP)
- Magnetic resonance imaging
- Paracentesis
- Stool specimens
- Sigmoidoscopy
- Upper gastrointestinal endoscopy or esophagogastroduodenoscopy
- Upper gastrointestinal tract study (barium swallow)
- Videofluoroscopic swallowing study

[a] Informed consent is obtained for a diagnostic study that is invasive.
References: Ignatavicius, Workman, Rebar, Heimgartner (2021), p.1071; Lewis et al. (2020), p. 843-844.

I. Liver
  1. The largest gland in the body, weighing 3 to 4 pounds (1.4 to 1.8 kg)
  2. Contains Kupffer cells, which remove bacteria in the portal venous blood
  3. Removes excess glucose and amino acids from the portal blood
  4. Synthesizes glucose, amino acids, and fats
  5. Aids in the digestion of fats, carbohydrates, and proteins
  6. Stores and filters blood (200 to 400 mL of blood stored)
  7. Stores vitamins A, D, and B and iron
  8. The liver secretes bile to emulsify fats (500 to 1000 mL of bile/day).
  9. Hepatic ducts
    a. Deliver bile to the gallbladder via the cystic duct and to the duodenum via the common bile duct
    b. The common bile duct opens into the duodenum, with the pancreatic duct at the ampulla of Vater.
    c. The sphincter prevents the reflux of intestinal contents into the common bile duct and pancreatic duct.

J. Gallbladder
  1. Stores and concentrates bile and contracts to force bile into the duodenum during the digestion of fats
  2. The cystic duct joins the hepatic duct to form the common bile duct.
  3. The sphincter of Oddi is located at the entrance to the duodenum.
  4. The presence of fatty materials in the duodenum stimulates the liberation of cholecystokinin, which causes contraction of the gallbladder and relaxation of the sphincter of Oddi.

K. Pancreas
  1. Exocrine gland
    a. Secretes sodium bicarbonate to neutralize the acidity of the stomach contents that enter the duodenum
    b. Pancreatic juices contain enzymes for digesting carbohydrates, fats, and proteins.
  2. Endocrine gland
    a. Secretes glucagon to raise blood glucose levels and secretes somatostatin to exert a hypoglycemic effect
    b. The islets of Langerhans secrete insulin.
    c. Insulin is secreted into the bloodstream and is important for carbohydrate metabolism.

II. Diagnostic Procedures (Box 49.2)

A. Upper GI tract study (barium swallow)
  1. Description: Examination of the upper GI tract under fluoroscopy after the client drinks barium sulfate
  2. Preprocedure: Withhold foods and fluids for 4 to 8 hours prior to the test.
  3. Postprocedure
    a. A laxative may be prescribed.
    b. Instruct the client to increase oral fluid intake to help pass the barium.

Telegram & Insta: NCLEX_RN_Edu

c. Monitor stools for the passage of barium (stools will appear gray or chalky white for 24 to 72 hours postprocedure) because barium can cause a bowel obstruction.

B. Capsule endoscopy

1. Description: A procedure that uses a small wireless camera shaped like a medication capsule that the client swallows; the test will detect bleeding or changes in the lining of the small intestine.
2. The camera travels through the entire digestive tract and sends multiple pictures to a small box that the client wears like a belt; the small box saves the pictures, which are then transferred to a computer for viewing once the test is complete.
3. The client visits the gastroenterologist's office in the morning and swallows the capsule, and the recording belt is applied by the office staff. Then the client returns at the end of the day so that pictures can be transferred to the computer.
4. Preprocedure:
   a. A bowel preparation will be prescribed.
   b. Informed consent needs to be obtained.
   c. The client will need to maintain a clear liquid diet on the evening before the exam; additionally, NPO (nothing by mouth) status is maintained for the first 2 hours of testing (time for NPO status is prescribed by the gastroenterologist).
   d. Clients may need to reduce insulin amounts during the NPO period according to the gastroenterologist's recommendations.
5. Postprocedure:
   a. Observe vital signs.
   b. Inform the client that the sedation may cause amnesia for a few hours.

C. Gastric analysis

1. Description
   a. Gastric analysis can be used to assess clients with recurrent ulcers after surgical vagotomy.
   b. Gastric analysis requires the passage of a nasogastric (NG) tube into the stomach to aspirate gastric contents for the analysis of acidity (pH), appearance, and volume; the entire gastric contents are aspirated, and then specimens are collected every 15 minutes for 1 hour. Gastric analysis tests gastric output in basal and stimulated states.
   c. Medication, such as histamine or pentagastrin, may be administered subcutaneously to stimulate gastric secretions; some medications may produce a flushed feeling.
   d. Esophageal reflux of gastric acid may be diagnosed by ambulatory pH monitoring; a probe is placed just above the lower esophageal sphincter and connected to an external recording device. It provides a computer analysis and graphic display of results.
2. Preprocedure
   a. Fasting for at least 8 to 12 hours is required before the test.
   b. Use of tobacco and chewing gum is avoided for 24 hours before the test.
   c. Medications that stimulate gastric secretions are withheld for 24 to 48 hours.
   d. Informed consent needs to be obtained.
3. Postprocedure
   a. Client may resume normal activities.
   b. Refrigerate gastric samples if not tested within 4 hours.

D. Upper GI endoscopy

1. Description
   a. Also known as esophagogastroduodenoscopy
   b. Following sedation, an endoscope is passed down the esophagus to view the gastric wall, sphincters, and duodenum; tissue specimens can be obtained.
2. Preprocedure
   a. Informed consent needs to be obtained.
   b. The client must be NPO for 6 to 8 hours before the test.
   c. Clients are usually advised to avoid anticoagulants and nonsteroidal antiinflammatory drugs for several days before the test unless otherwise indicated by their primary health care provider.
   d. A local anesthetic (spray or gargle) is administered along with medication that provides moderate sedation just before the scope is inserted.
   e. Medication may be administered to reduce secretions, and medication may be administered to relax smooth muscle.
   f. The client is positioned on the left side to facilitate saliva drainage and to provide easy access of the endoscope.
   g. Airway patency is monitored during the test, and pulse oximetry is used to monitor oxygen saturation; emergency equipment should be readily available.
3. Postprocedure
   a. Monitor vital signs.
   b. Client must be NPO until the gag reflex returns (1 to 2 hours). NPO status may be maintained longer if the client required intervention during the procedure or if ongoing bleeding is unresolved.
   c. Monitor for signs of perforation (pain, bleeding, unusual difficulty in swallowing, elevated temperature).
   d. Maintain bed rest and keep side rails raised (per agency policy) for the sedated client until alert.
   e. Lozenges, saline gargles, or oral analgesics can relieve a minor sore throat (but are not given to the client until the gag reflex returns).

Telegram & Insta: NCLEX_RN_Edu

E. Fiberoptic colonoscopy

1. Description

a. Colonoscopy is a fiberoptic endoscopy study in which the lining of the large intestine is visually examined; biopsies and polypectomies can be performed.

b. Cardiac and respiratory function is monitored continuously during the test.

c. Colonoscopy is performed with the client lying on the left side with the knees drawn up to the chest; position may be changed during the test to facilitate passing of the scope.

2. Preprocedure

a. Adequate cleansing of the colon is necessary, as prescribed by the PHCP.

b. A clear liquid diet is started on the day before the test. Red, orange, and purple (grape) liquids are to be avoided.

c. Consult with the gastroenterologist regarding medications that must be withheld before the test.

d. Client is NPO for 4 to 6 hours prior to the test.

e. Informed consent needs to be obtained.

f. Moderate sedation is administered intravenously.

g. Medication may be administered to relax smooth muscle.

3. Postprocedure

a. Monitor vital signs.

b. Provide bed rest and keep side rails up (per agency policy) until alert.

c. Do not allow anything by mouth until the client is alert.

d. Maintain left lateral position to promote passing of flatus.

e. Monitor for signs of bowel perforation and peritonitis (Box 49.3).

f. Remind the client that passing flatus, abdominal fullness, and mild cramping are expected for several hours.

g. Instruct the client to report any bleeding to the PHCP.

h. Teach the client to avoid activities requiring concentration and decision-making.

The client receiving oral liquid bowel cleansing preparations or enemas is at risk for fluid and electrolyte imbalances.

F. Laparoscopy is performed with a fiberoptic laparoscope that allows direct visualization of organs and structures within the abdomen; biopsies may be obtained.

BOX 49.3 Signs of Bowel Perforation and Peritonitis

- Guarding of the abdomen
- Abdominal distention
- Nausea and vomiting
- Diminished bowel sounds
- Inability to pass flatus
- Rebound tenderness or "Blumberg's sign"
- Increased temperature
- Pallor
- Progressive abdominal distention and abdominal pain
- Restlessness or altered mental status
- Tachycardia and tachypnea
- Dizziness and light-headedness
- Decreased blood pressure and tachycardia

G. Endoscopic retrograde cholangiopancreatography (ERCP)

1. Description

a. ERCP is often used when an intervention will probably be required. If an intervention is unlikely, a noninvasive diagnostic test is preferred.

b. Examination of the hepatobiliary system is performed via a flexible endoscope inserted into the esophagus to the descending duodenum; multiple positions are required during the procedure to pass the endoscope.

c. If medication is administered before the procedure, the client is monitored closely for signs of respiratory and central nervous system depression, hypotension, oversedation, and vomiting.

2. Preprocedure

a. Client is NPO for 6 to 8 hours.

b. Informed consent needs to be obtained.

c. Inquire about previous exposure to contrast media and any sensitivities or allergies.

d. Avoid anticoagulants and nonsteroidal antiinflammatory drugs unless otherwise indicated by the primary health care provider.

e. Clients are asked about implantable medical devices and are asked to have them deactivated if present.

f. Moderate sedation is administered.

3. Postprocedure

a. Monitor vital signs.

b. Monitor for the return of the gag reflex, and wait to provide food and fluids until gag reflex has returned.

Telegram & Insta: NCLEX_RN_Edu

c. Monitor for signs of perforation or peritonitis (see Box 49.3).
d. If the intervention was completed, monitor lab values postprocedure, including liver enzymes and pancreatic enzymes.

H. Magnetic resonance cholangiopancreatography (MRCP)
1. Description: Uses magnetic resonance to visualize the biliary and pancreatic ducts in a noninvasive way. This test is often used as a noninvasive alternative to ERCP.
2. Preprocedure and postprocedure: See Chapter 59 discussing MRI.

I. Endoscopic ultrasonography
1. Description: Provides images of the GI wall and digestive organs
2. Preprocedure and postprocedure: Care is similar to that implemented for endoscopy.

⚠ Following endoscopic procedures, monitor for the return of the gag reflex before giving the client any oral substance. If the gag reflex has not returned, the client could aspirate.

J. Computed tomography (CT) scan
1. Description
   a. Noninvasive cross-sectional view that can detect tissue densities in the abdomen, including in the liver, spleen, pancreas, and biliary tree.
   b. Can be performed with or without contrast medium.
2. Preprocedure
   a. Client is NPO for at least 4 hours.
   b. If contrast medium will be used, assess for previous sensitivities and allergies.
   c. Encourage the client to verbalize concerns because some clients have claustrophobia.
3. Postprocedure
   a. Encourage client to drink fluids to avoid dye-induced renal failure and to promote dye excretion.
   b. Inform client that diarrhea may occur after ingestion of oral contrast.

K. Paracentesis
1. Description
   a. A procedure in which a needle or catheter is inserted into the peritoneal cavity to obtain or remove fluid for diagnostic or therapeutic purposes.
   b. The fluid may be used to help determine the cause of ascites and to evaluate for infection or the presence of cancer.
2. Preprocedure (see Clinical Judgment: Take Action Box)

CLINICAL JUDGMENT: TAKE ACTION BOX

A 59-year-old client with ascites is scheduled to have a paracentesis. The nurse would take the following actions to prepare the client for the procedure:

- Ensure that the client understands the procedure and that informed consent has been obtained.
- Obtain vital signs.
- Obtain weight.
- Assist the client to void and empty the bladder.
- Measure abdominal girth.
- Position the client upright.

3. Postprocedure
   a. Assist the primary health care provider (PHCP) in providing comfort and support during the procedure.
   b. Apply a dressing to the site of puncture; monitor the site for bleeding.
   c. Monitor for hematuria caused by bladder trauma.
   d. Monitor vital signs, especially blood pressure and pulse, and monitor for mental status changes because these parameters provide information postparacentesis on rapid vasodilation; maintain the client on bed rest.
   e. Measure abdominal girth and weight (the client should experience a weight loss).
   f. Monitor for hypovolemia and electrolyte loss.
   g. Measure the amount of fluid removed, and document the amount and a description of the fluid.
   h. Label and send the fluid for laboratory analysis; testing should be performed immediately to avoid false results because of chemical or cellular deterioration.
   i. Document the event, the client's response, and the appearance and amount of fluid removed.
   j. Instruct the client to notify the PHCP if the urine becomes bloody, pink, or red.

⚠ The rapid removal of fluid from the abdominal cavity during paracentesis leads to decreased abdominal pressure, which can cause vasodilation and resultant shock; therefore, heart rate and blood pressure must be monitored closely.

L. Liver biopsy
1. Description: A needle is inserted through the abdominal wall to the liver to obtain a tissue sample for biopsy and microscopic examination.

Telegram & Insta: NCLEX_RN_Edu

2. Preprocedure (see Clinical Judgment: Take Action Box)
   a. Informed consent needs to be obtained.
   b. Withhold food and fluid for 8 to 12 hours before the procedure.
   c. Perform a baseline assessment, including vital signs.
   d. Assess results of coagulation tests (prothrombin time, partial thromboplastin time, platelet count), and obtain blood typing and crossmatch.
   e. Teach the client about postprocedure care, and explain the need to hold breath after expiration when the needle is inserted.
   f. Administer a sedative as prescribed.
   g. Note that the client is placed in the supine or left lateral position during the procedure to expose the right side of the upper abdomen.
3. Postprocedure
   a. Assess vital signs.
   b. Assess biopsy site for bleeding.
   c. Monitor for peritonitis (see Box 49.3).
   d. Maintain bed rest for 12 to 14 hours as prescribed.
   e. Place the client on the right side with a pillow under the costal margin for 2 hours to decrease the risk of bleeding, and instruct the client to avoid coughing and straining.
   f. Instruct the client to avoid heavy lifting and strenuous exercise for 1 week and to avoid coughing or straining, which may cause increased intra-abdominal pressure.
   g. Notify the primary health care provider if dyspnea, cyanosis, or restlessness occurs as these are signs of pneumothorax.

CLINICAL JUDGMENT: TAKE ACTION

The nurse is preparing a client for a liver biopsy. During review of the client's laboratory results, the nurse notes that the client's prothrombin time is 35 seconds and platelet count is 100,000 mm^3 (100×10^9 /L). Based on these findings, the nurse would take the following action:

- The client's prothrombin time is prolonged and the platelet count is low, placing the client at risk for bleeding. Therefore, the nurse must immediately notify the primary health care provider of these abnormal laboratory values and place the client on bleeding precautions.

M. Stool specimens
1. Testing of stool specimens includes inspecting the specimen for consistency and color and testing for occult blood.
2. Tests for fecal urobilinogen, fat, nitrogen, parasites, pathogens, food substances, and other substances may be performed; these tests require that the specimen be sent to the laboratory.
3. Random specimens are sent promptly to the laboratory.
4. Quantitative 24- to 72-hour collections must be kept refrigerated until they are taken to the laboratory.
5. Some specimens require that a certain diet be followed or that certain medications be withheld; check agency guidelines regarding specific procedures.

N. Urea breath test
1. The urea breath test detects the presence of *Helicobacter pylori*, the bacteria that cause peptic ulcer disease.
2. The client consumes a capsule of carbon-labeled urea and provides a breath sample 10 to 20 minutes later.
3. Certain medications may need to be avoided before testing. These may include antibiotics or bismuth subsalicylate for 1 month before the test; sucralfate and omeprazole for 1 week before the test; and cimetidine, famotidine, and nizatidine for 24 hours before breath testing.
4. *H. pylori* can also be detected by assessing serum antibody levels.

O. Esophageal pH testing for gastroesophageal reflux disease
1. Used to diagnose or evaluate the treatment for heartburn or reflux disease
2. A probe is inserted into the nostril and is situated in the esophagus.
3. pH is tested over a period of 24 to 48 hours.

P. Liver and pancreas laboratory studies
1. Liver enzyme levels (alkaline phosphatase [ALP], aspartate aminotransferase [AST], and alanine aminotransferase [ALT]) are elevated with liver damage or biliary obstruction. Normal reference intervals: ALP, 38-126 U/L (0.65-2.14 µkat/L); AST, 0 to 35 U/L (0 to 35 U/L); ALT, 4 to 36 U/L (4 to 36 U/L).
2. Prothrombin time (PT), partial thromboplastin time (PTT), and international normalized ratio (INR) are elevated/prolonged with liver damage. PT normal reference interval: 11 to 12.5 seconds. PTT normal reference interval: 30 to 40 seconds. INR normal reference interval: 0.8 to 1.2.
3. The serum ammonia level assesses the ability of the liver to deaminate protein byproducts. Normal reference interval: 10 to 80 mcg/dL (6 to 47 mcmol/L).
4. An increase in cholesterol level indicates *pancreatitis* or biliary obstruction. Normal reference interval: less than 200 mg/dL (less than 5.0 mmol/L).

Telegram & Insta: NCLEX_RN_Edu

5. An increase in bilirubin level indicates liver damage or biliary obstruction. Normal reference intervals: total, 0.3 to 1.0 mg/dL (5.1 to 17 mcmol/L); indirect, 0.2 to 0.8 mg/dL (3.4 to 12 mcmol/L); direct, 0.1 to 0.3 mg/dL (1.7 to 5.1 mcmol/L).
6. Increased values for amylase and lipase levels indicate pancreatitis. Normal reference intervals: amylase, 60 to 120 Somogyi units/dL (100 to 300 U/L); lipase, 0 to 160 U/L (0 to 160 U/L).

III. Assessment: See Chapter 12 for abdominal assessment techniques.

IV. Gastrointestinal Tubes: See Chapter 70 for information regarding these tubes.

V. Gastroesophageal Reflux Disease

A. Description
1. The backflow of gastric and duodenal contents into the esophagus
2. The reflux is caused by an incompetent lower esophageal sphincter (LES), pyloric stenosis, or motility disorder.
3. Overweight or obesity are risk factors because the increased weight increases intra-abdominal pressure contributing to reflux.

B. Assessment
1. Heartburn, epigastric pain, chest pain
2. Voice hoarseness
3. Chronic dry cough (especially at night)
4. Dyspepsia
5. Nausea, regurgitation
6. Pain and difficulty with swallowing (odynophagia)
7. Globus (feeling of something in the back of the throat)
8. Hypersalivation

C. Interventions
1. Instruct the client to avoid factors that decrease LES pressure or cause esophageal irritation, such as peppermint, chocolate, coffee and caffeine, fried or fatty foods, carbonated beverages, alcoholic beverages, nitrates, citrus fruits, tomatoes and tomato products, and cigarette smoking.
2. Instruct the client to eat a low-fat, high-fiber diet and to avoid eating and drinking 2 hours before bedtime and wearing tight clothes; also, elevate the head of the bed on 6- to 8-inch (15 to 20 cm) blocks or pillows.
3. Small, frequent meals will help to prevent gastric distention; instruct the client not to lie down for 2 to 3 hours after eating and not to bend over after eating.
4. Avoid the use of anticholinergics, which delay stomach emptying; also, nonsteroidal antiinflammatory medications (NSAIDs) and other medications that contain acetylsalicylic acid need to be avoided, as well as calcium channel blockers.
5. Instruct the client regarding prescribed medications, such as antacids, H_2-receptor antagonists, or proton pump inhibitors.
6. Instruct the client regarding the administration of prokinetic medications, if prescribed, which accelerate gastric emptying.
7. Surgery may be required in extreme cases when medical management is unsuccessful; this involves a fundoplication (wrapping a portion of the gastric fundus around the sphincter area of the esophagus); surgery may be performed by laparoscopy.

VI. Gastritis

A. Description
1. Inflammation of the stomach or gastric mucosa
2. Acute gastritis is caused by the ingestion of food contaminated with disease-causing microorganisms or food that is irritating or too highly seasoned, the overuse of aspirin or other NSAIDs, excessive alcohol intake, bile reflux, or radiation therapy.
3. Chronic gastritis is caused by benign or malignant ulcers or by the bacteria *H. pylori*, and also may be caused by autoimmune diseases, dietary factors, medications, alcohol, smoking, or reflux.

B. Assessment (Box 49.4)

C. Interventions
1. Acute gastritis: Food and fluids may be withheld until symptoms subside; afterward, and as prescribed, ice chips can be given, followed by clear liquids, and then solid food.
2. Monitor for signs of hemorrhagic gastritis such as hematemesis, tachycardia, and hypotension, and notify the PHCP if these signs occur.
3. Instruct the client to avoid irritating foods, fluids, and other substances, such as spicy and highly seasoned foods, caffeine, alcohol, and nicotine.
4. Instruct the client in the use of prescribed medications, such as antibiotics to treat *H. pylori*, and antacids.
5. Provide the client with information about the importance of vitamin B_{12} injections if a deficiency is present.

VII. Peptic Ulcer Disease

A. Description
1. A peptic ulcer is an ulceration in the mucosal wall of the stomach, pylorus, duodenum, or esophagus in portions accessible to gastric secretions; erosion may extend through the muscle.
2. The ulcer may be referred to as *gastric*, *duodenal*, or *esophageal*, depending on its location.

Telegram & Insta: NCLEX_RN_Edu

BOX 49.4 Assessment Findings in Acute and Chronic Gastritis

Acute

- Abdominal discomfort
- Anorexia, nausea, and vomiting
- Headache
- Hiccupping
- Reflux or dyspepsia

Chronic

- Anorexia, nausea, and vomiting
- Belching
- Heartburn after eating
- Sour taste in the mouth
- Vitamin B_{12} deficiency

BOX 49.5 Assessment: Gastric and Duodenal Ulcers

Gastric

- Gnawing, sharp pain in or to the left of the midepigastric region occurs 1 to 2 hours after a meal (food ingestion accentuates the pain).
- Hematemesis is more common than melena.

Duodenal

- Burning pain occurs in the midepigastric area 2 to 5 hours after a meal and midmorning, midafternoon, and during the night (often awakens the client).
- Melena is more common than hematemesis.
- Pain is often relieved by the ingestion of food.

3. The most common peptic ulcers are gastric ulcers and duodenal ulcers.

B. Gastric ulcers

1. Description
   - **a.** A gastric ulcer involves ulceration of the mucosal lining that extends to the submucosal layer of the stomach.
   - **b.** Predisposing factors include stress, smoking, the use of corticosteroids, NSAIDs, alcohol, history of gastritis, family history of gastric ulcers, or infection with *H. pylori*.
   - **c.** Complications include hemorrhage, perforation, and pyloric obstruction.
2. Assessment (Box 49.5)
3. Interventions
   - **a.** Monitor vital signs and for signs of bleeding.
   - **b.** Administer small, frequent bland feedings during the active phase.
   - **c.** Administer H_2-receptor antagonists or proton pump inhibitors as prescribed to decrease the secretion of gastric acid.
   - **d.** Administer antacids as prescribed to neutralize gastric secretions.
   - **e.** Administer anticholinergics as prescribed to reduce gastric motility.
   - **f.** Administer mucosal barrier protectants as prescribed 1 hour before each meal.
   - **g.** Administer prostaglandins as prescribed for their protective and antisecretory actions.
   - **h.** Administer treatment for *Helicobacter pylori* where indicated and as prescribed by the PHCP.
4. Client education
   - **a.** Avoid consuming alcohol and substances that contain caffeine or chocolate.
   - **b.** Caffeinated and decaffeinated coffee should be avoided because it contains peptides that stimulate gastric release.
   - **c.** Avoid smoking.
   - **d.** Avoid aspirin or NSAIDs.
   - **e.** Obtain adequate rest and reduce stress, and follow healthy nutritional habits while avoiding substances that increase gastric acid secretions.
   - **f.** Instruct the client to take all prescribed medications, including antisecretory medications and antibiotics as prescribed, to prevent relapse.
5. Interventions during active bleeding
   - **a.** Monitor vital signs closely.
   - **b.** Assess for signs of hemorrhage, dehydration, hypovolemic shock, sepsis, and respiratory insufficiency.
   - **c.** Maintain NPO status and administer intravenous (IV) fluid replacement as prescribed; monitor intake and output.
   - **d.** Monitor hemoglobin and hematocrit.
   - **e.** Obtain type and screen when hemoglobin and hematocrit are stable; if unstable may need type and cross to prepare for blood transfusion.
   - **f.** Administer blood transfusions as prescribed.
   - **g.** Prepare to assist with administering medications as prescribed to induce vasoconstriction and reduce bleeding.

Upper GI bleeding can be life-threatening. The priority of care is to stabilize the client. Provide oxygen and other ventilatory support as needed. Two large-bore intravenous lines for replacing fluids and blood are usually needed. Vital signs, blood counts, and coagulation studies need to be monitored.

6. Surgical interventions
   - **a.** Total **gastrectomy**: Removal of the stomach with attachment of the esophagus to the jejunum or duodenum; also called *esophagojejunostomy* or *esophagoduodenostomy*
   - **b.** **Vagotomy**: Surgical division of the vagus nerve to eliminate the vagal impulses that stimulate hydrochloric acid secretion in the stomach

Telegram & Insta: NCLEX_RN_Edu

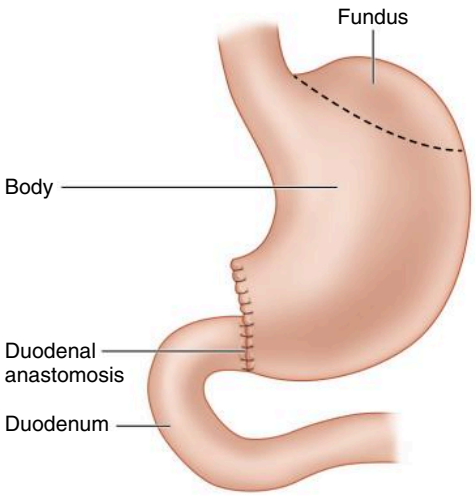

FIG. 49.1 The Billroth I procedure (gastroduodenostomy). The distal portion of the stomach is removed, and the remainder is anastomosed to the duodenum.

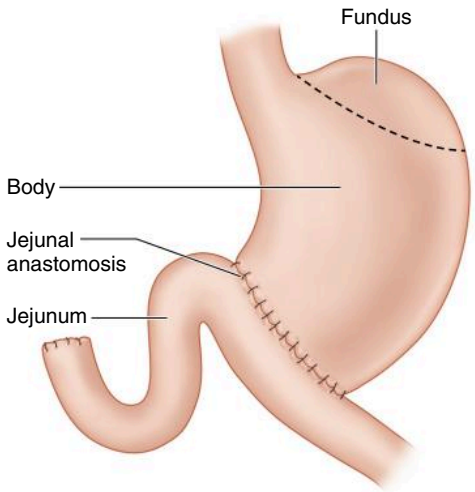

FIG. 49.2 The Billroth II procedure (gastrojejunostomy). The lower portion of the stomach is removed, and the remainder is anastomosed to the jejunum.

c. **Gastric resection**: Removal of the lower half of the stomach and usually includes a vagotomy; also called *antrectomy*

d. Gastroduodenostomy: Partial gastrectomy, with the remaining segment anastomosed to the duodenum; also called **Billroth I** (Fig. 49.1)

e. Gastrojejunostomy: Partial gastrectomy, with the remaining segment anastomosed to the jejunum; also called **Billroth II** (Fig. 49.2)

f. **Pyloroplasty:** Enlargement of the pylorus to prevent or decrease pyloric obstruction, thereby enhancing gastric emptying

7. Postoperative interventions

a. Monitor vital signs.

b. Place in a Fowler's position for comfort and to promote drainage.

c. Administer fluids and electrolyte replacements intravenously as prescribed; monitor intake and output.

d. Assess bowel sounds.

e. Monitor NG suction as prescribed.

f. Maintain NPO status as prescribed for 1 to 3 days until **peristalsis** returns.

g. Progress the diet from NPO to sips of clear water to six small bland meals a day, as prescribed when bowel sounds return.

h. Monitor for postoperative complications of hemorrhage, **dumping syndrome,** diarrhea, hypoglycemia, bile reflux gastritis, and vitamin B_{12} deficiency.

⚠ Following gastric surgery, do not irrigate or remove the NG tube unless specifically prescribed because of the risk for disruption of the gastric sutures. Monitor closely to ensure proper functioning of the NG tube to prevent strain on the anastomosis site. Contact the surgeon if the tube is not functioning properly.

C. Duodenal ulcers

1. Description

a. A duodenal ulcer is a break in the mucosa of the duodenum.

b. Risk factors and causes include infection with *H. pylori*; alcohol intake; smoking; stress; caffeine; and the use of aspirin, corticosteroids, and NSAIDs.

c. Complications include bleeding, perforation, gastric outlet obstruction, and intractable disease.

2. Assessment (see Box 49.5)

3. Interventions and client education

a. Monitor orthostatic vital signs.

b. Instruct the client about a bland diet, with small, frequent meals.

c. Provide for adequate rest.

d. Encourage the cessation of smoking.

e. Instruct the client to avoid intake of alcohol, caffeine, and caffeinated and decaffeinated coffee, and the use of aspirin, corticosteroids, and NSAIDs.

f. Administer medications to treat *H. pylori* and antacids to neutralize acid secretions as prescribed.

g. Administer H_2-receptor antagonists or proton pump inhibitors as prescribed to block the secretion of acid.

4. Surgical interventions: Surgery is performed only if the ulcer is unresponsive to medications or if hemorrhage, obstruction, or perforation occurs.

D. **Dumping syndrome**

1. Description: The rapid emptying of the gastric contents into the small intestine that occurs following gastric resection

2. Assessment

a. Symptoms occurring 30 minutes after eating

b. Nausea and vomiting

Telegram & Insta: NCLEX_RN_Edu

BOX 49.6 Client Education: Preventing Dumping Syndrome

- Eliminate caffeine containing products.
- Eat a high-protein and complex carbohydrate diet, include foods such as oatmeal and other whole-grain foods high in fiber; increase fiber intake as tolerated.
- Limit high-sugar foods, such as candy, table sugar, syrup, sodas and juices.
- Eat small meals, five or six small meals a day rather than three larger ones.
- Avoid consuming fluids with meals; drink most daily fluids between meals.
- Eliminate dairy products if they are causing a problem; lactose may worsen symptoms.
- Lie down for 20 to 30 minutes after meals to prevent rapid gastric emptying.
- Take vitamin B_{12} injections as prescribed.
- Take antispasmodic medications as prescribed to delay gastric emptying.
- Consult with the primary health care provider about drinking alcohol.

Reference: Ignatavicius, Workman, Rebar, Heimgartner (2021), pp.1107-1108.

c. Feelings of abdominal fullness and abdominal cramping
d. Diarrhea
e. Palpitations and tachycardia
f. Perspiration
g. Weakness and dizziness
h. Borborygmi (loud gurgling sounds resulting from bowel hypermotility)

3. Client education (Box 49.6)

VIII. Vitamin B_{12} Deficiency: See Chapter 45 for more information.

IX. Bariatric Surgery

A. Description
1. Surgical reduction of gastric capacity or absorptive ability that may be performed on a client with morbid obesity to produce long-term weight loss
2. Thorough psychological assessment and testing to detect depression, substance abuse, or other mental and behavioral health problems that could interfere with success after surgery is necessary.
3. Surgery may be performed by laparoscopy; the decision is based on the client's weight, body build, history of abdominal surgery, and current medical disorders.
4. Obese clients are at increased postoperative risk for pulmonary and thromboembolic complications and death.
5. Surgery can prevent the complications of obesity, such as diabetes mellitus, hypertension and other cardiovascular disorders, or sleep apnea.
6. The client needs to agree to modify their lifestyle, lose weight and keep the weight off, and obtain support from available community resources such as the American Obesity Association, American Society for Metabolic and Bariatric Surgery, or Overeaters Anonymous.

B. Types (Fig. 49.3)
C. Postoperative interventions
1. Care is similar to that for the client undergoing laparoscopic or abdominal surgery.
2. As prescribed, if the client can tolerate water, clear liquids are introduced slowly in 1-ounce (30 mL) cups for each serving once bowel sounds have returned and the client passes flatus.
3. As prescribed, clear fluids are followed by puréed foods, juices, thin soups, and milk 24 to 48 hours after clear fluids are tolerated (the diet is usually limited to liquids or puréed foods for 6 weeks); then the diet is progressed to nutrient-dense regular food.
4. Monitor for symptoms of anastomotic leaks as the most common serious complication and cause of death after gastric bypass surgery, and assess for abdominal pain, restlessness, unexplained tachycardia, and oliguria.

D. Client teaching points about diet (Box 49.7)

X. Gastric Cancer: See Chapter 45 for more information.

XI. Hiatal Hernia

A. Description
1. A **hiatal hernia** is also known as an *esophageal* or *diaphragmatic hernia.*
2. A portion of the stomach herniates through the diaphragm and into the thorax.
3. Herniation results from weakening of the muscles of the diaphragm and is aggravated by factors that increase abdominal pressure such as pregnancy, **ascites**, obesity, tumors, and heavy lifting.
4. Complications include ulceration, hemorrhage, regurgitation and aspiration of stomach contents, strangulation, and incarceration of the stomach in the chest with possible necrosis, peritonitis, and mediastinitis.

B. Assessment
1. Heartburn
2. Chest pain
3. Regurgitation or vomiting
4. Dysphagia
5. Feeling of fullness
6. Worsening of symptoms when lying down

C. Interventions
1. Medical and surgical management are similar to those for gastroesophageal reflux disease.
2. Provide small frequent meals and limit the amount of liquids taken with meals.

Telegram & Insta: NCLEX_RN_Edu

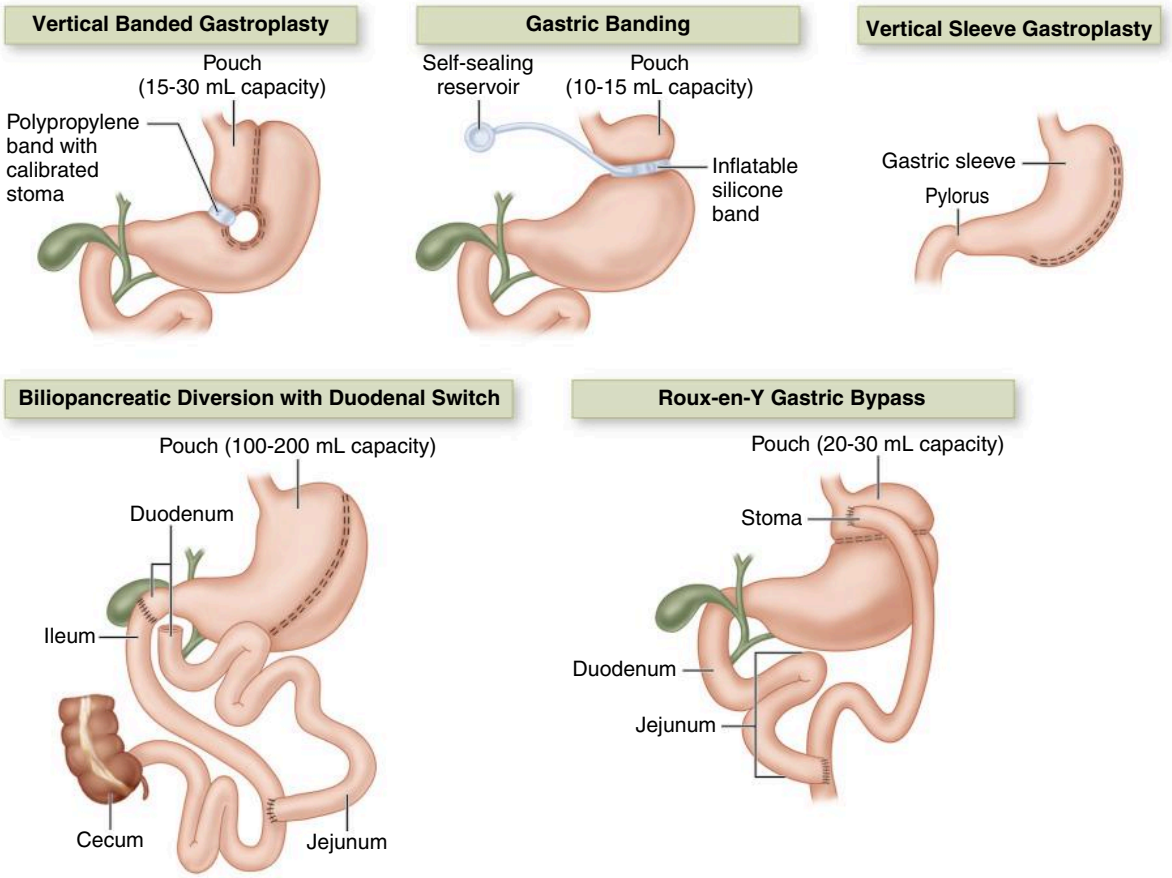

FIG. 49.3 Bariatric surgical procedures.

BOX 49.7 Dietary Measures for the Client Following Bariatric Surgery

- Avoid alcohol, high-protein foods, and foods high in sugar and fat.
- Eat slowly and chew food well.
- Progress food types and amounts as prescribed.
- Take nutritional supplements as prescribed, which may include calcium, iron, multivitamins, and vitamin B_{12}.
- Monitor and report signs and symptoms of complications, such as dehydration and gastric leak (persistent abdominal pain, nausea, vomiting).

Reference: Ignatavicius, Workman, Rebar, Heimgartner (2021), p.1214; Lewis et al. (2020), p.883.

3. Encourage the client to consume a well-balanced diet and to make lifestyle changes as indicated.
4. Advise the client not to recline for 1 hour after eating.
5. Avoid anticholinergics, which delay stomach emptying.

XII. Cholecystitis

A. Description

1. Inflammation of the gallbladder that may occur as an acute or chronic process
2. Acute inflammation is associated with gallstones (cholelithiasis).
3. Chronic **cholecystitis** results when inefficient bile emptying and gallbladder muscle wall disease cause a fibrotic and contracted gallbladder.
4. Acalculous cholecystitis occurs in the absence of gallstones and is caused by bacterial invasion via the lymphatic or vascular system.

B. Assessment

1. Nausea and vomiting
2. Indigestion
3. Belching
4. Flatulence
5. Epigastric pain that radiates to the right shoulder or scapula
6. Pain localized in the right upper quadrant and triggered by a high-fat or high-volume meal
7. Guarding, rigidity, and rebound tenderness
8. Mass palpated in the right upper quadrant
9. **Murphy's sign** (cannot take a deep breath when the examiner's fingers are passed below the hepatic margin because of pain)
10. Elevated temperature
11. Tachycardia
12. Signs of dehydration

Telegram & Insta: NCLEX_RN_Edu

C. Biliary obstruction (choledolithiasis)
1. Jaundice
2. Dark orange and foamy urine
3. Steatorrhea and clay-colored feces
4. Pruritus

D. Interventions
1. Maintain NPO status during nausea and vomiting episodes.
2. Maintain NG decompression as prescribed for severe vomiting.
3. Administer antiemetics as prescribed for nausea and vomiting.
4. Administer analgesics as prescribed to relieve pain and reduce spasm.
5. Administer antispasmodics (anticholinergics) as prescribed to relax smooth muscle.
6. Instruct the client with chronic cholecystitis to eat small, high-fiber, low-fat meals.
7. Instruct the client to avoid gas-forming foods.
8. Prepare the client for nonsurgical and surgical procedures as prescribed.

E. Surgical interventions
1. **Cholecystectomy** is the removal of the gallbladder.
2. **Choledocholithotomy** requires incision into the common bile duct to remove the stone.
3. Surgical procedures are commonly performed by laparoscopy.

F. Postoperative interventions
1. Monitor for respiratory complications caused by pain at the incisional site.
2. Encourage coughing and deep breathing and incentive spirometer use every 2 hours.
3. Encourage early ambulation.
4. Instruct the client about splinting the abdomen to prevent discomfort during coughing.
5. Administer antiemetics as prescribed for nausea and vomiting.
6. Administer analgesics as prescribed for pain relief.
7. Maintain NPO status and NG tube suction as prescribed.
8. Advance diet from clear liquids to solids when prescribed and as tolerated by the client.
9. Maintain and monitor drainage from the T-tube, if present; teach the client about its care if the client will be discharged with it in place (Box 49.8).

BOX 49.8 Care of a T-Tube

Purpose and Description

A T-tube is placed after surgical exploration of the common bile duct. The tube preserves the patency of the duct and ensures drainage of bile until edema resolves and bile is effectively draining into the duodenum. A gravity drainage bag is attached to the T-tube to collect the drainage.

Interventions

- Place the client in semi-Fowler's position to facilitate drainage.
- Monitor the output amount and the color, consistency, and odor of the drainage.
- Report sudden increases in bile output to the primary health care provider (PHCP).
- Monitor for inflammation and protect the skin from irritation.
- Keep the drainage system below the level of the gallbladder.
- Monitor for foul odor and purulent drainage and report its presence to the PHCP.
- Avoid irrigation, aspiration, or clamping of the T-tube without a PHCP's prescription.
- As prescribed, clamp the tube before a meal, and observe for abdominal discomfort and distention, nausea, chills, or fever; unclamp the tube if nausea or vomiting occurs.

XIII. Cirrhosis

A. Description
1. A chronic, progressive disease of the liver characterized by diffuse degeneration and destruction of hepatocytes
2. Repeated destruction of hepatic cells causes the formation of scar tissue.
3. Early signs are vague and nonspecific; assess for fatigue, significant weight changes, GI symptoms, anorexia and vomiting, abdominal pain, and liver tenderness.
4. Cirrhosis has many causes and is due to chronic damage and injury to liver cells; the most common are chronic hepatitis C, alcoholism, **nonalcoholic fatty liver disease (NAFLD)**, and **nonalcoholic steatohepatitis (NASH)**.

B. Complications
1. **Portal hypertension:** A persistent increase in pressure in the portal vein that develops as a result of obstruction to flow
2. **Ascites**
   - **a.** Accumulation of fluid in the peritoneal cavity that results from venous congestion of the hepatic capillaries
   - **b.** Capillary congestion leads to plasma leaking directly from the liver surface and portal vein.
3. Bleeding **esophageal varices**: Fragile, thin-walled, distended esophageal veins that become irritated and rupture
4. Coagulation defects
   - **a.** Decreased synthesis of bile fats in the liver prevents the absorption of fat-soluble vitamins.
   - **b.** Without vitamin K and clotting factors II, VII, IX, and X, the client is prone to bleeding and easy bruising.

Telegram & Insta: NCLEX_RN_Edu

Dermatological Findings
- Axillary and pubic hair changes
- Caput medusae (dilated abdominal veins)*
- Ecchymosis; petechiae*
- Increased skin pigmentation
- Jaundice
- Palmar erythema*
- Pruritus
- Spider angiomas (chest and thorax)*

Endocrine Findings
- Increased aldosterone
- Increased antidiuretic hormone
- Increased circulating estrogens
- Increased glucocorticoids
- Gynecomastia

Immune System Disturbances
- Increased susceptibility to infection
- Leukopenia

Renal Findings
- Hepatorenal syndrome
- Increased urine bilirubin

Fluid and Electrolyte Disturbances
- Ascites
- Decreased effective blood volume
- Hypocalcemia
- Dilutional hyponatremia or hypernatremia
- Hypokalemia
- Peripheral edema
- Water retention

Cardiovascular Findings
- Cardiac dysrhythmias
- Development of collateral circulation
- Fatigue
- Hyperkinetic circulation
- Peripheral edema
- Portal hypertension
- Spider angiomas

Hematological Findings
- Anemia
- Disseminated intravascular coagulation
- Impaired coagulation
- Splenomegaly
- Thrombocytopenia

Neurological Findings
- Asterixis
- Paresthesias of feet
- Peripheral nerve degeneration
- Portal-systemic encephalopathy
- Reversal of sleep-wake pattern
- Sensory disturbances

Pulmonary Findings
- Dyspnea
- Hydrothorax
- Hyperventilation
- Hypoxemia

Gastrointestinal (GI) Findings
- Abdominal pain
- Anorexia
- Ascites
- Clay-colored stools
- Diarrhea
- Esophageal varices
- Fetor hepaticus
- Gallstones
- Gastritis
- Gastrointestinal bleeding
- Hemorrhoidal varices
- Hepatomegaly
- Hiatal hernia
- Hypersplenism
- Malnutrition
- Nausea
- Small nodular liver
- Vomiting

FIG. 49.4 Clinical picture of a client with liver dysfunction. Manifestations vary according to the progression of the disease. Some dermatological manifestations are noted in color (and marked with asterisks).

5. Jaundice: Occurs because the liver is unable to metabolize bilirubin and because the edema, fibrosis, and scarring of the hepatic bile ducts interfere with normal bile and bilirubin secretion
6. Portal systemic encephalopathy: End-stage hepatic failure characterized by altered level of consciousness, neurological symptoms, impaired thinking, and neuromuscular disturbances; caused by failure of the diseased liver to detoxify neurotoxic agents such as ammonia
7. Hepatorenal syndrome
   a. Progressive renal failure associated with hepatic failure
   b. Characterized by a sudden decrease in urinary output, elevated blood urea nitrogen and creatinine levels, decreased urine sodium excretion, and increased urine osmolarity

C. Assessment (Fig. 49.4)

D. Interventions

1. Elevate the head of the bed to minimize shortness of breath.
2. If ascites and edema are absent and the client does not exhibit signs of impending coma, a high-protein diet supplemented with vitamins is prescribed.
3. Provide supplemental vitamins (B complex; vitamins A, C, and K; folic acid; and thiamine) as prescribed.
4. Restrict sodium intake and fluid intake as prescribed.
5. Initiate enteral feedings or parenteral nutrition as prescribed.
6. Administer diuretics as prescribed to treat ascites.
7. Monitor intake and output and electrolyte balance.
8. Weigh client and measure abdominal girth daily (Fig. 49.5).
9. Monitor level of consciousness; assess for precoma state (tremors, delirium).
10. Monitor for **asterixis**, a coarse tremor characterized by rapid, nonrhythmic extensions and flexions in the wrist and fingers (Fig. 49.6).

Telegram & Insta: NCLEX_RN_Edu

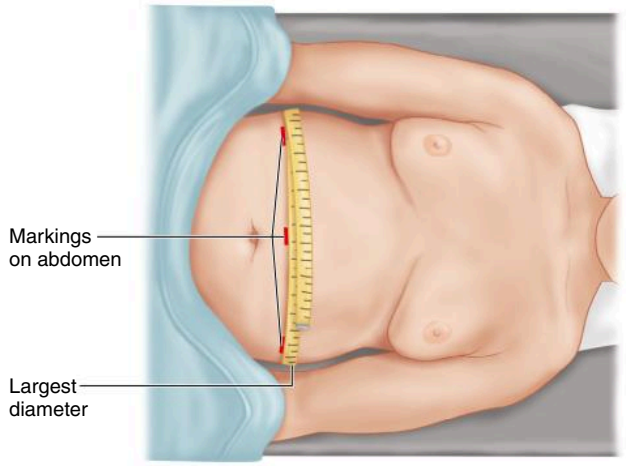

FIG. 49.5 How to measure abdominal girth. With the client supine, bring the tape measure around the client and take a measurement at the level of the umbilicus. Before removing the tape, mark the client's abdomen along the sides of tape on the client's flanks (sides) and midline to ensure that later measurements are taken at the same place.

11. Monitor for **fetor hepaticus**, the fruity, musty breath odor of severe chronic liver disease.
12. Maintain gastric intubation to assess bleeding or esophagogastric balloon tamponade to control bleeding varices as prescribed.
13. Administer blood products as prescribed.
14. Monitor coagulation laboratory results; administer vitamin K if prescribed.
15. Administer antacids as prescribed.
16. Administer lactulose as prescribed, which decreases the pH of the bowel, decreases production of ammonia by bacteria in the bowel, and facilitates the excretion of ammonia.
17. Administer antibiotics as prescribed to inhibit protein synthesis in bacteria and decrease the production of ammonia.
18. Avoid medications such as opioids, sedatives, and barbiturates and any hepatotoxic medications or substances.
19. Instruct the client about the importance of abstinence of alcohol intake.
20. Prepare the client for paracentesis to remove abdominal fluid.
21. Prepare the client for surgical shunting procedures if prescribed to divert fluid from ascites into the venous system.
22. Instruct the client on how to recognize signs of encephalopathy and to contact the primary health care provider if these signs develop.
23. Collaborate with the health care team to help the client be as independent as possible.

XIV. Esophageal Varices

A. Description
1. Dilated and tortuous veins in the submucosa of the esophagus

FIG. 49.6 Eliciting asterixis (flapping tremor). Have the client extend the arm, dorsiflex the wrist, and extend the fingers. Observe for rapid, nonrhythmic extensions and flexions.

2. Caused by portal hypertension, often associated with liver **cirrhosis**; are at high risk for rupture if portal circulation pressure rises
3. Bleeding varices are a life-threatening emergency.
4. The goal of treatment is to control bleeding, prevent complications, and prevent the recurrence of bleeding.

B. Assessment
1. Hematemesis
2. **Melena**
3. Ascites
4. Jaundice
5. Hepatomegaly and splenomegaly
6. Dilated abdominal veins
7. Signs of shock

! Rupture and resultant hemorrhage of esophageal varices are the primary concerns, because this represents a life-threatening situation.

C. Interventions
1. Monitor vital signs.
2. Elevate the head of the bed.
3. Monitor for orthostatic hypotension.
4. Monitor lung sounds and for the presence of respiratory distress.
5. Administer oxygen as prescribed to prevent tissue hypoxia.
6. Monitor level of consciousness.
7. Maintain NPO status.
8. Administer fluids intravenously as prescribed to restore fluid volume and electrolyte imbalances; monitor intake and output.
9. Monitor hemoglobin and hematocrit values and coagulation factors.
10. Administer blood transfusions or clotting factors as prescribed.
11. Assist in inserting an NG tube or a balloon tamponade as prescribed; balloon tamponade is not used frequently because it is very uncomfortable for the client and its use is associated with complications.

Telegram & Insta: NCLEX_RN_Edu

12. Prepare to assist with administering medications to induce vasoconstriction and reduce bleeding.
13. Instruct the client to avoid activities that will initiate vasovagal responses.
14. Prepare the client for endoscopic procedures or surgical procedures as prescribed.

D. Endoscopic injection (sclerotherapy)
1. The procedure involves the injection of a sclerosing agent into and around bleeding varices.
2. Complications include chest pain, pleural effusion, aspiration pneumonia, esophageal stricture, and perforation of the esophagus.

E. Endoscopic variceal ligation
1. The procedure involves ligation of the varices with an elastic rubber band.
2. Sloughing, followed by superficial ulceration, occurs in the area of ligation within 3 to 7 days.

F. Shunting procedures
1. Description: Shunt blood away from the esophageal varices
2. Portacaval shunting involves anastomosis of the portal vein to the inferior vena cava, diverting blood from the portal system to the systemic circulation.
3. Distal splenorenal shunt
   a. The shunt involves anastomosis of the splenic vein to the left renal vein.
   b. The spleen conducts blood from the high-pressure varices to the low-pressure renal vein.
4. Mesocaval shunting involves a side anastomosis of the superior mesenteric vein to the proximal end of the inferior vena cava.
5. Transjugular intrahepatic portosystemic shunt (TIPS)
   a. This procedure uses the normal vascular anatomy of the liver to create a shunt with the use of a metallic stent.
   b. The shunt is between the portal and systemic venous system in the liver and is aimed at relieving portal hypertension.
   c. It reduces portal hypertension by diverting blood flow around the liver.

XV. Hepatitis

A. Description
1. Inflammation of the liver caused by a virus, bacteria, or exposure to medications or hepatotoxins
2. The goals of treatment include resting the inflamed liver to reduce metabolic demands and increasing the blood supply, thus promoting cellular regeneration and preventing complications.
3. Hepatitis is a treatable disease in all cases. Hepatitis A and C are curable. Hepatitis A and B generally resolve without treatment or long-term liver damage although Hepatitis B is more likely to result in chronic liver dysfunction.

B. Types of **hepatitis** include hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis D virus (HDV), and hepatitis E virus (HEV).

C. Assessment and stages of viral hepatitis (Box 49.9)

BOX 49.9 Stages and Assessment of Viral Hepatitis

Preicteric Stage

The first stage of hepatitis, which begins about 2 weeks after exposure and precedes the appearance of jaundice. This stage includes flulike symptoms (malaise and fatigue), anorexia, nausea, vomiting, diarrhea, pain (such as headache, muscle aches, or polyarthritis), and elevated serum bilirubin and enzyme levels. Highly transmissible at this stage.

Icteric Stage

Begins 1 to 2 weeks after preicteric stage. The second stage of hepatitis; includes the appearance of jaundice and associated symptoms such as elevated bilirubin levels, dark or tea-colored urine, and clay-colored stools; pruritus; and a decrease in preicteric-phase symptoms. Fatigue and abdominal pain may persist or become more severe.

Posticteric Stage

Begins with the resolution of jaundice, about 6 to 8 weeks after exposure. The convalescent stage of hepatitis, in which the jaundice decreases and the color of the urine and stool returns to normal. Energy increases, pain subsides, there are minimal to absent gastrointestinal symptoms, and bilirubin and enzyme levels return to normal.

XVI. Hepatitis A

A. Description: Formerly known as *infectious hepatitis*

B. Individuals at increased risk
1. Crowded conditions (e.g., day care, nursing home)
2. Exposure to poor sanitation

C. Transmission
1. Fecal-oral route
2. Person-to-person contact
3. Parenteral
4. Contaminated fruits or vegetables, or uncooked shellfish
5. Contaminated water or milk
6. Poorly washed utensils

D. Incubation and infectious period
1. Incubation period is 15 to 50 days.
2. Infectious period is 2 to 3 weeks before and 1 week after development of jaundice.

E. Testing
1. Infection is established by the presence of HAV antibodies (anti-HAV) in the blood.

Telegram & Insta: NCLEX_RN_Edu

2. Immunoglobulin M (IgM) and immunoglobulin G (IgG) are normally present in the blood, and increased levels indicate infection and inflammation.
3. Ongoing inflammation of the liver is evidenced by the presence of elevated levels of IgM antibodies, which persist in the blood for 4 to 6 weeks.
4. Previous infection is indicated by the presence of elevated levels of IgG antibodies.

F. Complication: Fulminant (severe acute and often fatal) hepatitis

G. Prevention
1. Strict handwashing, especially after handling shellfish
2. Avoid contaminated food.
3. Stool and needle precautions
4. Treatment of municipal water supplies
5. Serological screening of food handlers
6. Hepatitis A vaccine: Two doses are needed at least 6 months apart for lasting protection. For additional information, refer to http://www.cdc.gov/vaccines/hcp/vis/vis-statements/hep-a.html
7. Immune globulin: For individuals exposed to HAV who have never received the hepatitis A vaccine; administer immune globulin during the period of incubation and within 2 weeks of exposure.
8. Immune globulin and hepatitis A vaccine are recommended for household members and sexual contacts of individuals with hepatitis A.
9. Preexposure prophylaxis with immune globulin is recommended to individuals traveling to countries with poor or uncertain sanitation conditions.

Strict and frequent handwashing is key to preventing the spread of all types of hepatitis.

XVII. Hepatitis B

A. Description
1. Hepatitis B is nonseasonal.
2. All age-groups can be affected.

B. Individuals at increased risk
1. IV drug users
2. Clients undergoing long-term hemodialysis
3. Health care personnel

C. Transmission
1. Blood or body fluid contact
2. Infected blood products
3. Infected saliva or semen
4. Contaminated needles
5. Sexual contact
6. Parenteral
7. Perinatal period
8. Blood or body fluid contact at birth
9. Hemodialysis
10. Sharing razors or toothbrushes with an infected individual

D. Incubation period: 60 to 180 days

E. Testing
1. Infection is established by the presence of hepatitis B antigen–antibody systems in the blood.
2. The presence of hepatitis B surface antigen (HBsAg) is the serological marker establishing the diagnosis of hepatitis B.
3. The client is considered infectious if these antigens are present in the blood.
4. If the serological marker (HBsAg) is present after 6 months, it indicates a carrier state or chronic hepatitis.
5. Normally, the serological marker (HBsAg) level declines and disappears after the acute hepatitis B episode.
6. The presence of antibodies to HBsAg (anti-HBs) indicates recovery and immunity to hepatitis B.
7. Hepatitis B early antigen (HBeAg) is detected in the blood about 1 week after the appearance of HBsAg, and its presence determines the infective state of the client.

F. Complications
1. Fulminant hepatitis
2. Chronic liver disease
3. Cirrhosis
4. Primary hepatocellular carcinoma

G. Prevention
1. Strict handwashing
2. Screening blood donors
3. Testing of all pregnant individuals
4. Needle precautions
5. Avoiding intimate sexual contact and contact with body fluids if test for HBsAg is positive.
6. Hepatitis B vaccine: Adult and pediatric forms; there is also an adult vaccine that protects against hepatitis A and B.
7. Hepatitis B immune globulin is for individuals exposed to HBV through sexual contact or through the percutaneous or transmucosal routes who have never had hepatitis B and have never received hepatitis B vaccine.

XVIII. Hepatitis C

A. Description
1. HCV infection occurs year-round.
2. Infection can occur in any age-group.
3. Infection with HCV is common among IV drug users and is the major cause of posttransfusion hepatitis.
4. Risk factors are similar to those for HBV, because hepatitis C is also transmitted parenterally.

B. Individuals at increased risk
1. Parenteral drug users
2. Clients receiving frequent transfusions
3. Health care personnel
4. Those born between 1945 and 1965
5. Prisoners

Telegram & Insta: NCLEX_RN_Edu

C. Transmission: Same as for HBV, primarily through blood
D. Incubation period: 2 weeks to 6 months
E. Testing: Anti-HCV is the antibody to HCV and is measured to detect chronic states of hepatitis C.
F. Complications
   1. Chronic liver disease
   2. Cirrhosis
   3. Primary hepatocellular carcinoma
G. Prevention
   1. Strict handwashing
   2. Needle precautions
   3. Screening of blood donors

XIX. Hepatitis D

A. Description
   1. Hepatitis D is common in the Mediterranean and Middle Eastern areas.
   2. Hepatitis D occurs with hepatitis B and causes infection only in the presence of active HBV infection.
   3. Coinfection with the delta agent (HDV) intensifies the acute symptoms of hepatitis B.
   4. Transmission and risk of infection are the same as for HBV, via contact with blood and blood products.
   5. Prevention of HBV infection with vaccine also prevents HDV infection, because HDV depends on HBV for replication.
B. High-risk individuals
   1. Drug users
   2. Clients receiving hemodialysis
   3. Clients receiving frequent blood transfusions
C. Transmission: Same as for HBV
D. Incubation period: 2 to 26 weeks
E. Testing: Serological HDV determination is made by detection of the hepatitis D antigen (HDAg) early in the course of the infection and by detection of anti-HDV antibody in the later disease stages.
F. Complications
   1. Chronic liver disease
   2. Fulminant hepatitis
G. Prevention: Because hepatitis D must coexist with hepatitis B, the precautions that help prevent hepatitis B are also useful in preventing delta hepatitis.

XX. Hepatitis E

A. Description
   1. Hepatitis E is a waterborne virus.
   2. Hepatitis E is prevalent in areas where sewage disposal is inadequate or where communal bathing in contaminated rivers is practiced.
   3. Risk of infection is the same as for HAV.
   4. Infection with HEV presents as a mild disease except in infected individuals in the third trimester of pregnancy, who have a high mortality rate.
B. Individuals with increased risk
   1. Travelers to countries that have a high incidence of hepatitis E, such as India, Burma (Myanmar), Afghanistan, Algeria, and Mexico
   2. Eating or drinking of food or water contaminated with the virus
C. Transmission: Same as for HAV
D. Incubation period: 2 to 9 weeks
E. Testing: Specific serological tests for HEV include detection of IgM and IgG antibodies to hepatitis E (anti-HEV).
F. Complications
   1. High mortality rate in pregnant individuals
   2. Fetal demise
G. Prevention
   1. Strict handwashing
   2. Treatment of water supplies and sanitation measures

XXI. Client and Family Home Care Instructions for Hepatitis: See Box 49.10

BOX 49.10 Home Care Instructions for the Client with Hepatitis

- Handwashing must be strict and frequent.
- Do not share bathrooms unless the client strictly adheres to personal hygiene measures.
- Individual washcloths, towels, drinking and eating utensils, and toothbrushes and razors must be labeled and used only by the client.
- The client must not prepare food for other family members.
- The client should avoid alcohol and over-the-counter medications, particularly acetaminophen and sedatives, because these medications are hepatotoxic.
- The client should increase activity gradually to prevent fatigue.
- The client should consume small, frequent meals consisting of high-carbohydrate, low-fat foods.
- The client is not to donate blood.
- The client may maintain normal contact with persons as long as proper personal hygiene is maintained, but crowds should be avoided.
- Close personal contact such as kissing and sexual activity should be discouraged with hepatitis B until surface antigen test results are negative.
- Plan frequent rest periods.
- The client needs to carry a MedicAlert card noting the date of hepatitis onset.
- The client needs to inform other health professionals, such as medical or dental personnel, of the onset of hepatitis.
- The client needs to keep follow-up appointments with the primary health care provider, and should check before taking any medications, vitamins, supplements, or herbal preparations.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for inter-professional collaborative care*. (10th ed.). St. Louis: Saunders. p.1168, 1170-1171.

Telegram & Insta: NCLEX_RN_Edu

XXII. Pancreatitis

A. Description

1. Acute or chronic inflammation of the pancreas, with associated escape of pancreatic enzymes into surrounding tissue

2. Acute pancreatitis occurs suddenly as one attack or can be recurrent, with resolutions.

3. Chronic pancreatitis is a continual inflammation and destruction of the pancreas, with scar tissue replacing pancreatic tissue.

4. Precipitating factors include trauma, the use of alcohol, biliary tract disease, viral or bacterial disease, hyperlipidemia, hypercalcemia, cholelithiasis, hyperparathyroidism, ischemic vascular disease, and peptic ulcer disease.

B. Acute pancreatitis

1. Assessment

a. Abdominal pain, including a sudden onset at a midepigastric or left upper quadrant location with radiation to the back

b. Pain aggravated by a fatty meal, alcohol, or lying in a recumbent position

c. Restlessness, anxiety, low-grade fever

d. Abdominal tenderness, distention, and guarding

e. Nausea and vomiting

f. Weight loss

g. Absent or decreased bowel sounds

h. Elevated white blood cell count and elevated glucose, bilirubin, alkaline phosphatase, and urinary amylase levels

i. Elevated serum lipase and amylase levels

j. Cullen's sign

k. Turner's sign

Cullen's sign is the discoloration of the abdomen and periumbilical area. Turner's sign is the bluish discoloration of the flanks. Both signs are indicative of pancreatitis.

2. Interventions

a. Withhold food and fluid during the acute period, and maintain hydration with IV fluids as prescribed.

b. Administer parenteral nutrition for severe nutritional depletion.

c. Administer supplemental preparations and vitamins and minerals to increase caloric intake if prescribed.

d. An NG tube may be inserted if the client is vomiting or has biliary obstruction or paralytic ileus.

e. Acute pancreatitis may require feeding if prolonged NPO status remains. For feeding, will need to place a nasojejunal tube past the ligament of Treitz.

f. Administer opiates as prescribed for pain.

g. Administer H_2-receptor antagonists or proton pump inhibitors as prescribed to decrease hydrochloric acid production and prevent activation of pancreatic enzymes.

h. Monitor for significant changes in vital signs that may indicate the life-threatening complication of shock.

i. Observe for changes in behavior and level of consciousness that may be related to alcohol withdrawal, hypoxia, or impending sepsis with shock.

j. Instruct the client in the importance of avoiding alcohol.

k. Instruct the client in the importance of follow-up visits with the PHCP.

l. Instruct the client to notify the PHCP if acute abdominal pain, jaundice, clay-colored stools, or dark-colored urine develops.

C. Chronic pancreatitis

1. Assessment

a. Abdominal pain and tenderness

b. Left upper quadrant mass

c. Steatorrhea and foul-smelling stools that may increase in volume as pancreatic insufficiency increases

d. Weight loss

e. Muscle wasting

f. Jaundice

g. Ascites

h. Signs and symptoms of diabetes mellitus

i. Signs and symptoms of respiratory compromise manifesting with adventitious or diminished breath sounds, dyspnea, or orthopnea

2. Interventions

a. Instruct the client in the prescribed dietary measures (fat and protein intake may be limited).

b. Instruct the client to avoid heavy meals.

c. Instruct the client about the importance of avoiding alcohol and avoiding caffeinated beverages.

d. Provide supplemental preparations and vitamins and minerals to increase caloric intake; instruct the client to eat small meals and snacks high in calories.

e. Administer pancreatic enzymes as prescribed to aid in the digestion and absorption of fat and protein.

f. Administer insulin or oral hypoglycemic medications as prescribed to control diabetes mellitus, if present.

g. Instruct the client in the use of pancreatic enzyme medications.

h. Instruct the client in the treatment plan for glucose management.

i. Instruct the client to notify the PHCP if increased steatorrhea, abdominal distention or cramping, or skin breakdown develops.

Telegram & Insta: NCLEX_RN_Edu

j. Instruct the client to restrict activity to one floor until strength is regained. Emphasize the importance of follow-up visits.

XXIII. Pancreatic Tumors, Intestinal Tumors, and Bowel Obstructions: See Chapter 45 for more information.

XXIV. Irritable Bowel Syndrome (IBS)

A. Description
1. Functional disorder characterized by chronic or recurrent diarrhea, constipation, and/or abdominal pain and bloating
2. Cause is unclear but may be influenced by environmental, immunological, genetic, hormonal, and stress factors

B. Interventions
1. Increase dietary fiber.
2. Drink 8 to 10 cups of liquids per day.
3. Medication therapy: Depends on the predominant symptoms of IBS (antidiarrheals versus bulk-forming laxatives; lubiprostone or linaclotide for constipation-predominant IBS and alosetron for diarrhea-predominant IBS)
4. Probiotic supplements may be recommended.

XXV. Ulcerative Colitis

A. Description
1. An ulcerative and inflammatory disease of the bowel that results in poor absorption of nutrients
2. Commonly begins in the rectum and spreads upward toward the cecum
3. The colon becomes edematous and may develop bleeding lesions and ulcers; the ulcers may lead to perforation.
4. Scar tissue develops and causes loss of elasticity and loss of the ability to absorb nutrients.
5. Colitis is characterized by various periods of remissions and exacerbations.
6. Acute ulcerative colitis results in vascular congestion, hemorrhage, edema, and ulceration of the bowel mucosa.
7. Chronic ulcerative colitis causes muscular hypertrophy, fat deposits, and fibrous tissue, with bowel thickening, shortening, and narrowing.

B. Assessment
1. Anorexia
2. Weight loss
3. Malaise
4. Abdominal tenderness and cramping
5. Severe diarrhea that may contain blood and mucus
6. Malnutrition, dehydration, and electrolyte imbalances
7. Anemia
8. Vitamin K deficiency
9. Intermittent fever

C. Interventions
1. Acute phase: Maintain NPO status, and administer fluids and electrolytes intravenously or via parenteral nutrition as prescribed.
2. Restrict the client's activity to reduce intestinal activity.
3. Monitor bowel sounds and for abdominal tenderness and cramping.
4. Monitor stools, noting color, consistency, and the presence or absence of blood.
5. Monitor for bowel perforation, peritonitis (see Box 49.3), and hemorrhage.
6. Monitor daily weight, serum electrolytes, complete blood count, and vital signs.
7. Following the acute phase, the diet progresses from clear liquids to a low-fiber diet as prescribed and tolerated.
8. Instruct the client about diet. Usually a low-fiber diet is prescribed during an exacerbation episode; in addition, a high-protein diet with vitamins and iron supplements is prescribed.
9. Instruct the client to avoid gas-forming foods, milk products, and foods such as whole-wheat grains, nuts, raw fruits and vegetables, pepper, alcohol, and caffeine-containing products.
10. Instruct the client to avoid smoking.
11. Encourage the client to schedule activities around rest periods.
12. Administer medications as prescribed, which may include a combination of medications such as salicylate compounds, corticosteroids, immunosuppressants, and antidiarrheals.

D. Surgical interventions
1. Performed in extreme cases if medical management is unsuccessful
2. Minimally invasive procedures are considered as a surgical option if the client is a candidate; clients who are obese, have had previous abdominal surgeries, or have adhesions may not be candidates.
3. Minimally invasive procedures can include laparoscopic procedures, robotic-assisted surgery, and natural orifice transluminal endoscopic surgery (NOTES).
4. Restorative proctocolectomy with ileal pouch–anal anastomosis (RPC-IPAA)
   a. Allows for bowel continence
   b. May be performed through laparoscopic procedure
   c. Involves a two-stage procedure that includes removal of the colon and most of the rectum; the anus and anal sphincter remain intact.
   d. An internal pouch known as a reservoir (J-pouch, S-pouch, or pelvic pouch) is created using the small intestine and connected to the anus, followed by creation of a temporary ileostomy through the abdominal skin

Telegram & Insta: NCLEX_RN_Edu

to allow healing of the internal pouch and all anastomosis sites.

e. In the second surgical procedure (within 1 to 2 months), the ileostomy is closed.

5. Total proctocolectomy with permanent ileostomy

a. Performed if the client is not a candidate for RPC-IPAA or if the client prefers this type of procedure

b. The procedure involves the removal of the entire colon (colon, rectum, and anus, with anal closure).

c. The end of the terminal ileum forms the stoma or ostomy, which is located in the right lower quadrant.

6. Preoperative interventions

a. Informed consent needs to be obtained.

b. Consult with the enterostomal therapist to help identify optimal placement of the ostomy.

c. Instruct the client on dietary restrictions; the client may need to follow a low-fiber diet for 1 to 2 days before surgery.

d. Parenteral antibiotics are administered 1 hour before the surgical opening.

e. Address body image concerns, and allow the client to express concerns; a visit from an ostomate may be helpful to the client.

7. Postoperative interventions

a. A pouch system with a skin barrier is usually placed on the stoma postoperatively; if a pouch system is not covering the stoma, a petrolatum gauze dressing is placed over the stoma as prescribed to keep it moist, followed by a dry sterile dressing.

b. Monitor the stoma for size, unusual bleeding, or necrotic tissue.

c. Monitor for color changes in the stoma.

d. Note that the normal stoma color is pink to bright red and shiny, indicating high vascularity.

e. Note that a pale pink stoma indicates low hemoglobin and hematocrit levels and a purple-black stoma indicates compromised circulation, requiring PHCP notification.

f. Assess the functioning of the ostomy.

g. Expect that stool is liquid in the immediate postoperative period but becomes more solid depending on the area of creation—ascending colon, liquid; transverse colon, loose to semiformed; and descending colon, close to normal.

h. Monitor the pouch system for proper fit and signs of leakage; the pouch is emptied when it is one-third full.

i. Fecal matter should not be allowed to remain on the skin; skin assessment and care are a priority.

j. Monitor for dehydration and electrolyte imbalance.

k. Administer analgesics and antibiotics as prescribed.

l. Instruct the client to avoid foods that cause excess gas formation and odor, and to eliminate foods that are not digested well, such as nuts and corn.

m. Instruct the client about stoma care and irrigations if prescribed (see Chapter 17, Box 17.8, for colostomy irrigation procedure).

n. Instruct the client that normal activities may be resumed when approved by the PHCP.

! A stoma that is purple-black in color indicates compromised circulation, requiring immediate PHCP notification.

XXVI. Crohn's Disease

A. Description

1. An inflammatory disease that can occur anywhere in the gastrointestinal tract but most often affects the terminal ileum and leads to thickening and scarring, a narrowed lumen, fistulas, ulcerations, and abscesses

2. Characterized by remissions and exacerbations

B. Assessment

1. Fever

2. Cramplike and colicky pain after meals

3. Diarrhea (semisolid), which may contain mucus, pus, or the presence of blood in the stool

4. Abdominal pain and distention

5. Anorexia, nausea, and vomiting

6. Weight loss

7. Anemia

8. Dehydration

9. Electrolyte imbalances

10. Malnutrition (may be worse than that seen in ulcerative colitis)

C. Interventions: Care is similar to that for the client with ulcerative colitis; however, surgery may be necessary but is avoided for as long as possible because recurrence of the disease process in the same region is likely to occur.

D. Monitor for signs and symptoms of peritonitis, bowel obstruction, and nutritional and fluid imbalances; early detection of a change in the client's status will help reduce life-threatening complications.

XXVII. Appendicitis

A. Description

1. Inflammation of the appendix

2. When the appendix becomes inflamed or infected, rupture may occur within a matter of hours, leading to peritonitis and sepsis.

B. Assessment

1. Pain in the periumbilical area that descends to the right lower quadrant

Telegram & Insta: NCLEX_RN_Edu

2. Abdominal pain that is most intense at McBurney's point
3. Rebound tenderness and abdominal rigidity
4. Low-grade fever
5. Elevated white blood cell count
6. Anorexia, nausea, and vomiting
7. Client in side-lying position, with abdominal guarding and legs flexed
8. Constipation or diarrhea

C. Peritonitis: Inflammation of the peritoneum (see Box 49.3)

D. Appendectomy: Surgical removal of the appendix

1. Preoperative interventions
   a. Informed consent needs to be obtained.
   b. Maintain NPO status.
   c. Administer fluids intravenously to prevent dehydration.
   d. Monitor for changes in level of pain.
   e. Monitor for signs of ruptured appendix and peritonitis (see Box 49.3).
   f. Position the client in a right side–lying or low to semi-Fowler's position to promote comfort.
   g. Monitor bowel sounds.
   h. Apply ice packs to the abdomen for 20 to 30 minutes every hour if prescribed.
   i. Administer antibiotics as prescribed.
   j. Avoid laxatives or enemas.

⚠ Avoid the application of heat to the abdomen of a client with appendicitis. Heat can cause rupture of the appendix, leading to peritonitis, a life-threatening condition.

2. Postoperative interventions
   a. Monitor temperature for signs of infection.
   b. Assess incision for signs of infection such as redness, swelling, and pain.
   c. Maintain NPO status until bowel function has returned.
   d. Advance diet gradually as tolerated and as prescribed, when bowel sounds return.
   e. If rupture of the appendix occurred, expect a drain to be inserted, or the incision may be left open to heal from the inside out.
   f. Expect that drainage from the drain may be profuse for the first 12 hours.
   g. Position the client in a right side–lying or low to semi-Fowler's position, with legs flexed, to facilitate drainage.
   h. Change the dressing as prescribed, and record the type and amount of drainage.
   i. Perform wound irrigations if prescribed.
   j. Maintain NG suction and patency of the NG tube if present.
   k. Administer antibiotics and analgesics as prescribed.
   l. Help the client to get out of bed a few hours after surgery to help prevent respiratory complications, such as atelectasis.

XXVIII. Diverticulosis and Diverticulitis

A. Description

1. Diverticulosis
   a. **Diverticulosis** is an outpouching or herniation of the intestinal mucosa.
   b. The disorder can occur in any part of the intestine but is most common in the sigmoid colon.
2. Diverticulitis
   a. **Diverticulitis** is the inflammation of one or more diverticula that occurs from penetration of fecal matter through the thin-walled diverticula; it can result in local abscess formation and perforation.
   b. A perforated diverticulum can progress to intra-abdominal perforation with generalized peritonitis.

B. Assessment

1. Left lower quadrant abdominal pain that increases with coughing, straining, or lifting
2. Elevated temperature
3. Nausea and vomiting
4. Flatulence
5. Cramplike pain
6. Abdominal distention and tenderness
7. Palpable, tender rectal mass may be present.
8. Blood in the stools

C. Interventions

1. Provide bed rest during the acute phase.
2. Maintain NPO status or provide clear liquids during the acute phase as prescribed.
3. When the diverticulitis is active, provide a low-fiber diet; when the inflammation resolves, provide a high-fiber diet.
4. Administer antibiotics, analgesics, and anticholinergics to reduce bowel spasms as prescribed.
5. Instruct the client to refrain from lifting, straining, coughing, and bending to avoid increased intra-abdominal pressure, and to avoid wearing tight restrictive clothing.
6. Monitor for perforation (see Box 49.3), hemorrhage, fistulas, and abscesses.
7. Abdominal x-rays may be done to evaluate for free air and fluid, indicating perforation.
8. Instruct the client to increase fluid intake to 2500 to 3000 mL daily, unless contraindicated.
9. Instruct the client to eat soft high-fiber foods, such as whole grains; the client should avoid high-fiber foods when inflammation occurs, because these foods will irritate the mucosa further.
10. Instruct the client to avoid gas-forming foods or foods containing indigestible roughage, seeds, nuts, or popcorn, because these food substances become trapped in diverticula and cause inflammation.
11. Instruct the client to consume a small amount of bran daily and to take bulk-forming laxatives as prescribed to increase stool mass.

Telegram & Insta: NCLEX_RN_Edu

12. Instruct on the importance of avoiding the use of laxatives or enemas unless prescribed.

D. Surgical interventions
1. Colon resection with primary anastomosis may be an option.
2. Temporary or permanent colostomy may be required for increased bowel inflammation.

XXIX. Hemorrhoids

A. Description
1. Dilated varicose veins of the anal canal
2. May be internal, external, or prolapsed
3. Internal hemorrhoids lie above the anal sphincter and cannot be seen on inspection of the perianal area.
4. External hemorrhoids lie below the anal sphincter and can be seen on inspection.
5. Prolapsed hemorrhoids can become thrombosed or inflamed.
6. Hemorrhoids are caused from portal hypertension, straining, irritation, or increased venous or abdominal pressure.

B. Assessment
1. Bright red bleeding with defecation
2. Rectal pain
3. Rectal itching

C. Interventions
1. Apply cold packs to the anal-rectal area followed by sitz baths as prescribed.
2. Apply witch hazel soaks and topical anesthetics as prescribed.
3. Encourage a high-fiber diet and fluids to promote bowel movements without straining.
4. Administer stool softeners as prescribed.
5. Encourage the client to drink plenty of water unless contraindicated.
6. Encourage regular exercise, maintenance of a healthy weight, and a diet high in fiber and fluids to promote regular bowel movements without straining.

D. Surgical interventions: May include ultrasound, sclerotherapy, circular stapling, band ligation, or simple resection of the hemorrhoids (hemorrhoidectomy)

E. Postoperative interventions following hemorrhoidectomy
1. Assist the client to a prone or side-lying position to prevent bleeding.
2. Maintain ice packs over the dressing as prescribed until the packing is removed by the PHCP.
3. Monitor for urinary retention.
4. Administer stool softeners as prescribed.
5. Instruct the client to increase fluids and high-fiber foods.
6. Instruct the client to limit sitting to short periods of time.
7. Instruct the client that the first bowel movement may be very painful; be sure someone is nearby as the client can become light-headed, diaphoretic, or experience syncope from a vasovagal response.
8. Instruct the client in the use of sitz baths three or four times a day as prescribed.

PRACTICE QUESTIONS

1. The nurse is monitoring a client admitted to the hospital with a diagnosis of appendicitis who is scheduled for surgery in 2 hours. The client begins to complain of increased abdominal pain and begins to vomit. On assessment, the nurse notes that the abdomen is distended and bowel sounds are diminished. Which is the **most appropriate** nursing intervention?
1. Notify the surgeon.
2. Administer the prescribed pain medication.
3. Call and ask the operating room team to perform surgery as soon as possible.
4. Reposition the client and apply a heating pad on the warm setting to the client's abdomen.

2. A client admitted to the hospital with a suspected diagnosis of acute pancreatitis is being assessed by the nurse. Which assessment findings would be consistent with acute pancreatitis? **Select all that apply.**
❑ 1. Diarrhea
❑ 2. Black, tarry stools
❑ 3. Hyperactive bowel sounds
❑ 4. Gray-blue color at the flank
❑ 5. Abdominal guarding and tenderness
❑ 6. Left upper quadrant pain with radiation to the back

3. The nurse is assessing a client who is experiencing an acute episode of cholecystitis. Which of these clinical manifestations support this diagnosis? **Select all that apply.**
❑ 1. Fever
❑ 2. Positive Cullen's sign
❑ 3. Complaints of indigestion
❑ 4. Palpable mass in the left upper quadrant
❑ 5. Pain in the upper right quadrant after a fatty meal
❑ 6. Vague lower right quadrant abdominal discomfort

4. A client diagnosed with viral hepatitis is complaining of "no appetite" and "losing my taste for food." What instruction would the nurse give the client to provide adequate nutrition?
1. Select foods high in fat.
2. Increase intake of fluids, including juices.
3. Eat a good supper, when anorexia is less severe.
4. Eat less often, preferably only three large meals daily.

Telegram & Insta: NCLEX_RN_Edu

5. A client has developed hepatitis A after eating contaminated oysters. The nurse assesses the client for which expected assessment finding?
   1. Malaise
   2. Dark stools
   3. Weight gain
   4. Left upper quadrant discomfort

6. A client has just had a hemorrhoidectomy. Which nursing interventions are appropriate for this client? **Select all that apply.**
   - ❑ 1. Administer stool softeners as prescribed.
   - ❑ 2. Instruct the client to limit fluid intake to avoid urinary retention.
   - ❑ 3. Encourage a high-fiber diet to promote bowel movements without straining.
   - ❑ 4. Apply cold packs to the anal-rectal area over the dressing until the packing is removed.
   - ❑ 5. Help the client to a Fowler's position to place pressure on the rectal area and decrease bleeding.

7. The nurse is planning to teach a client with gastroesophageal reflux disease (GERD) about substances to avoid. Which items would the nurse include on this list? **Select all that apply.**
   - ❑ 1. Coffee
   - ❑ 2. Chocolate
   - ❑ 3. Peppermint
   - ❑ 4. Nonfat milk
   - ❑ 5. Fried chicken
   - ❑ 6. Scrambled eggs

8. A client suspected of having a duodenal ulcer has undergone esophagogastroduodenoscopy. The nurse would place **highest priority** on which item as part of the client's care plan?
   1. Monitoring the temperature
   2. Monitoring complaints of heartburn
   3. Giving warm gargles for a sore throat
   4. Assessing for the return of the gag reflex

9. The nurse has taught the client with suspected gallbladder disease about an upcoming endoscopic retrograde cholangiopancreatography (ERCP) procedure. The nurse determines that the client **needs further information** if the client makes which statement?
   1. "I know I must sign the consent form."
   2. "I hope the throat spray keeps me from gagging."
   3. "I'm glad I don't have to lie still for this procedure."
   4. "I'm glad some intravenous medication will be given to relax me."

10. The primary health care provider has determined that a client has contracted hepatitis A based on flulike symptoms and jaundice. Which statement made by the client supports this medical diagnosis?
    1. "I have had unprotected sex with multiple partners."
    2. "I ate shellfish about 2 weeks ago at a local restaurant."
    3. "I was an intravenous drug abuser in the past and shared needles."
    4. "I had a blood transfusion 30 years ago after major abdominal surgery."

11. The nurse is assessing a client 24 hours after a cholecystectomy. The nurse notes that the T-tube has drained 750 mL of green-brown drainage since the surgery. Which nursing intervention is **most appropriate**?
    1. Clamp the T-tube.
    2. Irrigate the T-tube.
    3. Notify the surgeon.
    4. Document the findings.

12. The nurse is monitoring a client with a diagnosis of peptic ulcer. Which assessment finding would **most likely** indicate perforation of the ulcer?
    1. Bradycardia
    2. Numbness in the legs
    3. Nausea and vomiting
    4. A rigid, boardlike abdomen

13. A client with severe ulcer disease in the distal stomach undergoes a gastrojejunostomy (Billroth II procedure). Which postoperative prescription would the nurse question and verify?
    1. Leg exercises
    2. Early ambulation
    3. Irrigating the nasogastric tube
    4. Coughing and deep-breathing exercises

14. The nurse is providing discharge instructions to a client following gastrectomy and would instruct the client to take which measure to assist in preventing dumping syndrome?
    1. Ambulate following a meal.
    2. Limit the fluids taken with meals.
    3. Eat cakes and pastries only if they are homemade.
    4. Eat three meals a day rather than small frequent meals.

Telegram & Insta: NCLEX_RN_Edu

15. The nurse is reviewing the prescription for a client admitted to the hospital with a diagnosis of acute pancreatitis. Which interventions would the nurse expect to be prescribed for the client? **Select all that apply.**

- ❑ 1. Maintain NPO (nothing by mouth) status.
- ❑ 2. Encourage coughing and deep breathing.
- ❑ 3. Give small, frequent high-calorie feedings.
- ❑ 4. Maintain the client in a supine and flat position.
- ❑ 5. Give hydromorphone intravenously as prescribed for pain.
- ❑ 6. Maintain intravenous fluids at 10 mL/hr to keep the vein open.

16. The nurse is providing discharge teaching for a client with newly diagnosed Crohn's disease about dietary measures to implement during exacerbation episodes. Which statement made by the client indicates a **need for further instruction**?

1. "I need to increase the fiber in my diet."
2. "I will need to avoid caffeinated beverages."
3. "I'm going to learn some stress-reduction techniques."
4. "I can have exacerbations and remissions with Crohn's disease."

17. The nurse is reviewing the record of a client with a diagnosis of cirrhosis and notes that there is documentation of the presence of asterixis. How would the nurse assess for its presence?

1. Dorsiflex the client's foot.
2. Measure the abdominal girth.
3. Ask the client to extend the arms.
4. Instruct the client to lean forward.

18. The nurse is reviewing the laboratory results for a client with cirrhosis and notes that the ammonia level is 85 mcg/dL (51 mcmol/L). Which dietary selection does the nurse suggest to the client?

1. Roast pork
2. Cheese omelet
3. Pasta with sauce
4. Tuna fish sandwich

19. The nurse is doing an admission assessment on a client with a history of duodenal ulcer. To determine whether the problem is currently active, the nurse would assess the client for which manifestation of duodenal ulcer?

1. Weight loss
2. Nausea and vomiting
3. Pain relieved by food intake
4. Pain radiating down the right arm

20. A client with hiatal hernia chronically experiences heartburn following meals. The nurse would plan to teach the client to avoid which action because it is contraindicated with a hiatal hernia?

1. Lying recumbent following meals
2. Consuming small, frequent bland meals
3. Taking H_2-receptor antagonist medication
4. Raising the head of the bed on 6-inch (15 cm) blocks

21. The nurse is providing care for a client with a bowel obstruction who had a transverse colostomy created. Which observation requires **immediate** notification of the primary health care provider?

1. Stoma is beefy red and shiny
2. Purple discoloration of the stoma
3. Skin excoriation around the stoma
4. Semiformed stool noted in the ostomy pouch

22. A client had a new colostomy created 2 days earlier and is beginning to pass malodorous flatus from the stoma. What is the correct interpretation by the nurse?

1. This is a normal, expected event.
2. The client is experiencing early signs of ischemic bowel.
3. The client should not have the nasogastric tube removed.
4. This indicates inadequate preoperative bowel preparation.

23. A client with severe Crohn's disease has just had surgery to create an ileostomy. The nurse assesses the client in the immediate postoperative period for which **most** frequent complication of this type of surgery?

1. Folate deficiency
2. Malabsorption of fat
3. Intestinal obstruction
4. Fluid and electrolyte imbalance

24. The nurse provides instructions to a client about measures to treat irritable bowel syndrome (IBS). Which statement by the client indicates a **need for further teaching**?

1. "I need to limit my intake of dietary fiber."
2. "I need to drink plenty, at least 8 to 10 cups daily."
3. "I need to eat regular meals and chew my food well."
4. "I will take the prescribed medications because they will regulate my bowel patterns."

25. The nurse is monitoring a client for the **early** signs and symptoms of dumping syndrome. Which findings indicate this occurrence?

1. Sweating and pallor
2. Bradycardia and indigestion
3. Double vision and chest pain
4. Abdominal cramping and pain

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 1

Rationale: On the basis of the signs and symptoms presented in the question, the nurse would suspect peritonitis and notify the surgeon. Administering pain medication is not an appropriate intervention. Heat would never be applied to the abdomen of a client with suspected appendicitis because of the risk of rupture. Scheduling surgical time is not within the scope of nursing practice, although the surgeon probably would perform the surgery earlier than the prescheduled time.

Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Determine if an **abnormality exists,** focus on the signs and symptoms in the question, and consider the complications that can occur with appendicitis. Noting that the signs presented in the question indicate a complication will assist in directing you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 937-938.

2. *Answer:* 4, 5, 6

Rationale: Grayish-blue discoloration at the flank is known as Turner's sign and occurs as a result of pancreatic enzyme leakage to cutaneous tissue from the peritoneal cavity. The client may demonstrate abdominal guarding and may complain of tenderness with palpation. The pain associated with acute pancreatitis is often sudden in onset and is located in the epigastric region or left upper quadrant with radiation to the back. The other options are incorrect.

Test-Taking Strategy: Noting that options 1 and 3 are **comparable or alike** will assist you in eliminating these options first. Then recall that black, tarry stools occur when there is gastrointestinal bleeding, so this can also be eliminated. From the remaining options, recall the anatomical location of the pancreas, the pain characteristics, and the effect of enzymes leaking into the tissues to direct you to the correct options.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1185.

3. *Answer:* 1, 3, 5

Rationale: During an acute episode of cholecystitis, the client may complain of severe right upper quadrant pain that radiates to the right scapula or shoulder or experience epigastric pain after a fatty or high-volume meal. Fever and signs of dehydration would also be expected, as well as complaints of indigestion, belching, flatulence, nausea, and vomiting. Options 4 and 6 are incorrect because they are inconsistent with the anatomical location of the gallbladder. Option 2 (Cullen's sign) is associated with pancreatitis.

Test-Taking Strategy: Focus on the **subject,** the location and characteristics of pain associated with cholecystitis. Recalling the anatomical location of the gallbladder will also direct you to the correct option.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1178-1179.

4. *Answer:* 2

Rationale: Although no special diet is required to treat viral hepatitis, it is generally recommended that clients consume a low-fat diet, as fat may be tolerated poorly because of decreased bile production. Small, frequent meals are preferable and may even prevent nausea. Frequently, appetite is better in the morning, so it is easier to eat a good breakfast. An adequate fluid intake of 2500 to 3000 mL/day that includes nutritional juices is also important.

Test-Taking Strategy: Focus on the **subject,** a diet for viral hepatitis. Think about the pathophysiology associated with hepatitis, and focus on the client's complaints to direct you to the correct option.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1170.

5. *Answer:* 1

Rationale: Hepatitis causes gastrointestinal symptoms such as anorexia, nausea, right upper quadrant discomfort, and weight loss. Fatigue and malaise are common. Stools will be light- or clay-colored if conjugated bilirubin is unable to flow out of the liver because of inflammation or obstruction of the bile ducts.

Test-Taking Strategy: Focus on the **subject,** expected assessment findings. Recalling the function of the liver will direct you to the correct option. Remember that fatigue and malaise are common.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1169.

6. *Answer:* 1, 3, 4

Rationale: Nursing interventions after a hemorrhoidectomy are aimed at management of pain and avoidance of bleeding and incision rupture. Stool softeners and a high-fiber diet will help the client avoid straining, thereby reducing the chances of rupturing the incision. An ice pack will increase comfort and decrease bleeding. Options 2 and 5 are incorrect interventions.

Test-Taking Strategy: Focus on the **subject,** postoperative hemorrhoidectomy care. Recall that decreasing fluid intake will cause difficulty with defecation because of hard stool. Recognize that Fowler's position will increase pressure in the rectal area, causing increased bleeding and increased pain.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1128.

7. *Answer:* 1, 2, 3, 5

Rationale: Foods that decrease lower esophageal sphincter (LES) pressure and irritate the esophagus will increase reflux and exacerbate the symptoms of GERD and therefore need to be avoided. Aggravating substances include coffee, chocolate, peppermint, fried or fatty foods, carbonated beverages, and alcohol. Options 4 and 6 do not promote this effect.

Test-Taking Strategy: Focus on the **subject,** food items to avoid. Use knowledge of the effect of various foods on LES

Telegram & Insta: NCLEX_RN_Edu

pressure and GERD. However, if you are unsure, note that options 4 and 6 are the most healthful food items.
Reference(s): Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1081-1082.

8. *Answer:* 4
Rationale: The nurse places highest priority on assessing for return of the gag reflex. This assessment addresses the client's airway. The nurse also monitors the client's vital signs and for a sudden increase in temperature, which could indicate perforation of the gastrointestinal tract. This complication would be accompanied by other signs as well, such as pain. Monitoring for sore throat and heartburn are also important; however, the client's airway is the priority.
Test-Taking Strategy: Note the **strategic words,** *highest priority.* Use the **ABCs—airway, breathing, and circulation.** The correct option addresses the airway.
Reference: Urden, L., Stacy, K., & Lough, M. (2020). *Priorities in critical care nursing.* (8th ed.). St. Louis: Elsevier. p. 370.

9. *Answer:* 3
Rationale: The client does have to lie still for ERCP, which takes about 1 hour to perform. The client also has to sign a consent form. Intravenous sedation is given to relax the client, and an anesthetic spray is used to help keep the client from gagging as the endoscope is passed.
Test-Taking Strategy: Note the **strategic words,** *needs further information.* These words indicate a **negative event query** and ask you to select an option that is incorrect. Invasive procedures require consent, so option 1 can be eliminated. Noting the name of the procedure and considering the anatomical location will assist you in eliminating options 2 and 4.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 841, 843.

10. *Answer:* 2
Rationale: Hepatitis A is transmitted by the fecal-oral route via contaminated water or food (improperly cooked shellfish), or infected food handlers. Hepatitis B, C, and D are transmitted most commonly via infected blood or body fluids, such as in the cases of intravenous drug abuse, history of blood transfusion, or unprotected sex with multiple partners.
Test-Taking Strategy: Focus on the **subject,** hepatitis A. Recalling the modes of transmission of the various types of hepatitis is required to answer this question. Remember that hepatitis A is transmitted by the fecal-oral route.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 969.

11. *Answer:* 4
Rationale: Following cholecystectomy, drainage from the T-tube is initially bloody and then turns a greenish-brown color. The drainage is measured as output. The amount of expected drainage will range from 500 to 1000 mL/day. The nurse would document the output.
Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Options 1 and 2 can be eliminated because a T-tube is not irrigated and would not be clamped with this amount of drainage. From the remaining options, you must know normal expected findings following this surgical procedure.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1182.

12. *Answer:* 4
Rationale: Perforation of an ulcer is a surgical emergency and is characterized by sudden, sharp, intolerably severe pain beginning in the midepigastric area and spreading over the abdomen, which becomes rigid and boardlike. Nausea and vomiting may occur. Tachycardia may occur as hypovolemic shock develops. Numbness in the legs is not an associated finding.
Test-Taking Strategy: Focus on the **subject,** perforation. Option 2 can be eliminated easily because it is not related to perforation. Eliminate option 1 next because tachycardia rather than bradycardia would develop if perforation occurs. From the remaining options, note the **strategic words**, *most likely*, to help direct you to the correct option.
Reference: Urden, L., Stacy, K., & Lough, M. (2020). *Priorities in critical care nursing.* (8th ed.). St. Louis: Elsevier. p. 376.

13. *Answer:* 3
Rationale: In a gastrojejunostomy (Billroth II procedure), the proximal remnant of the stomach is anastomosed to the proximal jejunum. Patency of the nasogastric tube is critical for preventing the retention of gastric secretions. The nurse would never irrigate or reposition the gastric tube after gastric surgery, unless specifically prescribed by the primary health care provider. In this situation, the nurse needs to clarify the prescription. Options 1, 2, and 4 are appropriate postoperative interventions.
Test-Taking Strategy: Note the words *question and verify.* Eliminate options 1, 2, and 4 because they are **comparable or alike** and are general postoperative measures. Also, consider the anatomical location of the surgical procedure to assist in directing you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1206.

14. *Answer:* 2
Rationale: *Dumping syndrome* is a term that refers to a constellation of vasomotor symptoms that occurs after eating, especially following a gastrojejunostomy (Billroth II procedure). Early manifestations usually occur within 30 minutes of eating and include vertigo, tachycardia, syncope, sweating, pallor, palpitations, and the desire to lie down. The nurse would instruct the client to decrease the amount of fluid taken at meals. Complex carbohydrate foods such as oatmeal and other whole-grain foods high in fiber will help to prevent dumping syndrome but high sugar foods, such as candy, table sugar, syrup, sodas and juices, cakes, and pastries need to be avoided whether they are homemade or store bought. The client needs to lie down for 15 to 30 minutes after eating to delay gastric emptying; ambulation will cause rapid gastric emptying.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Eliminate options 1 and 4 first because these measures are **comparable or alike** and will promote gastric emptying. Next use knowledge about the dietary measures to prevent dumping syndrome to answer correctly. Also, note the **closed-ended word** *only* in option 3.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1106-1108.

15. *Answer:* 1, 2, 5
Rationale: The client with acute pancreatitis normally is placed on NPO status to rest the pancreas and suppress gastrointestinal secretions, so adequate intravenous hydration is necessary. Because abdominal pain is a prominent symptom of pancreatitis, pain medications such as hydromorphone are prescribed. Some clients experience lessened pain by assuming positions that flex the trunk, with the knees drawn up to the chest. A side-lying position with the head elevated 45 degrees decreases tension on the abdomen and may help ease the pain. The client is susceptible to respiratory infections because the retroperitoneal fluid raises the diaphragm, which causes the client to take shallow, guarded abdominal breaths. Therefore, measures such as turning, coughing, and deep breathing are instituted.
Test-Taking Strategy: Focus on the **subject,** care for the client with acute pancreatitis. Think about the pathophysiology associated with pancreatitis and note the word *acute*. This will assist in selecting the correct options.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 994-996.

16. *Answer:* 1
Rationale: Crohn's disease is an inflammatory disease that can occur anywhere in the gastrointestinal tract but most often affects the terminal ileum and leads to thickening and scarring, a narrowed lumen, fistulas, ulcerations, and abscesses. It is characterized by exacerbations and remissions. If stress increases the symptoms of the disease, the client is taught stress-management techniques and may require additional counseling. The client is taught to avoid gastrointestinal stimulants containing caffeine and to follow a high-calorie and high-protein diet. A low-fiber diet may be prescribed, especially during periods of exacerbation.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction.* These words indicate a **negative event query** and ask you to select an option that is incorrect. Also, focus on the **data in the question** and that the question addresses exacerbation. Knowing that the client should consume a diet high in protein and calories and low in fiber during exacerbations will direct you to option 1. Options 2, 3, and 4 are correct statements.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 942, 944.

17. *Answer:* 3
Rationale: Asterixis is irregular flapping movements of the fingers and wrists when the hands and arms are outstretched, with the palms down, wrists bent up, and fingers spread. Asterixis is the most common and reliable sign that hepatic encephalopathy is developing. Options 1, 2, and 4 are incorrect.
Test-Taking Strategy: Focus on the **subject,** the procedure for assessment of asterixis. Remember that asterixis is irregular flapping movements of the fingers and wrists. This will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1160; Urden, L., Stacy, K., & Lough, M. (2020). *Priorities in critical care nursing.* (8th ed.). St. Louis: Elsevier. p. 383.

18. *Answer:* 3
Rationale: Cirrhosis is a chronic, progressive disease of the liver characterized by diffuse degeneration and destruction of hepatocytes. The serum ammonia level assesses the ability of the liver to deaminate protein byproducts. Normal reference interval is 10 to 80 mcg/dL (6 to 47 mcmol/L). Most of the ammonia in the body is found in the gastrointestinal tract. Protein provided by the diet is transported to the liver by the portal vein. The liver breaks down protein, which results in the formation of ammonia. Foods high in protein would be avoided since the client's ammonia level is elevated above the normal range; therefore, pasta with sauce would be the best selection.
Test-Taking Strategy: Focus on the **subject,** an ammonia level of 85 mcg/dL (51 mcmol/L). Realizing that this result is above the normal range will direct you away from selecting high-protein foods, such as pork, cheese, eggs, and fish.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1162.

19. *Answer:* 3
Rationale: A frequent symptom of duodenal ulcer is pain that is relieved by food intake. These clients generally describe the pain as a burning, heavy, sharp, or "hungry" pain that often localizes in the midepigastric area. The client with duodenal ulcer usually does not experience weight loss or nausea and vomiting. These symptoms are more typical in the client with a gastric ulcer.
Test-Taking Strategy: Eliminate options 1 and 2 because they are **comparable or alike**; if the client is vomiting, weight loss will occur. Next, think about the symptoms of duodenal and gastric ulcer. Choose the correct option over option 4, knowing that the pain does not radiate down the right arm and that a pattern of pain-food-relief occurs with duodenal ulcer.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 905-906.

Telegram & Insta: NCLEX_RN_Edu

20. *Answer:* 1

Rationale: Hiatal hernia is caused by a protrusion of a portion of the stomach above the diaphragm where the esophagus usually is positioned. The client usually experiences pain from reflux caused by ingestion of irritating foods, lying flat following meals or at night, and eating large or fatty meals. Relief is obtained with the intake of small, frequent, and bland meals; use of H_2-receptor antagonists and antacids; and elevation of the thorax following meals and during sleep.

Test-Taking Strategy: Focus on the **subject,** the action contraindicated in hiatal hernia. Thinking about the pathophysiology that occurs in hiatal hernia will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 897.

21. *Answer:* 2

Rationale: Ischemia of the stoma would be associated with a dusky or bluish or purple color. A beefy red and shiny stoma is normal and expected. Skin excoriation does need to be addressed and treated, but immediate attention is required for purple discoloration of the stoma. Semiformed stool is a normal finding.

Test-Taking Strategy: Note the **strategic word,** *immediate,* and focus on the **subject,** the observation that requires primary health care provider notification. Note the words *purple discoloration* in option 2. Recall that purple indicates ischemia.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1121.

22. *Answer:* 1

Rationale: As peristalsis returns following creation of a colostomy, the client begins to pass malodorous flatus. This indicates returning bowel function and is an expected event. Within 72 hours of surgery, the client would begin passing stool via the colostomy. Options 2, 3, and 4 are incorrect interpretations.

Test-Taking Strategy: Focus on the **subject,** that the client is passing flatus from the stoma. Think about the normal functioning of the gastrointestinal tract and note the time frame in the question to assist in answering correctly.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 954.

23. *Answer:* 4

Rationale: A frequent complication that occurs following ileostomy is fluid and electrolyte imbalance. The client requires constant monitoring of intake and output to prevent this from occurring. Losses require replacement by intravenous infusion until the client can tolerate a diet orally. Intestinal obstruction is a less frequent complication. Fat malabsorption and folate deficiency are complications that could occur later in the postoperative period.

Test-Taking Strategy: Note the **strategic word,** *most.* Also note the **subject,** an ileostomy. Remember that ileostomy drainage is liquid, placing the client at risk for fluid and electrolyte imbalance.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 956.

24. *Answer:* 1

Rationale: IBS is a functional gastrointestinal disorder that causes chronic or recurrent diarrhea, constipation, and/or abdominal pain and bloating. Dietary fiber and bulk help produce bulky, soft stools and establish regular bowel elimination habits. Therefore, the client would consume a high-fiber diet. Eating regular meals, drinking 8 to 10 cups of liquid a day, and chewing food slowly help promote normal bowel function. Medication therapy depends on the main symptoms of IBS. Bulk-forming laxatives or antidiarrheal agents or other agents may be prescribed.

Test-Taking Strategy: Note the **strategic words,** *need for further teaching.* These words indicate a **negative event query** and the need to select the incorrect client statement. Think about the pathophysiology associated with IBS to answer correctly. Also, note the word *limit* in option 1. With IBS, dietary fiber and bulk are important to assist in controlling symptoms.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 942, 944.

25. *Answer:* 1

Rationale: Early manifestations of dumping syndrome occur 5 to 30 minutes after eating. Symptoms include vertigo, tachycardia, syncope, sweating, pallor, palpitations, and the desire to lie down.

Test-Taking Strategy: Note the **strategic word,** *early.* Think about the pathophysiology associated with dumping syndrome and its etiology to answer correctly.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1106-1107.

CHAPTER 50

Gastrointestinal Medications

Contributors: Lisa Nicholas, MSN, RN
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS **Inflammation; Tissue Integrity**

I. Antacids (Table 50.1; Fig. 50.1)

A. React with gastric acid to produce neutral salts or salts of low acidity

B. Inactivate pepsin and enhance mucosal protection but do not coat the ulcer crater

C. These medications are used for peptic ulcer disease and gastroesophageal reflux disease.

D. These medications should be taken on a regular schedule; some are prescribed to be taken 1 and 3 hours after each meal and at bedtime.

E. To provide maximum benefit, treatment should elevate the gastric pH above 5.

F. Antacid tablets should be chewed thoroughly and followed with a glass of water or milk.

G. Liquid preparations should be shaken before dispensing.

To prevent interactions with other medications and interference with the action of other medications, allow 1 hour between antacid administration and the administration of other medications.

II. Gastric Protectants

A. Misoprostol

1. An antisecretory medication that enhances mucosal defenses
2. Suppresses secretion of gastric acid and maintains submucosal blood flow by promoting vasodilation
3. Used to prevent gastric ulcers caused by nonsteroidal antiinflammatory drugs and aspirin
4. Administered with meals
5. Causes diarrhea and abdominal pain
6. Contraindicated for use in pregnancy

B. Sucralfate

1. Creates a protective barrier against acid and pepsin
2. Administered orally; should be taken on an empty stomach
3. May cause constipation
4. May impede absorption of warfarin sodium, phenytoin, theophylline, digoxin, and some antibiotics; should be administered at least 2 hours apart from these medications

III. Histamine (H_2)-Receptor Antagonists

A. Description

1. Suppress secretion of gastric acid
2. Alleviate symptoms of heartburn and assist in preventing complications of peptic ulcer disease
3. Prevent stress ulcers and reduce the recurrence of all ulcers
4. Promote healing in gastroesophageal reflux disease
5. Are contraindicated in hypersensitive clients
6. Used with caution in clients with impaired renal or hepatic function

B. Cimetidine

1. Can be administered orally, intramuscularly, or intravenously
2. Food reduces the rate of absorption; if taken orally with meals, absorption will be slowed.
3. Intravenous administration can cause hypotension and dysrhythmias.
4. Antacids can decrease the absorption of oral cimetidine.
5. Cimetidine and antacids should be administered at least 1 hour apart from each other.

Telegram & Insta: NCLEX_RN_Edu

TABLE 50.1 Classification of Antacids and Considerations

Classification	Considerations
Aluminum compounds	Aluminum hydroxide is used to treat hyperphosphatemia; therefore, it can cause hypophosphatemia.
	Aluminum hydroxide can reduce the effects of tetracyclines, warfarin sodium, and digoxin and can reduce phosphate absorption and thereby cause hypophosphatemia.
	Aluminum compounds contain significant amounts of sodium; they should be used with caution in clients with hypertension and heart failure.
	The most common side effect is constipation.
Magnesium compounds	Magnesium hydroxide is also a saline laxative, and the most prominent side effect is diarrhea; it is usually administered in combination with aluminum hydroxide, an antacid that assists in preventing diarrhea.
	Magnesium compounds are contraindicated in clients with intestinal obstruction, appendicitis, or undiagnosed abdominal pain.
	In clients with renal impairment, magnesium can accumulate to high levels, causing signs of toxicity.
Calcium compounds	Calcium carbonate can cause acid rebound.
	Calcium compounds are rapid acting and release carbon dioxide in the stomach, causing belching and flatulence.
	A common side effect is constipation. Milk-alkali syndrome (headache, urinary frequency, anorexia, nausea/vomiting, fatigue) can occur. (The client should avoid milk products and vitamin D supplements.)
Sodium bicarbonate	Sodium bicarbonate has a rapid onset, liberates carbon dioxide, increases intra-abdominal pressure, and promotes flatulence.
	Sodium bicarbonate should be used with caution in clients with hypertension and heart failure.
	Sodium bicarbonate can cause systemic alkalosis in clients with renal impairment.
	Sodium bicarbonate is useful for treating acidosis and elevating urinary pH to promote excretion of acidic medications following overdose.

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process*. (9th ed.). St. Louis: Elsevier. p. 786.

6. Cimetidine passes the blood–brain barrier, and central nervous system side and adverse effects can occur; it may cause mental confusion, agitation, psychosis, depression, anxiety, and disorientation.
7. Dosage should be reduced in clients with renal impairment.
8. Cimetidine inhibits hepatic drug-metabolizing enzymes and can cause many medication levels to rise; if administered with warfarin sodium, phenytoin, theophylline, or lidocaine, the dosages of these medications should be reduced.

C. Famotidine and nizatidine
1. Famotidine and nizatidine are similar to cimetidine.
2. These medications do not need to be administered with food.

IV. Proton Pump Inhibitors (Box 50.1)

A. Suppress gastric acid secretion
B. Used to treat active ulcer disease, erosive esophagitis, and pathological hypersecretory conditions
C. Contraindicated in hypersensitivity
D. Common side effects include headache, diarrhea, abdominal pain, and nausea.

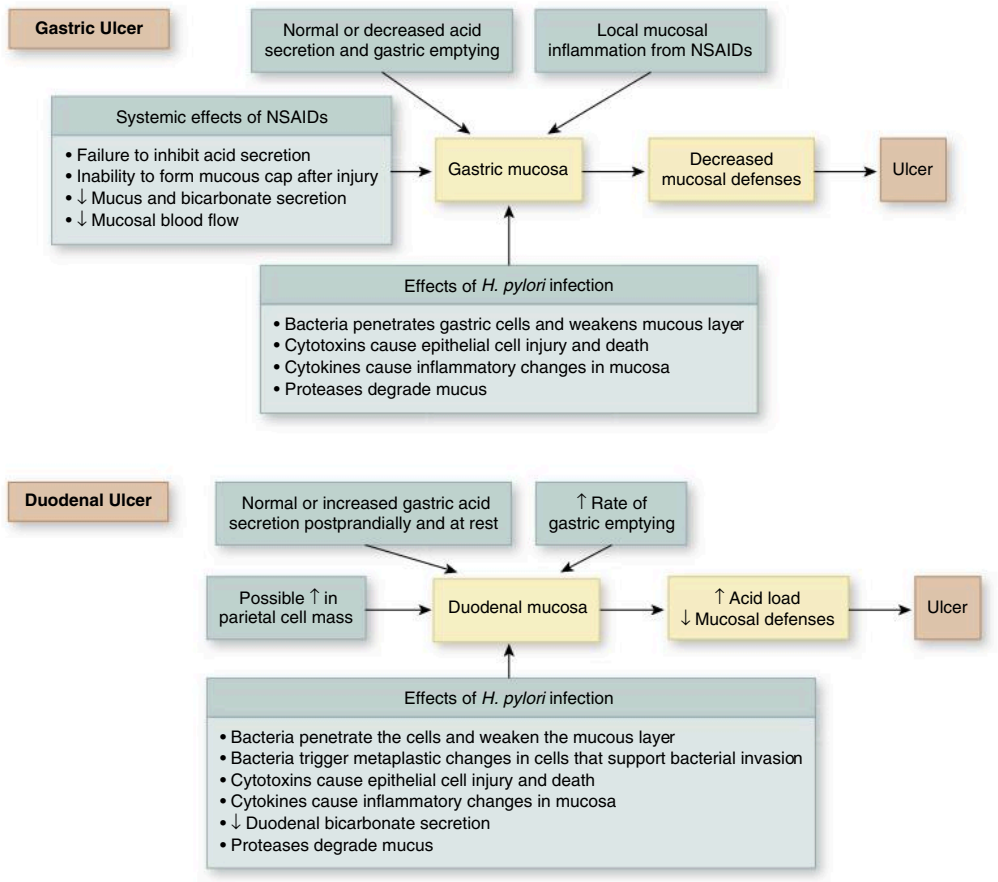
V. Medication Regimens to Treat *Helicobacter pylori* Infections (Box 50.2)

A. An antibacterial agent alone is not effective for eradicating *H. pylori*, because the bacterium readily becomes resistant to the agent.
B. Triple or quadruple therapy with a variety of medication combinations is used (if triple therapy fails, quadruple therapy is recommended).

VI. Prokinetic Agent

A. Medication: Metoclopramide
B. Stimulates motility of the upper gastrointestinal tract and increases the rate of gastric emptying without stimulating gastric, biliary, or pancreatic secretions
C. Used to treat gastroesophageal reflux and paralytic ileus; also used as an antiemetic
D. May cause restlessness, drowsiness, extrapyramidal reactions, dizziness, insomnia, and headache
E. Usually administered 30 minutes before meals and at bedtime
F. Contraindicated in clients with sensitivity and in clients with mechanical obstruction, perforation, or gastrointestinal hemorrhage

Telegram & Insta: NCLEX_RN_Edu



Gastric Ulcer
Normal or decreased acid secretion and gastric emptying
Local mucosal inflammation from NSAIDs
Systemic effects of NSAIDs
• Failure to inhibit acid secretion
• Inability to form mucous cap after injury
• ↓ Mucus and bicarbonate secretion
• ↓ Mucosal blood flow
Gastric mucosa
Decreased mucosal defenses
Ulcer
Effects of H. pylori infection
• Bacteria penetrates gastric cells and weakens mucous layer
• Cytotoxins cause epithelial cell injury and death
• Cytokines cause inflammatory changes in mucosa
• Proteases degrade mucus
Duodenal Ulcer
Normal or increased gastric acid secretion postprandially and at rest
↑ Rate of gastric emptying
Possible ↑ in parietal cell mass
Duodenal mucosa
↑ Acid load
↓ Mucosal defenses
Ulcer
Effects of H. pylori infection
• Bacteria penetrate the cells and weaken the mucous layer
• Bacteria trigger metaplastic changes in cells that support bacterial invasion
• Cytotoxins cause epithelial cell injury and death
• Cytokines cause inflammatory changes in mucosa
• ↓ Duodenal bicarbonate secretion
• Proteases degrade mucus

FIG. 50.1 Pathophysiological components of peptic ulcer. *H. pylori, Helicobacter pylori; NSAIDs,* nonsteroidal antiinflammatory drugs.

BOX 50.1 Proton Pump Inhibitors

- Dexlansoprazole
- Esomeprazole
- Lansoprazole
- Omeprazole
- Pantoprazole
- Rabeprazole

BOX 50.3 Bile Acid Sequestrants

- Cholestyramine
- Colesevelam
- Colestipol

BOX 50.2 Medication Regimens to Treat *Helicobacter pylori* Infections

Triple Therapy

- Esomeprazole, amoxicillin, clarithromycin
- Lansoprazole, amoxicillin, clarithromycin
- Esomeprazole, metronidazole, clarithromycin

Quadruple Therapies

- Esomeprazole, metronidazole, tetracycline, bismuth subsalicylate

Note: Additional medications may be prescribed for each level of therapy.

G. Can precipitate hypertensive crisis in clients with pheochromocytoma

H. Safety in pregnancy has not been established

I. Metoclopramide can cause parkinsonian reactions; if this occurs, the medication will be discontinued by the health care provider.

J. Anticholinergics, such as atropine, and opioid analgesics, such as morphine, antagonize the effects of metoclopramide.

K. Alcohol, sedatives, cyclosporine, and tranquilizers produce an additive effect.

VII. Bile Acid Sequestrants (Box 50.3)

A. Act by absorbing and combining with intestinal bile salts, which then are secreted in the feces, preventing intestinal reabsorption

B. Used to treat hypercholesterolemia in adults, biliary obstruction, and pruritus associated with biliary disease

C. With powdered forms, taste and palatability are often reasons for noncompliance and can be improved by the use of flavored products or mixing the medication with various juices.

D. Side and adverse effects include nausea, bloating, constipation, fecal impaction, and intestinal obstruction.

Telegram & Insta: NCLEX_RN_Edu

E. Stool softeners and other sources of fiber can be used to abate the gastrointestinal side effects.

⚠ Bile acid sequestrants are used cautiously in clients with suspected bowel obstruction or severe constipation because they can worsen these conditions.

VIII. Treating Hepatic Encephalopathy

A. Medication: Lactulose (see Clinical Judgment: Take Action Box)
B. Used in the prevention and treatment of portal systemic encephalopathy, including hepatic precoma and coma; also used in the treatment of chronic constipation
C. Promotes increased **peristalsis** and bowel evacuation, expelling ammonia from the colon and thus lowering the ammonia level (normal ammonia reference interval is 10 to 80 mcg/dL [6 to 47 mcmol/L])
D. Improves protein tolerance in clients with advanced hepatic **cirrhosis**
E. Administered orally in the form of a syrup or rectally

CLINICAL JUDGMENT: TAKE ACTION

The nurse is caring for a 62-year-old client with cirrhosis and encephalopathy. The physician prescribes lactulose for the client. The nurse monitors the client for an effective response to the medication, notes that the client is having diarrhea, and notes that the ammonia laboratory result reveals a value of 75 mcg/dL (45 mcmol/L). The nurse takes the following actions:

- Reports the normal ammonia level
- Documents the effectiveness of the lactulose
- Monitors the status of diarrhea
- Monitors intake and output
- Assesses the client for signs of dehydration
- Assists the client with getting to the commode or bathroom
- Assists the client with perineal care and personal hygiene care after a bowel movement

IX. Pancreatic Enzyme Replacements

A. Pancrelipase
B. Used to supplement or replace pancreatic enzymes and thus improve nutritional status and reduce the amount of fatty stools (a deficiency of pancreatic enzymes can compromise digestion, especially the digestion of fats)
C. Needs to be taken with all meals and snacks
D. Side and adverse effects include abdominal cramps or pain, nausea, vomiting, and diarrhea.
E. Products that contain calcium carbonate or magnesium hydroxide interfere with the action of these medications.

BOX 50.4 Medications to Treat Inflammatory Bowel Disease

Antimicrobials
- Ciprofloxacin
- Clarithromycin
- Metronidazole
- Rifaximin

5-Aminosalicylates
- Balsalazide
- Mesalamine
- Olsalazine
- Sulfasalazine

Corticosteroids
- Budesonide
- Hydrocortisone
- Prednisone

Immunosuppressants
- Azathioprine
- Cyclosporine
- Mercaptopurine
- Tacrolimus

Immunomodulators
- Adalimumab
- Certolizumab
- Infliximab
- Natalizumab

X. Treatment for Inflammatory Bowel Disease (Box 50.4)

A. Inflammatory bowel disease has two forms, **Crohn's disease** and **ulcerative colitis**.
B. Antimicrobials: May be prescribed to prevent or treat secondary infection (see Chapter 64 for information on antimicrobials)
C. 5-Aminosalicylates (5-ASAs): Decrease gastrointestinal inflammation; side and adverse effects include nausea, rash, arthralgia, and hematological disorders.
D. Corticosteroids: Act as an antiinflammatory to decrease gastrointestinal inflammation (see Chapter 48 for information on glucocorticoids and corticosteroids)
E. Immunomodulators: Monoclonal antibodies modulate the immune response to induce and maintain remission (see Box 50.4 for specific immunomodulators).

XI. Treatment for Irritable Bowel Syndrome (IBS)

A. Irritable bowel syndrome is a gastrointestinal disorder that is characterized by crampy abdominal pain accompanied by diarrhea, constipation, or both.
B. Pharmacological treatment depends on the main symptom, constipation or diarrhea.
C. Constipation-predominant IBS (IBS-C) treatment
   1. Bulk-forming laxatives, usually taken at mealtimes with a full glass of water
   2. Lubiprostone: Chloride channel activator that increases fluid in the intestines to promote bowel elimination; needs to be taken with food and water
   3. Linaclotide: Stimulates receptors in the intestines to promote bowel transit time; taken daily 30 minutes before breakfast
   4. See Box 50.5 for a list of additional medications to treat constipation.

Telegram & Insta: NCLEX_RN_Edu

BOX 50.5 Laxatives

Bulk-Forming
- Methylcellulose
- Polycarbophil
- Psyllium

Stimulants
- Bisacodyl
- Senna

Emollient
- Docusate sodium

Osmotics
- Magnesium hydroxide
- Magnesium citrate
- Sodium phosphates
- Polyethylene glycol and electrolytes
- Lactulose

BOX 50.6 Medications to Control Diarrhea

Opioids and Related Medications
- Diphenoxylate with atropine sulfate
- Loperamide hydrochloride

Other Antidiarrheals
- Bismuth subsalicylate
- Bulk-forming medications
- Anticholinergic antispasmodics: dicyclomine, glycopyrrolate

BOX 50.7 Commonly Administered Antiemetics

Serotonin Antagonists
- Granisetron
- Ondansetron
- Palonosetron

Glucocorticoids
- Dexamethasone
- Methylprednisolone

Substance P/Neurokinin-1 Antagonists
- Aprepitant
- Fosaprepitant
- Rolapitant

Benzodiazepine
- Lorazepam

Dopamine Antagonists

Phenothiazines
- Chlorpromazine
- Perphenazine
- Prochlorperazine
- Promethazine

Butyrophenones
- Haloperidol

Others
- Amisulpride
- Metoclopramide
- Trimethobenzamide

Cannabinoids
- Dronabinol
- Nabilone

Anticholinergics
- Scopolamine transdermal

Antihistamines
- Dimenhydrinate
- Diphenhydramine
- Hydroxyzine
- Meclizine hydrochloride

D. Diarrhea-predominant IBS (IBS-D) treatment
1. Alosetron
   - **a.** A selective serotonin receptor antagonist
   - **b.** Can cause adverse effects such as constipation, impaction, bowel obstruction, perforation of the bowel, and ischemic colitis
   - **c.** A strict risk management procedure must be followed, including monitoring for serious adverse effects, reporting them, and immediate discontinuation of the medication if they arise.
2. Antidiarrheal medications: See Box 50.6 for a list of additional medications to treat diarrhea.

XII. Antiemetics (Box 50.7)

A. Medications used to control vomiting and motion sickness

B. The choice of the antiemetic is determined by the cause of the nausea and vomiting.

C. Monitor vital signs and intake and output and for signs of dehydration and fluid and electrolyte imbalances.

D. Limit odors in the client's room when the client is nauseated or vomiting.

E. Limit oral intake to clear liquids when the client is nauseated or vomiting.

Antiemetics can cause drowsiness; therefore, a priority intervention is to protect the client from injury.

XIII. Laxatives (see Box 50.5)

A. Bulk-forming
1. Description
   - **a.** Absorb water into the feces and increase bulk to produce large and soft stools
   - **b.** Contraindicated in bowel obstruction
   - **c.** Dependency can occur with long-term use.
2. Side and adverse effects include gastrointestinal disturbances, dehydration, and electrolyte imbalances.

B. Stimulants: Stimulate motility of large intestine

C. Emollients
1. Inhibit absorption of water so fecal mass remains large and soft
2. Used to avoid straining

D. Osmotics: Attract water into the large intestine to produce bulk and stimulate peristalsis

Clients receiving a laxative need to increase fluid intake as directed by their PHCP to prevent dehydration.

XIV. Medications to Control Diarrhea (see Box 50.6)

A. Identify and treat the underlying cause, treat dehydration, replace fluids and electrolytes, relieve abdominal discomfort and cramping, and reduce the passage of stool

B. Opioids
1. Opioids are effective antidiarrheal medications that decrease intestinal motility and peristalsis.
2. When poisons, infections, or bacterial toxins are the cause of the diarrhea, opioids worsen the condition by delaying the elimination of toxins.

PRACTICE QUESTIONS

1. A client with Crohn's disease is scheduled to receive an infusion of infliximab. What intervention by the nurse will determine the **effectiveness** of treatment?
   1. Monitoring the leukocyte count for 2 days after the infusion
   2. Checking the frequency and consistency of bowel movements
   3. Checking serum liver enzyme levels before and after the infusion
   4. Carrying out a Hematest on gastric fluids after the infusion is completed

2. A client with gastroenteritis has an as-needed prescription for loperamide hydrochloride. For which condition would the nurse administer this medication?
   1. Constipation
   2. Abdominal pain
   3. An episode of diarrhea
   4. Hematest-positive nasogastric tube drainage

3. A client with gastroenteritis has an as-needed prescription for ondansetron. For which condition(s) would the nurse administer this medication?
   1. Paralytic ileus
   2. Incisional pain
   3. Urinary retention
   4. Nausea and vomiting

4. A client with chronic pancreatitis has begun medication therapy with pancrelipase. The nurse evaluates that the medication is having the optimal intended benefit if which effect is observed?
   1. Weight loss
   2. Relief of heartburn
   3. Reduction of steatorrhea
   4. Absence of abdominal pain

5. An older client with peptic ulcer disease recently has been taking cimetidine. The nurse monitors the client for which **most** frequent central nervous system side effect of this medication?
   1. Tremors
   2. Dizziness
   3. Confusion
   4. Hallucinations

6. A client with a gastric ulcer has a prescription for sucralfate 1 gram by mouth 4 times daily. The nurse would schedule the medication for which times?
   1. With meals and at bedtime
   2. Every 6 hours around the clock
   3. One hour after meals and at bedtime
   4. One hour before meals and at bedtime

7. A client with gastritis who uses nonsteroidal anti-inflammatory drugs (NSAIDs) has been taking misoprostol. The nurse determines that the misoprostol is having the intended therapeutic effect if which finding is noted?
   1. Resolved diarrhea
   2. Relief of epigastric pain
   3. Decreased platelet count
   4. Decreased white blood cell count

8. A client with peptic ulcer disease has been taking omeprazole for 4 weeks. The ambulatory care nurse evaluates that the client is receiving the optimal intended effect of the medication if the client reports the absence of which symptom?
   1. Diarrhea
   2. Heartburn
   3. Flatulence
   4. Constipation

9. A client with a peptic ulcer is diagnosed with a Helicobacter pylori infection. The nurse is teaching the client about the medications prescribed, including clarithromycin, esomeprazole, and amoxicillin. Which statement by the client indicates the **best** understanding of the medication regimen?
   1. "My ulcer will heal because these medications will kill the bacteria."
   2. "These medications are taken only when I have pain from my ulcer."
   3. "The medications will kill the bacteria and stop the acid production."
   4. "These medications will coat the ulcer and decrease the acid production in my stomach."

10. A client with gastroesophageal reflux disease has a new prescription for metoclopramide. On review of the chart, the nurse identifies that this medication can be safely administered with which condition?
    1. Intestinal obstruction
    2. Peptic ulcer with melena
    3. Diverticulitis with perforation
    4. Vomiting following cancer chemotherapy

11. The nurse determines that the client **needs further instruction** on cimetidine if which statements were made? **Select all that apply.**
    - ❑ 1. "I will take the cimetidine with my meals."
    - ❑ 2. "I'll know the medication is working if my diarrhea stops."
    - ❑ 3. "My episodes of heartburn will decrease if the medication is effective."
    - ❑ 4. "Taking the cimetidine with an antacid will increase its effectiveness."
    - ❑ 5. "I will notify my doctor if I become depressed or anxious."
    - ❑ 6. "Some of my blood levels will need to be monitored closely since I also take warfarin for atrial fibrillation."

Telegram & Insta: NCLEX_RN_Edu

12. The nurse has given instructions to a client with biliary disease who has just been prescribed cholestyramine. Which statement by the client indicates a **need for further instruction**?

1. "I will continue to take vitamin supplements."
2. "This medication will help lower my cholesterol."
3. "This medication would only be taken with water."
4. "A high-fiber diet is important while taking this medication."

ANSWERS

1. *Answer:* 2

Rationale: The principal manifestations of Crohn's disease are diarrhea and abdominal pain. Infliximab is an immunomodulator that reduces the degree of inflammation in the colon, thereby reducing the diarrhea. Options 1, 3, and 4 are unrelated to this medication.

Test-Taking Strategy: Focus on the **subject,** treatment for Crohn's disease, and note the **strategic word,** *effectiveness*. Eliminate option 4, because gastric bleeding is not a characteristic of Crohn's disease. Monitoring the leukocyte count and liver enzyme levels is appropriate when infliximab is given but not to evaluate the effectiveness of treatment, eliminating options 1 and 3.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1145-1146.

2. *Answer:* 3

Rationale: Loperamide is an antidiarrheal agent. It is used to manage acute and chronic diarrhea in conditions such as inflammatory bowel disease. Loperamide also can be used to reduce the volume of drainage from an ileostomy. It is not used for the conditions in options 1, 2, and 4.

Test-Taking Strategy: Focus on the **subject,** the action of loperamide. Recalling that this medication is an antidiarrheal agent will direct you to the correct option.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 926; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 798-799, 806.

3. *Answer:* 4

Rationale: Ondansetron is an antiemetic used to treat postoperative nausea and vomiting, as well as nausea and vomiting associated with chemotherapy. The other options are incorrect reasons for administering this medication.

Test-Taking Strategy: Focus on the **subject,** the action of ondansetron. Recalling that this medication is an antiemetic will direct you to the correct option.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 891; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 816.

4. *Answer:* 3

Rationale: Pancrelipase is a pancreatic enzyme used in clients with pancreatitis as a digestive aid. The medication would reduce the amount of fatty stools (steatorrhea). Another intended effect could be improved nutritional status. It is not used to treat abdominal pain or heartburn. Its use could result in weight gain but would not result in weight loss if it is aiding in digestion.

Test-Taking Strategy: Focus on the **subject,** intended benefit of the medication, and on the name of the medication. Use knowledge of physiology of the pancreas and the function of pancreatic enzymes to assist in directing you to the correct option.

Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 979-980.

5. *Answer:* 3

Rationale: Cimetidine is a histamine (H_2)-receptor antagonist. Older clients are especially susceptible to central nervous system side effects of cimetidine. The most frequent of these is confusion. Less common central nervous system side effects include headache, dizziness, drowsiness, and hallucinations.

Test-Taking Strategy: Note the **strategic word,** *most*. Use knowledge of the older client and medication effects to direct you to the correct option.

References: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 788; Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 278-279.

6. *Answer:* 4

Rationale: Sucralfate is a gastric protectant. The medication would be scheduled for administration 1 hour before meals and at bedtime. The medication is timed to allow it to form a protective coating over the ulcer before food intake stimulates gastric acid production and mechanical irritation. The other options are incorrect.

Test-Taking Strategy: Focus on the **subject,** times to administer sucralfate. Note the client's diagnosis and think about the pathophysiology associated with a gastric ulcer to assist in directing you to the correct option.

References: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier.

Telegram & Insta: NCLEX_RN_Edu

p. 1097; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier.

7. *Answer:* 2
Rationale: The client who uses NSAIDs is prone to gastric mucosal injury. Misoprostol is a gastric protectant and is given specifically to prevent this occurrence in clients taking NSAIDs frequently. Diarrhea can be a side effect of the medication but is not an intended effect. Options 3 and 4 are unrelated to the purpose of misoprostol.
Test-Taking Strategy: Focus on the **subject,** the intended therapeutic effect of misoprostol for a client who chronically uses NSAIDs. This indicates that the medication is being given to prevent the occurrence of specific symptoms. Recalling that NSAIDs can cause gastric mucosal injury will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 899.

8. *Answer:* 2
Rationale: Omeprazole is a proton pump inhibitor classified as an antiulcer agent. The intended effect of the medication is relief of pain from gastric irritation, often called *heartburn* by clients. Omeprazole is not used to treat the conditions identified in options 1, 3, and 4.
Test-Taking Strategy: Focus on the **subject,** the optimal intended effect of omeprazole. Recalling that this medication is a proton pump inhibitor will direct you to the correct option.
References: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 789, 793; Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 949-950.

9. *Answer:* 3
Rationale: Triple therapy for *H. pylori* infection usually includes two antibacterial medications and a proton pump inhibitor. Clarithromycin and amoxicillin are antibacterials. Esomeprazole is a proton pump inhibitor. These medications will kill the bacteria and decrease acid production.
Test-Taking Strategy: Focus on the **subject,** the medications and their actions, and note the **strategic word,** *best*. Eliminate option 1 because the medications do more than kill the bacteria. These medications are taken not only when there is pain but continually until gone, usually for 1 to 2 weeks. This will eliminate option 2. These medications do not coat the ulcer, eliminating option 4.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 907-908.

10. *Answer:* 4
Rationale: Metoclopramide is a gastrointestinal stimulant and antiemetic. Because it is a gastrointestinal stimulant, it is contraindicated with gastrointestinal obstruction, hemorrhage, or perforation. It is used in the treatment of vomiting after surgery, chemotherapy, or radiation.
Test-Taking Strategy: Focus on the **subject,** safe use of metoclopramide. Recalling the classification and action of this medication and that it is an antiemetic will direct you to the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 838-839.

11. *Answer:* 1, 2, 4
Rationale: Cimetidine, a histamine (H_2)-receptor antagonist, helps alleviate the symptom of heartburn, not diarrhea. Because cimetidine crosses the blood–brain barrier, central nervous system side and adverse effects, such as mental confusion, agitation, depression, and anxiety, can occur. Food reduces the rate of absorption, so if cimetidine is taken with meals, absorption will be slowed. Antacids decrease the absorption of cimetidine and need to be taken at least 1 hour apart. If cimetidine is concomitantly administered with warfarin therapy, warfarin doses may need to be reduced, so prothrombin and international normalized ratio results must be followed.
Test-Taking Strategy: Note the **strategic words,** *needs further instruction*. These words indicate a **negative event query** and ask you to select the options that are incorrect statements. Think about the therapeutic effect, adverse effects, and potential medication interactions to direct you to the correct options.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 278-279.

12. *Answer:* 3
Rationale: Cholestyramine is a bile acid sequestrant used to lower the cholesterol level, and treat biliary obstruction and pruritus associated with biliary disease. Client adherence to the medication regimen is a problem because of its taste and palatability. The use of flavored products or fruit juices can improve the taste. Some side effects of bile acid sequestrants include constipation and decreased vitamin absorption.
Test-Taking Strategy: Note the **strategic words,** *need for further instruction*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Note the **closed-ended word** *only* in the correct option.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. p. 584.

UNIT XI

Respiratory Problems of the Adult Client

Pyramid to Success

The Pyramid to Success focuses on infectious diseases and respiratory care in relation to respiratory problems. Pyramid Points focus on the client with pneumonia, respiratory failure, chronic obstructive pulmonary disease, pneumothorax, influenza, tuberculosis, and COVID-19. Treatment of respiratory problems including medications and other therapies, adequate nutrition and rest to promote the healing process, and prevention of transmission and progression of the disease are discussed. Focus on assisting the client to cope with the social isolation issues that exist during the period of illness and on teaching the client and family the critical measures of screening, preventing respiratory disease, and the prevention and transmission of infectious airborne and droplet diseases.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Collaborating with the interprofessional team in the management of the respiratory problem
Discussing consultations and referrals related to the respiratory problem
Ensuring necessary isolation precautions are in effect and maintained
Ensuring that informed consent related to invasive procedures has been obtained
Handling infectious materials such as sputum or body fluids safely
Maintaining confidentiality
Maintaining respiratory precautions, standard precautions, and other precautions
Prioritizing hypotheses based on client needs

Health Promotion and Maintenance

Educating the client about adequate fluid and nutritional intake
Educating the client about breathing exercises and respiratory therapy and care
Educating the client about medication administration
Educating the client about the need for follow-up care
Educating the client about the prevention of transmission of infection
Informing the client about health promotion programs
Performing respiratory assessment techniques
Preventing respiratory problems and infectious diseases
Providing health screening related to risks for respiratory problems
Recognizing cues that indicate risk factors for a respiratory problem or infectious disease

Psychosocial Integrity

Considering religious, cultural, and spiritual influences when providing care
Discussing body image changes related to respiratory problems
Discussing end-of-life and grief and loss issues
Discussing situational role changes
Identifying coping strategies
Identifying support systems and community resources
Promoting support and comfort during times when social isolation is required

Physiological Integrity

Administering medications
Evaluating the effectiveness of prescribed treatments
Managing respiratory illnesses and infectious diseases
Monitoring for acid-base imbalances
Monitoring for alterations in body systems
Monitoring for infectious diseases
Providing nutrition and oral hygiene
Taking action in emergency situations

Telegram & Insta: NCLEX_RN_Edu

CHAPTER 51

Respiratory Problems

Contributor: Jessica Grimm, DNP, APRN, ACNP-BC, CNE

PRIORITY CONCEPTS Gas Exchange; Perfusion

I. Anatomy and Physiology

A. Primary functions of the respiratory system
- **1.** Provides oxygen for metabolism in the tissues
- **2.** Removes carbon dioxide, the waste product of metabolism

B. Secondary functions of the respiratory system
- **1.** Facilitates sense of smell
- **2.** Produces speech
- **3.** Maintains acid–base balance
- **4.** Maintains body water levels
- **5.** Maintains heat balance

C. Upper respiratory airway
- **1.** Nose: Humidifies, warms, and filters inspired air
- **2.** Sinuses: Air-filled cavities within the hollow bones that surround the nasal passages and provide resonance during speech
- **3.** Pharynx
  - **a.** Passageway for the respiratory and digestive tracts located behind the oral and nasal cavities
  - **b.** Divided into the nasopharynx, oropharynx, and laryngopharynx
- **4.** Larynx
  - **a.** Located just below the pharynx at the root of the tongue; commonly called the *voice box*
  - **b.** Contains two pairs of vocal cords, the false and true cords
  - **c.** The opening between the true vocal cords is the glottis. The glottis plays an important role in coughing, which is the most fundamental defense mechanism of the lungs.
- **5.** Epiglottis
  - **a.** Leaf-shaped elastic flap structure at the top of the larynx
  - **b.** Prevents food from entering the tracheobronchial tree by closing over the glottis during swallowing

D. Lower respiratory airway
- **1.** Trachea: Located in front of the esophagus; branches into the right and left mainstem bronchi at the carina
- **2.** Mainstem bronchi
  - **a.** Begin at the carina
  - **b.** The right bronchus is slightly wider, shorter, and more vertical than the left bronchus.
  - **c.** Divide into secondary or lobar bronchi that enter each of the five lobes of the lung
  - **d.** The bronchi are lined with cilia, which propel mucus up and away from the lower airway to the trachea, where it can be expectorated or swallowed.
- **3.** Bronchioles
  - **a.** Branch from the secondary bronchi and subdivide into the small terminal and respiratory bronchioles
  - **b.** Contain no cartilage and depend on the elastic recoil of the lung for patency
  - **c.** The terminal bronchioles contain no cilia and do not participate in gas exchange.
- **4.** Alveolar ducts and alveoli
  - **a.** *Acinus* (plural, *acini*) is a term used to indicate all structures distal to the terminal bronchiole.
  - **b.** Branch from the respiratory bronchioles
  - **c.** Alveolar sacs, which arise from the ducts, contain clusters of alveoli, which are the basic units of gas exchange.
  - **d.** Type 2 alveolar cells in the walls of the alveoli secrete surfactant, a phospholipid protein that reduces the surface tension in the alveoli; without surfactant, the alveoli would collapse.
- **5.** Lungs
  - **a.** Located in the pleural cavity in the thorax
  - **b.** Extend from just above the clavicles to the diaphragm, the major muscle of inspiration

Telegram & Insta: NCLEX_RN_Edu

c. The right lung, which is larger than the left, is divided into three lobes: the upper, middle, and lower lobes.
d. The left lung, which is narrower than the right lung to accommodate the heart, is divided into two lobes.
e. The respiratory structures are innervated by the phrenic nerve, the vagus nerve, and the thoracic nerves.
f. The parietal pleura lines the inside of the thoracic cavity, including the upper surface of the diaphragm.
g. The visceral pleura covers the pulmonary surfaces.
h. A thin fluid layer, which is produced by the cells lining the pleura, lubricates the visceral pleura and the parietal pleura, allowing them to glide smoothly and painlessly during respiration.
i. Blood flows throughout the lungs via the pulmonary circulation system.

6. Accessory muscles of respiration include the scalene muscles, which elevate the first two ribs; the sternocleidomastoid muscles, which raise the sternum; and the trapezius and pectoralis muscles, which fix the shoulders.

7. The respiratory process
a. The diaphragm descends into the abdominal cavity during inspiration, causing negative pressure in the lungs.
b. The negative pressure draws air from the area of greater pressure, the atmosphere, into the area of lesser pressure, the lungs.
c. In the lungs, air passes through the terminal bronchioles into the alveoli and diffuses into surrounding capillaries, then travels to the rest of the body to oxygenate the body tissues.
d. At the end of inspiration, the diaphragm and intercostal muscles relax and the lungs recoil.
e. As the lungs recoil, pressure within the lungs becomes higher than atmospheric pressure, causing the air, which now contains the cellular waste products carbon dioxide and water, to move from the alveoli in the lungs to the atmosphere.
f. Effective gas exchange depends on distribution of gas (ventilation) and blood (perfusion) in all portions of the lungs.

II. Diagnostic Tests

A. Risk factors for respiratory disorders (Box 51.1)

B. Chest x-ray film (radiograph)
1. Description: Provides information regarding the anatomical location and appearance of the lungs
2. Preprocedure
a. Remove all jewelry and other metal objects from the chest area.

BOX 51.1 Risk Factors for Respiratory Disorders

- Chest injury
- Crowded living conditions
- Environmental allergies
- Exposure to chemicals and environmental pollutants
- Family history of infectious disease
- Frequent respiratory illnesses
- Geographical residence and travel to foreign countries
- Smoking
- Surgery
- Use of chewing tobacco
- Viral syndromes

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Saunders.

b. Assess the client's ability to inhale and hold their breath.
3. Postprocedure: No special care is required after the procedure unless there are abnormal findings.

⚠ Question the client regarding pregnancy or the possibility of pregnancy before performing radiography studies.

C. Sputum specimen
1. Description: Specimen obtained by expectoration or tracheal suctioning to assist in the identification of organisms or abnormal cells (see Box 70.11 in Chapter 70)
2. Sputum for culture and sensitivity should be collected before antimicrobial therapy is initiated unless the test is being performed to evaluate the effectiveness of medications already being given.
3. Preprocedure
a. Determine the specific purpose of collection, and check institutional policy for the appropriate method for collection.
b. Obtain an early morning sterile specimen by suctioning or expectoration after a respiratory treatment if a treatment is prescribed; give the client the specimen cup the night before.
c. Instruct the client to rinse the mouth with water before collection to decrease contamination of the sputum sample from particles in the oropharynx.
d. Obtain 15 mL of sputum.
e. Instruct the client to take several deep breaths and then cough deeply to obtain sputum. Remind the client that sputum comes from the lungs and that saliva is not sputum.
f. Collect the specimen before the client begins antibiotic therapy. If already started on antibiotic therapy, ensure that the laboratory can utilize an antimicrobial removal device when analyzing the specimen.

Telegram & Insta: NCLEX_RN_Edu

4. Postprocedure
   a. If a culture of sputum is prescribed, transport the labeled specimen to the laboratory immediately; indicate whether the client was currently on antimicrobial therapy at the time of collection.
   b. Assist the client with mouth care.

⚠ Ensure that an informed consent was obtained for any invasive procedure. Vital signs are measured before the procedure and monitored postprocedure to detect signs of complications.

D. Laryngoscopy and bronchoscopy
1. Description: Direct visual examination of the larynx, trachea, and bronchi with a fiberoptic bronchoscope
2. Preprocedure
   a. Maintain NPO (nothing by mouth) status as prescribed.
   b. Assess the results of coagulation studies.
   c. Remove dentures and eyeglasses.
   d. Instruct the client to perform good mouth care to prevent bacteria from entering into the lungs from the oropharynx.
   e. Establish an intravenous (IV) access as necessary, and administer medication for sedation as prescribed. A local anesthetic spray may be used; instruct the client not to swallow the spray and to expectorate any excess into a basin.
   f. Have emergency resuscitation supplies readily available.
3. Postprocedure
   a. Maintain the client in a semi-Fowler's position.
   b. Assess for the return of the gag reflex.
   c. Maintain NPO status until the gag reflex returns.
   d. Monitor for bloody sputum.
   e. Monitor respiratory status, particularly if sedation has been administered.
   f. Monitor for complications, such as bronchospasm or bronchial perforation, indicated by facial or neck crepitus, dysrhythmias, hemorrhage, hypoxemia, and pneumothorax.
   g. Notify the primary health care provider (PHCP) if signs of complications occur.
   h. Inform the client that warm saline gargles and lozenges may be helpful for a sore throat.
   i. Biopsy or culture results are available in 2 to 7 days.

E. Endobronchial ultrasound (EBUS)
1. Tissue samples are obtained from central lung masses and lymph nodes, using a bronchoscope with the help of ultrasound guidance.
2. Tissue samples are used for diagnosing and staging lung cancer, detecting infections, and identifying inflammatory diseases that affect the lungs, such as sarcoidosis.
3. Postprocedure, the client is monitored for signs of bleeding and respiratory distress.

F. Pulmonary angiography
1. Description
   a. A fluoroscopic procedure in which a catheter is inserted through the antecubital or femoral vein into the pulmonary artery or one of its branches
   b. Involves an injection of iodine or radiopaque contrast material
2. Preprocedure
   a. Assess for allergies to iodine, seafood, or other radiopaque dyes.
   b. Maintain NPO status as prescribed.
   c. Assess results of coagulation studies.
   d. Establish an IV access.
   e. Administer sedation as prescribed.
   f. Instruct the client to lie still during the procedure.
   g. Instruct the client that they may feel an urge to cough, flushing, nausea, or a salty taste following injection of the dye.
   h. Have emergency resuscitation equipment available.
3. Postprocedure
   a. Avoid taking blood pressures for 24 hours in the extremity used for the injection.
   b. Monitor peripheral neurovascular status of the affected extremity.
   c. Assess insertion site for bleeding.
   d. Monitor for reaction to the dye.
   e. Apply cold compresses to the puncture site to reduce swelling or discomfort.

G. Thoracentesis
1. Description: Removal of fluid or air from the pleural space via transthoracic aspiration
2. Preprocedure
   a. Prepare the client for ultrasound or chest radiograph, if prescribed, before the procedure.
   b. Assess results of coagulation studies.
   c. Note that the client is positioned sitting upright, with the arms and shoulders supported by a table at the bedside during the procedure (Fig. 51.1).
   d. If the client cannot sit up, the client is placed lying in bed toward the unaffected side, with the head of the bed elevated.
   e. Instruct the client not to cough, breathe deeply, or move during the procedure.
   f. Administer cough suppressant as prescribed before the procedure if the client has a troublesome cough.

Telegram & Insta: NCLEX_RN_Edu

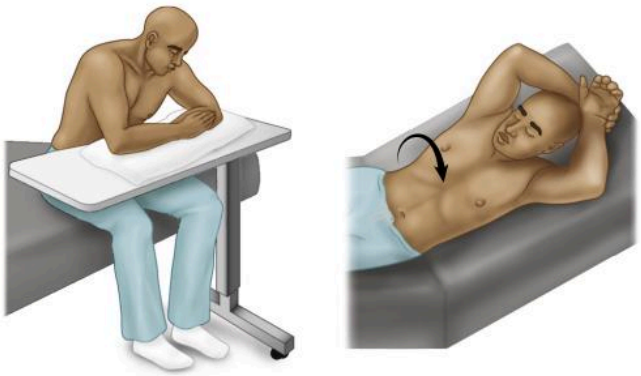

FIG. 51.1 Positions for thoracentesis.

3. Postprocedure
   a. Monitor respiratory status.
   b. Apply a pressure dressing, and assess the puncture site for bleeding and crepitus.
   c. Monitor for signs of pneumothorax, air embolism, and pulmonary edema.
   d. Review chest x-ray results to monitor for pneumothorax.

H. Pulmonary function tests
1. Description: Tests used to evaluate lung mechanics, gas exchange, and acid–base disturbance through spirometric measurements, lung volumes, and arterial blood gas levels
2. Preprocedure
   a. Determine whether an analgesic that may depress the respiratory function is being administered.
   b. Consult with the PHCP regarding withholding bronchodilators before testing, or alternatively whether the testing will be done prior to and after administration of a bronchodilator.
   c. Instruct the client to void before the procedure and to wear loose clothing.
   d. Remove dentures.
   e. Instruct the client to refrain from smoking or eating a heavy meal for 4 to 6 hours before the test.
   f. Measure height and weight to determine predictive values.
3. Postprocedure: The client may resume a normal diet and any bronchodilators and respiratory treatments that were withheld before the procedure.

Clients with severe respiratory problems are occasionally exhausted after the testing and will need rest.

I. Lung biopsy
1. Description
   a. A transbronchial biopsy and a transbronchial needle aspiration may be performed to obtain tissue for analysis by culture or cytological examination.
   b. An open lung biopsy is performed in the operating room.
2. Preprocedure
   a. Maintain NPO status as prescribed.
   b. Inform the client that a local anesthetic will be used for a needle biopsy but that a sensation of pressure during needle insertion and aspiration may be felt.
   c. Administer analgesics and sedatives as prescribed.
   d. Instruct client to remain still during the procedure.
3. Postprocedure
   a. Apply a dressing to the biopsy site and monitor for drainage or bleeding.
   b. Monitor for signs of respiratory distress, and notify the PHCP if they occur.
   c. Monitor for signs of pneumothorax and air emboli, and notify the PHCP if they occur.
   d. Prepare the client for chest radiography if prescribed.

J. Spiral (helical) computed tomography (CT) scan
1. Frequently used test to diagnose pulmonary embolism
2. IV injection of contrast medium is used; if the client cannot have contrast medium, a ventilation-perfusion (V/Q) scan will be done.
3. The scanner rotates around the body, allowing for a three-dimensional picture of all regions of the lungs.

K. V/Q lung scan
1. Description
   a. The perfusion scan evaluates blood flow to the lungs.
   b. The ventilation scan determines the patency of the pulmonary airways and detects abnormalities in ventilation.
   c. A radionuclide may be injected for the procedure.
   d. Generally this is the preferred test to use with renal impairment.
   e. Encourage the client to drink fluids to avoid renal impairment.
2. Preprocedure
   a. Assess the client for allergies to dye, iodine, or seafood.
   b. Remove jewelry around the chest area.
   c. Review breathing methods that may be required during testing.
   d. Establish an IV access.
   e. Administer sedation if prescribed.
   f. Have emergency resuscitation equipment available.
3. Postprocedure
   a. Monitor the client for reaction to the radionuclide.

Telegram & Insta: NCLEX_RN_Edu

b. Instruct the client that the radionuclide clears from the body in about 8 hours.
c. Encourage increased fluid intake to clear the dye from the body if there is no fluid restriction.

L. Computed tomography pulmonary angiography
1. Description
a. The scan visualizes the pulmonary arteries and blood flow.
b. Its main use is to diagnose pulmonary embolism and is the preferred method.
c. A contrast dye is injected.
2. Preprocedure: Similar to the V/Q lung scan; in addition, renal function should be adequate, and dosing of the contrast should be done by a pharmacist.
3. Postprocedure: Similar to the V/Q lung scan

M. Skin tests: A skin test uses an intradermal injection to help diagnose various infectious diseases (Box 51.2).

N. Arterial blood gases (ABGs)
1. Description: Measurement of the dissolved oxygen and carbon dioxide in the arterial blood helps indicate the acid–base state and how well oxygen is being carried to the body.
2. Preprocedure and postprocedure care, normal results, and analysis of results: See Chapter 9.

⚠ Avoid suctioning the client before drawing an ABG sample, because the suctioning procedure will deplete the client's oxygen, resulting in inaccurate ABG results.

O. Pulse oximetry: See Chapter 10.

P. D-dimer
1. A blood test that measures clot formation and lysis that results from the degradation of fibrin
2. Helps diagnose (a positive test result) the presence of thrombus in conditions such as deep vein thrombosis, pulmonary embolism, or stroke; it is also used to diagnose disseminated intravascular coagulation (DIC) and to monitor the effectiveness of treatment.
3. D-dimer has high sensitivity, low specificity for diagnosing clot formation.
4. The normal D-dimer level is less than 50 ng/mL (less than 3.0 mmol/L); normal fibrinogen is 60 to 100 mg/dL (2.0 to 5.0 g/L).

III. Respiratory Treatments (see Chapter 70)

IV. Chest Injuries

A. Rib fracture
1. Description
a. Results from direct blunt chest trauma and causes a potential for intrathoracic injury, such as pneumothorax, hemothorax, or pulmonary contusion

BOX 51.2 Tuberculin Skin Test Procedure

1. Determine hypersensitivity or previous reactions to skin tests.
2. Assess whether the client has received Bacille-Calmette-Guerin (BCG) in the past, which would demonstrate a positive reaction.
3. Use a skin site that is free of excessive body hair, dermatitis, and blemishes.
4. Apply the injection at the upper third of the inner surface of the left arm.
5. Circle and mark the injection test site with indelible ink.
6. Document the date, time, and test site.
7. Advise the client not to scratch the test site to prevent infection and possible abscess formation.
8. Instruct the client to avoid washing the test site.
9. Assess the reaction at the injection site 48 to 72 hours after administration of the test antigen.
10. Assess the test site for the amount of induration (hard swelling) in millimeters and for the presence of erythema and vesiculation (small blister-like elevations).

b. Pain with movement, deep breathing, and coughing results in impaired ventilation and inadequate clearance of secretions.
c. Can be serious and life-threatening when three or more ribs are fractured, with preexisting disease (particularly cardiopulmonary disease), or for the elderly client
2. Assessment
a. Pain and tenderness at the injury site that increases with inspiration
b. Shallow respirations
c. Client splints chest using a pillow as needed; external splints are not recommended because they limit chest wall expansion.
d. Fractures noted on rib series x-ray
3. Interventions
a. Note that the ribs usually reunite spontaneously.
b. Client has a higher risk of developing pneumonia after rib fractures.
c. Open reduction and internal fixation of the ribs (rib plating) may be done.
d. Place the client in a Fowler's position.
e. Administer pain medication as prescribed to maintain adequate ventilatory status.
f. Monitor for increased respiratory distress.
g. Instruct the client to self-splint with the hands, arms, or a pillow.
h. Prepare the client for an intercostal nerve block as prescribed if the pain is severe.

B. Flail chest
1. Description
a. Occurs from blunt chest trauma associated with accidents, which may result in hemothorax and rib fractures

Telegram & Insta: NCLEX_RN_Edu

b. The loose segment of the chest wall becomes paradoxical to the expansion and contraction of the rest of the chest wall.

2. Assessment
- **a.** Paradoxical respirations (inward movement of a segment of the thorax during inspiration with outward movement during expiration)
- **b.** Severe pain in the chest
- **c.** Dyspnea
- **d.** Cyanosis
- **e.** Tachycardia
- **f.** Hypotension
- **g.** Tachypnea, shallow respirations
- **h.** Diminished breath sounds

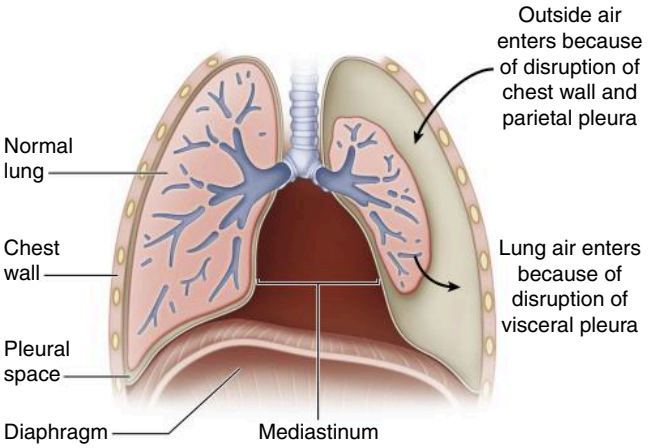
3. Interventions
- **a.** Maintain the client in a Fowler's position if cervical spine injury has been ruled out.
- **b.** Administer oxygen as prescribed.
- **c.** Monitor for increased respiratory distress.
- **d.** Encourage coughing and deep breathing.
- **e.** Administer pain medication as prescribed.
- **f.** Maintain bed rest and limit activity to reduce oxygen demands.
- **g.** Open reduction and internal fixation of the ribs (rib plating) may be done.
- **h.** Prepare for intubation with mechanical ventilation, with positive end-expiratory pressure (PEEP) for severe flail chest associated with respiratory failure and shock (see Chapter 70).

C. Pulmonary contusion

1. Description
- **a.** Characterized by interstitial hemorrhage associated with intra-alveolar hemorrhage, resulting in decreased pulmonary compliance
- **b.** The major complication is acute respiratory distress syndrome.

2. Assessment
- **a.** Dyspnea
- **b.** Restlessness
- **c.** Increased bronchial secretions
- **d.** Hypoxemia
- **e.** Hemoptysis
- **f.** Decreased breath sounds
- **g.** Crackles and wheezes

3. Interventions
- **a.** Maintain a patent airway and adequate ventilation.
- **b.** Place the client in a Fowler's position.
- **c.** Administer oxygen as prescribed.
- **d.** Monitor for increased respiratory distress.
- **e.** Maintain bed rest and limit activity to reduce oxygen demands.
- **f.** Provide oxygen and give fluids as prescribed.
- **g.** Prepare for mechanical ventilation with PEEP if required.



Outside air enters because of disruption of chest wall and parietal pleura
Normal lung
Chest wall
Lung air enters because of disruption of visceral pleura
Pleural space
Diaphragm
Mediastinum

FIG. 51.2 Pneumothorax. Air in the pleural space causes the lungs to collapse around the hilus and may push the mediastinal contents (heart and great vessels) toward the other lung.

D. Pneumothorax (Fig. 51.2)

1. Description
- **a.** Accumulation of atmospheric air in the pleural space, which results in a rise in intrathoracic pressure and reduced vital capacity, or the greatest amount of air expired from the lungs after taking a deep breath
- **b.** The loss of negative intrapleural pressure results in collapse of the lung.
- **c.** A spontaneous pneumothorax occurs with the rupture of a pulmonary bleb, or small air-containing spaces deep in the lung.
- **d.** An open pneumothorax occurs when an opening through the chest wall allows the entrance of positive atmospheric air pressure into the pleural space.
- **e.** A tension pneumothorax occurs from a blunt chest injury or from mechanical ventilation with PEEP when a buildup of positive pressure occurs in the pleural space.

2. Assessment (Box 51.3)

3. Interventions
- **a.** Diagnosis of pneumothorax is made by chest x-ray, which will show air or fluid in the pleural space and reduction of lung volume.
- **b.** Apply a nonporous dressing over an open chest wound.
- **c.** Administer oxygen as prescribed.
- **d.** Place the client in a Fowler's position for chest trauma.
- **e.** Prepare for chest tube placement, which will remain in place until the lung has expanded fully.
- **f.** Monitor the chest tube drainage system.
- **g.** Monitor for subcutaneous emphysema.
- **h.** Review serial chest x-ray results to determine effectiveness of treatment.
- **i.** See Chapter 70 for information on caring for a client with chest tubes.

Telegram & Insta: NCLEX_RN_Edu

BOX 51.3 Assessment Findings: Pneumothorax

- Absent or markedly decreased breath sounds on affected side
- Cyanosis
- Decreased chest expansion unilaterally
- Distended neck veins
- Dyspnea
- Hypotension
- Sharp chest pain
- Subcutaneous emphysema as evidenced by crepitus on palpation
- Sucking sound with open chest wound
- Tachycardia
- Tachypnea
- Tracheal deviation to the unaffected side with tension pneumothorax

Clients with a respiratory disorder should be positioned with the head of the bed elevated.

V. Asthma (Fig. 51.3)

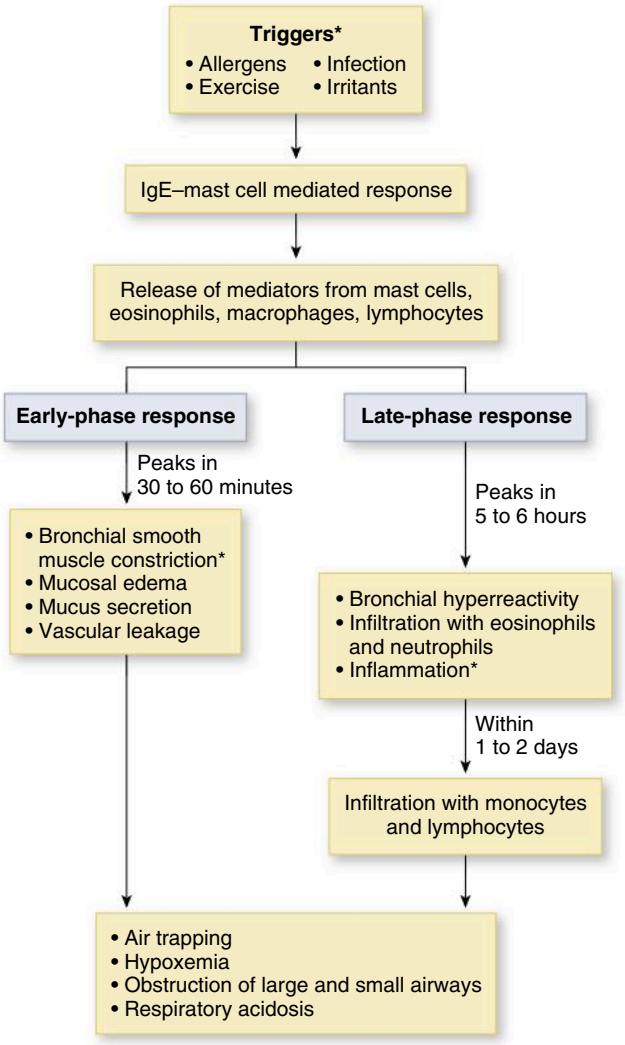
A. Description

1. Chronic inflammatory disorder of the airways that causes varying degrees of obstruction in the airways
2. Marked by airway inflammation and hyperresponsiveness to a variety of stimuli or triggers (Box 51.4).
3. Causes recurrent episodes of wheezing, breathlessness, chest tightness, and coughing associated with airflow obstruction that may resolve spontaneously; it is often reversible with treatment.
4. Severity is classified based on the clinical features before treatment.
5. Status asthmaticus is a severe life-threatening asthma episode that is refractory to treatment and may result in pneumothorax, acute cor pulmonale, or respiratory arrest.
6. Refer to Chapter 36 for additional information on asthma.

Silent breath sounds are associated with acute asthma exacerbation, may indicate impending respiratory failure due to diffuse bronchospasm, and represent a life-threatening condition.

B. Assessment

1. Restlessness
2. Wheezing or crackles
3. Absent or diminished lung sounds
4. Hyperresonance
5. Use of accessory muscles for breathing
6. Tachypnea with hyperventilation
7. Prolonged exhalation
8. Tachycardia
9. Pulsus paradoxus
10. Diaphoresis
11. Cyanosis
12. Decreased oxygen saturation
13. Pulmonary function test results that demonstrate decreased airflow rates



Triggers*
• Allergens • Infection
• Exercise • Irritants
IgE–mast cell mediated response
Release of mediators from mast cells, eosinophils, macrophages, lymphocytes
Early-phase response
Late-phase response
Peaks in 30 to 60 minutes
Peaks in 5 to 6 hours
• Bronchial smooth muscle constriction*
• Mucosal edema
• Mucus secretion
• Vascular leakage
• Bronchial hyperreactivity
• Infiltration with eosinophils and neutrophils
• Inflammation*
Within 1 to 2 days
Infiltration with monocytes and lymphocytes
• Air trapping
• Hypoxemia
• Obstruction of large and small airways
• Respiratory acidosis

FIG. 51.3 Pathophysiology in asthma. Stems with asterisks are primary processes. *IgE*, Immunoglobulin E.

C. Interventions

1. Monitor vital signs.
2. Monitor pulse oximetry.
3. Monitor peak flow.
4. Administer bronchodilators and corticosteroids as prescribed.
5. Educate the client and family on reducing stress and anxiety and avoiding environmental triggers.
6. During an acute asthma episode, provide interventions to assist with breathing (Box 51.5).

D. Client education

1. Discuss the intermittent nature of symptoms and the need for long-term management.

Telegram & Insta: NCLEX_RN_Edu

BOX 51.4 Asthma Triggers

Environmental Factors
- Animal dander
- Cockroaches
- Cold, dry air
- Dust mites
- Exhaust fumes
- Fireplaces
- Molds
- Perfumes or other products with aerosol sprays
- Pollen
- Smoke, including cigarette or cigar smoke
- Sudden weather changes

Physiological Factors
- Exercise
- Gastroesophageal reflux disease (GERD)
- Hormonal changes
- Sinusitis
- Stress
- Viral upper respiratory infection

Medications
- Acetylsalicylic acid (aspirin)
- β-Adrenergic blockers
- Nonsteroidal antiinflammatory drugs

Occupational Exposure Factors
- Agriculture
- Industrial chemicals and plastics
- Metal salts
- Pharmaceutical drugs
- Wood and vegetable dusts

Food Additives
- Beer, wine, dried fruit, shrimp, processed potatoes
- Monosodium glutamate
- Sulfites (bisulfites and metabisulfites)
- Tartrazine

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Mosby. pp. 542-543.

BOX 51.5 Nursing Interventions During an Acute Asthma Episode
- Position the client in a high-Fowler's position or sitting to aid in breathing.
- Administer oxygen as prescribed.
- Stay with the client to decrease anxiety.
- Administer bronchodilators and other nebulizer treatments as prescribed.
- Record the color, amount, and consistency of sputum, if any.
- Administer corticosteroids as prescribed.
- Administer magnesium sulfate as prescribed.
- Administer intravenous fluids as prescribed.
- Auscultate lung sounds before, during, and after treatments.

2. Identify possible triggers and measures to prevent episodes.
3. Use pursed-lip breathing before, during, and after activities that are possible triggers.
4. Management of medication and proper administration
5. Correct use of a peak flowmeter and aerochamber or "spacer" use with inhaler
6. Wear a MedicAlert bracelet.
7. Develop an asthma action plan with the PHCP and what to do if an asthma episode occurs.

VI. Chronic Obstructive Pulmonary Disease

A. Description
1. Also known as chronic obstructive lung disease and chronic airflow limitation
2. **Chronic obstructive pulmonary disease** is a disease state characterized by airflow obstruction.
3. Chronic bronchitis and **emphysema** are progressive lung diseases that fall under the general category of chronic obstructive pulmonary disease.
4. Chronic bronchitis is a condition in which the bronchial tubes become inflamed and excessive mucus production occurs as a result of irritants or injury.
5. Emphysema is a condition in which the air sacs in the lungs are damaged and enlarged, resulting in hyperinflation and breathlessness.
6. Progressive airflow limitation occurs, associated with an abnormal inflammatory response of the lungs that is not completely reversible.
7. Chronic obstructive pulmonary disease (COPD) leads to pulmonary insufficiency, pulmonary hypertension, and cor pulmonale.

B. Assessment
1. Cough
2. Exertional dyspnea
3. Wheezing and crackles
4. Sputum production
5. Weight loss
6. Barrel chest (emphysema) (Fig. 51.4)
7. Use of accessory muscles for breathing
8. Prolonged expiration
9. Orthopnea
10. Cyanosis
11. Delayed capillary refill
12. Finger clubbing
13. Cardiac dysrhythmias
14. Congestion and hyperinflation seen on chest x-ray (Fig. 51.5)
15. ABG levels that indicate respiratory acidosis with or without compensation and hypoxemia. Uncompensated respiratory acidosis in a COPD patient generally indicates an acute exacerbation of COPD.

Telegram & Insta: NCLEX_RN_Edu

16. Pulmonary function tests that demonstrate decreased vital capacity

C. Interventions

1. Monitor vital signs.
2. Administer a concentration of oxygen based on ABG values and oxygen saturation by pulse oximetry as prescribed.
3. Monitor pulse oximetry.
4. Provide respiratory treatments and chest physiotherapy (CPT).
5. Instruct the client in diaphragmatic or abdominal breathing techniques, tripod positioning, and pursed-lip breathing techniques, which increase airway pressure and keep air passages open, promoting maximal carbon dioxide expiration.
6. Record the color, amount, and consistency of sputum.
7. Suction the client's lungs, if necessary, to clear the airway and prevent infection.
8. Monitor weight.
9. Encourage small, frequent meals to maintain nutrition and prevent dyspnea.
10. Provide a high-calorie, high-protein diet with supplements.
11. Encourage fluid intake up to 3000 mL/day to keep secretions thin, unless contraindicated.
12. Place the client in a Fowler's position and leaning forward to aid in breathing (Fig. 51.6).
13. Allow activity as tolerated; include exercise conditioning and pulmonary rehabilitation to prevent muscle deconditioning; assess physical limitations and develop an activity plan based on limitations.
14. Administer bronchodilators and other nebulizer treatments as prescribed, and instruct the client in the use of oral and inhalant medications.
15. Administer corticosteroids as prescribed for exacerbations.
16. Administer mucolytics as prescribed to thin secretions.
17. Administer antibiotics for infection if prescribed.

D. Client education (Box 51.6)

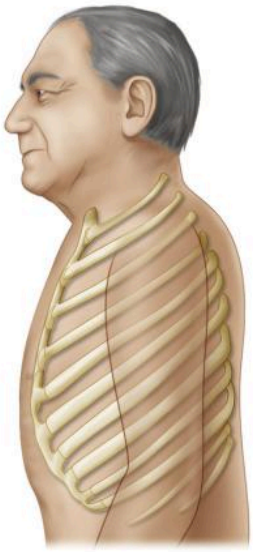


FIG. 51.4 Typical barrel chest in a client with chronic obstructive pulmonary disease.

VII. Pneumonia

A. Description

1. Infection of the pulmonary tissue, including the interstitial spaces, the alveoli, and the bronchioles
2. The edema associated with inflammation stiffens the lung, decreases lung compliance and vital capacity, and causes hypoxemia.
3. Pneumonia can be community-acquired or hospital-acquired.
4. The chest x-ray film shows lobar or segmental consolidation, or pulmonary infiltrates.

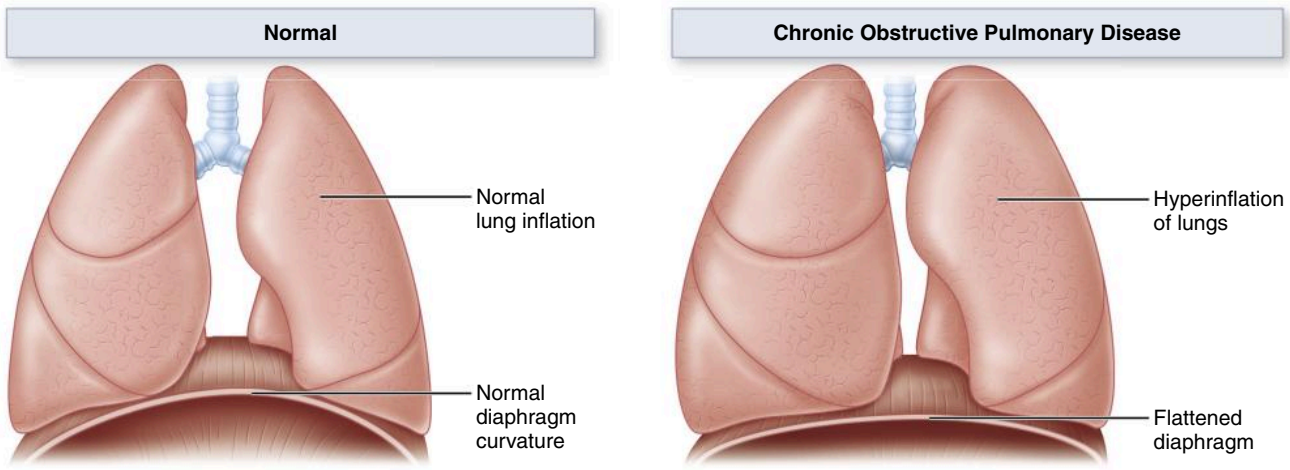

FIG. 51.5 Diaphragm shape and lung inflation in the normal client and in the client with chronic obstructive pulmonary disease.

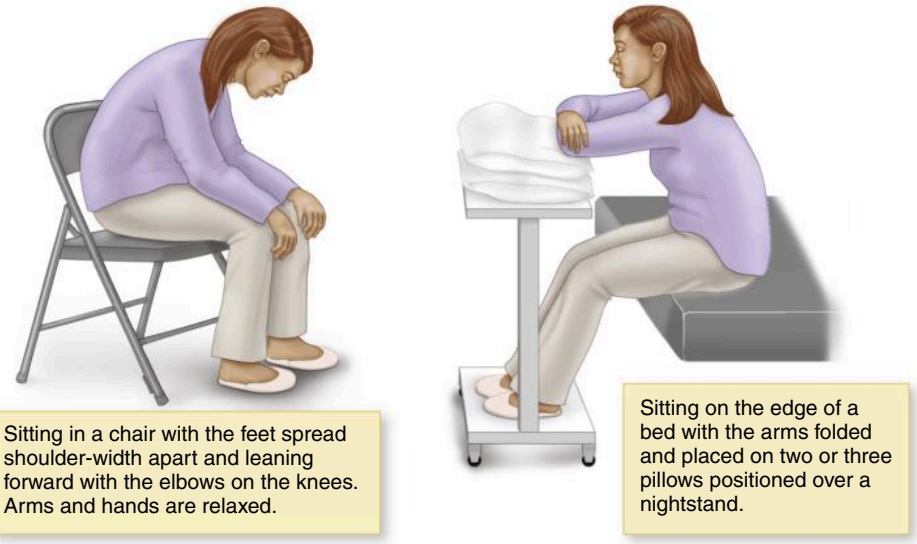
Telegram & Insta: NCLEX_RN_Edu



Sitting in a chair with the feet spread shoulder-width apart and leaning forward with the elbows on the knees. Arms and hands are relaxed.
Sitting on the edge of a bed with the arms folded and placed on two or three pillows positioned over a nightstand.

FIG. 51.6 Orthopnea positions that clients with chronic obstructive pulmonary disease can assume to ease the work of breathing.

BOX 51.6 Client Education: Chronic Obstructive Pulmonary Disease

- Adhere to activity limitations, alternating rest periods with activity.
- Avoid eating gas-producing foods, spicy foods, and extremely hot or cold foods.
- Avoid exposure to individuals with infections, and avoid crowds.
- Avoid extremes in temperature.
- Avoid fireplaces, pets, feather pillows, and other environmental allergens.
- Avoid powerful odors.
- Meet nutritional requirements.
- Receive immunizations as recommended.
- Recognize the signs and symptoms of respiratory infection and hypoxia.
- Stop smoking.
- Use medications and inhalers and/or nebulizers as prescribed.
- Use oxygen therapy as prescribed.
- Use pursed-lip and diaphragmatic or abdominal breathing.
- When dusting, use a wet cloth.

5. A sputum culture identifies the organism.
6. The white blood cell count, procalcitonin, and the erythrocyte sedimentation rate are elevated.

B. Assessment

1. Chills
2. Elevated temperature, other vital sign abnormalities
3. Pleuritic pain
4. Myalgia
5. Tachypnea, tachycardia
6. Rhonchi and wheezes
7. Use of accessory muscles for breathing, dyspnea
8. Cyanosis, especially around the mouth or conjunctiva
9. Mental status changes
10. Sputum production, hemoptysis

C. Interventions

1. Administer oxygen as prescribed.
2. Monitor respiratory status.
3. Monitor for labored respirations, cyanosis, and cold and clammy skin.
4. Encourage coughing and deep breathing and use of the incentive spirometer.
5. Place the client in a semi-Fowler's position to facilitate breathing and lung expansion.
6. Change the client's position frequently and ambulate as tolerated to mobilize secretions.
7. Provide CPT (see Chapter 70).
8. Perform nasotracheal suctioning if the client is unable to clear secretions.
9. Monitor pulse oximetry.
10. Monitor and record color, consistency, and amount of sputum.
11. Provide a high-calorie, high-protein diet with small frequent meals.
12. Monitor intake and output.
13. Encourage fluids, up to 3 L/day, to thin secretions unless contraindicated.
14. Provide a balance of rest and activity, increasing activity gradually.
15. Administer antibiotics as prescribed.
16. Administer antipyretics, bronchodilators, cough suppressants, mucolytic agents, and expectorants as prescribed.
17. Prevent the spread of infection by handwashing and the proper disposal of secretions.

D. Client education

1. About the importance of rest, proper nutrition, and adequate fluid intake

Telegram & Insta: NCLEX_RN_Edu

2. To avoid chilling and exposure to individuals with respiratory infections or viruses
3. To avoid smoke exposure
4. Regarding medications and the use of inhalants as prescribed
5. To notify the PHCP if chills, fever, dyspnea, hemoptysis, or increased fatigue occurs
6. To receive a pneumococcal vaccine as recommended by the PHCP; refer to Chapter 19 and the following website for information about this vaccine: http://www.cdc.gov/vaccines/vpd-vac/pneumo/default.htm

Teach clients that using proper handwashing techniques, disposing of respiratory secretions properly, and receiving vaccines will assist in preventing the spread of infection.

VIII. Severe Acute Respiratory Syndrome (SARS)

A. Respiratory illness caused by the coronavirus called *SARS-associated coronavirus*
B. The syndrome begins with a fever, an overall feeling of discomfort, body aches, and mild respiratory symptoms.
C. After 2 to 7 days, the client may develop a dry cough and dyspnea.
D. Infection is spread by close person-to-person contact or by direct contact with infectious material (respiratory secretions from infected persons or contact with objects contaminated with infectious droplets).
E. Prevention includes avoiding contact with those suspected of having SARS, avoiding travel to countries where an outbreak of SARS exists, avoiding close contact with crowds in areas where SARS exists, and frequent handwashing if in an area where SARS exists.

IX. COVID-19 (Coronavirus)

A. Description
   1. SARS-CoV-2 is the coronavirus that causes COVID-19.
   2. Older adults and people who have severe underlying medical conditions such as heart or lung disease or diabetes are at higher risk for developing more serious complications from COVID-19 illness.
B. Symptoms
   1. People with COVID-19 have had a wide range of symptoms reported, ranging from mild symptoms to severe illness. Symptoms may appear 2 to 14 days after exposure to the virus. Symptoms can include the following:
      a. Fever or chills
      b. Cough
      c. Shortness of breath or difficulty breathing
      d. Fatigue
      e. Muscle or body aches
      f. Headache
      g. New loss of taste or smell
      h. Sore throat
      i. Congestion or runny nose
      j. Nausea or vomiting
      k. Diarrhea
   2. Emergency care should be sought if the person is having difficulty breathing, experiences persistent pain or pressure in the chest, if the person experiences new confusion, is unable to stay awake, or if cyanosis develops.
C. Transmission and prevention
   1. COVID-19 may be spread by people who are not showing symptoms.
   2. Transmission is from person to person and via contact with the virus via respiratory droplets produced when an infected person coughs, sneezes, or talks.
   3. These droplets can land in the mouths or noses of people who are nearby or possibly be inhaled into the lungs.
   4. Droplet precautions and possibly contact precautions are necessary.
   5. Prevention includes avoiding crowds; maintaining 6 feet of social distancing, especially from sick people; handwashing; the use of hand sanitizer; wearing masks; coughing and sneezing into the elbow; keeping the hands away from the face; and keeping frequently touched surfaces cleaned and sanitized daily.
   6. Prophylactic treatment may be recommended for those exposed to coronavirus and may include selected vitamins and minerals, antiviral medication, and immune system booster supplements; the person should not begin any prophylactic treatment unless recommended by the primary health care provider.
   7. All eligible individuals are highly encouraged to receive the coronavirus vaccine and recommended boosters to protect self and others from contracting the virus.
D. Treatment
   1. Varies depending on the clinical presentation
   2. The person needs to report symptoms immediately if coronavirus is suspected and seek treatment from the primary health care provider.
   3. The primary health care provider will prescribe treatment based on the most current CDC guidelines for treating coronavirus.
   4. For additional information, refer to the Centers for Disease Control and Prevention: Coronavirus 2019 (COVID-19): https://www.cdc.gov/coronavirus/2019-ncov/faq.html

X. Influenza

A. Description
1. Also known as the flu; highly contagious acute viral respiratory infection
2. May be caused by several viruses, usually known as types A, B, and C
3. Yearly vaccination is recommended to prevent the disease, especially for those older than 50 years of age, individuals with chronic illness or who are immunocompromised, those living in institutions, and health care personnel providing direct care to clients (the vaccination is contraindicated in the individual with egg allergies).
4. Additional prevention measures include avoiding those who have developed influenza, frequent and proper handwashing, and cleaning and disinfecting surfaces that have become contaminated with secretions.
5. Avian influenza A (H5N1)
   a. Affects birds; does not usually affect humans; however, human cases have been reported in some countries.
   b. An H5N1 vaccine has been developed for use if a pandemic virus were to emerge.
   c. Reported symptoms are similar to those associated with influenza types A, B, and C.
   d. Prevention measures include thorough cooking of poultry products, avoiding contact with wild animals, frequent and proper handwashing, and cleaning and disinfecting surfaces that have become contaminated with secretions.
6. Swine (H1N1) influenza
   a. A strain of flu that consists of genetic materials from swine, avian, and human influenza viruses
   b. Signs and symptoms are similar to those that present with seasonal flu; in addition, vomiting and diarrhea commonly occur.
   c. Prevention measures and treatment are the same as for the seasonal flu.

B. Refer to Chapter 19 for information on vaccines.

C. Assessment
1. Acute onset of fever, chills, and muscle aches
2. Headache
3. Fatigue, weakness, anorexia
4. Sore throat, cough, and rhinorrhea

D. Interventions
1. Encourage rest.
2. Encourage fluids to prevent pulmonary complications (unless contraindicated).
3. Monitor lung sounds.
4. Provide supportive therapy such as antipyretics or antitussives as indicated.
5. Administer antiviral medications as prescribed for the current strain of influenza (see Chapter 52).

E. Client education
1. Thoroughly wash hands especially after blowing nose, sneezing, coughing, rubbing eyes, or touching face.
2. Avoid crowded places; stay home if not feeling well.
3. Cover mouth with tissue when sneezing or coughing.
4. Cough or sneeze in the upper sleeve rather than in the hand.

XI. Legionnaire's Disease

A. Description
1. Acute bacterial infection caused by *Legionella pneumophila*
2. Sources of the organism include contaminated cooling tower water and warm stagnant water supplies, including water vaporizers, water sonicators, whirlpool spas, and showers.
3. Person-to-person contact does not occur; the risk for infection is increased by the presence of other conditions.

B. Assessment: Influenza-like symptoms with a high fever, chills, muscle aches, and headache that may progress to dry cough, pleurisy, and sometimes diarrhea

C. Interventions: Treatment is supportive, and antibiotics may be prescribed.

XII. Pleural Effusion

A. Description
1. Pleural effusion is the collection of fluid in the pleural space.
2. Any condition that interferes with secretion or drainage of this fluid will lead to pleural effusion.

B. Assessment
1. Pleuritic pain that is sharp and increases with inspiration
2. Progressive dyspnea with decreased movement of the chest wall on the affected side
3. Dry, nonproductive cough caused by bronchial irritation
4. Tachycardia
5. Elevated temperature
6. Decreased breath sounds and/or pleural friction rub over affected area/side
7. Chest x-ray film or CT scan that shows pleural effusion and a mediastinal shift away from the fluid if the effusion is more than 250 mL

C. Interventions
1. Identify and treat the underlying cause.
2. Monitor breath sounds.
3. Place the client in a Fowler's position.
4. Encourage coughing and deep breathing.
5. Prepare the client for thoracentesis.
6. If pleural effusion is recurrent, prepare the client for pleurectomy or pleurodesis as prescribed.

Telegram & Insta: NCLEX_RN_Edu

D. Pleurectomy
1. Consists of surgically stripping the parietal pleura away from the visceral pleura
2. This produces an intense inflammatory reaction that promotes adhesion formation between the two layers during healing.

E. Pleurodesis
1. Involves the instillation of a sclerosing substance into the pleural space via a thoracotomy tube
2. The substance creates an inflammatory response that scleroses tissue together.

XIII. Empyema

A. Description
1. Collection of pus within the pleural cavity
2. The fluid is thick, opaque, and foul-smelling.
3. The most common cause is pulmonary infection and lung abscess caused by thoracic surgery or chest trauma, in which bacteria are introduced directly into the pleural space.
4. Treatment focuses on treating the infection, emptying the empyema cavity, reexpanding the lung, and controlling the infection.

B. Assessment
1. Recent febrile illness or trauma
2. Chest pain
3. Cough
4. Dyspnea
5. Anorexia and weight loss
6. Malaise
7. Elevated temperature and chills
8. Night sweats
9. Pleural exudate on chest x-ray

C. Interventions
1. Monitor breath sounds.
2. Place the client in a semi-Fowler's or high-Fowler's position.
3. Encourage coughing and deep breathing.
4. Administer antibiotics as prescribed.
5. Instruct the client to splint the chest as necessary.
6. Assist with thoracentesis or chest tube insertion to promote drainage and lung expansion.
7. If marked pleural thickening occurs, prepare the client for decortication, if prescribed; this surgical procedure involves removal of the restrictive mass of fibrin and inflammatory cells.

XIV. Pleurisy

A. Description
1. Inflammation of the visceral and parietal membranes; may be caused by pulmonary infarction or pneumonia
2. The visceral and parietal membranes rub together during respiration and cause pain.
3. Pleurisy usually occurs on one side of the chest, usually in the lower lateral portions in the chest wall.

B. Assessment
1. Knifelike pain aggravated on deep breathing and dry cough
2. Dyspnea
3. Pleural friction rub heard on auscultation

C. Interventions
1. Identify and treat the cause.
2. Monitor lung sounds.
3. Administer analgesics as prescribed.
4. Apply hot or cold applications as prescribed.
5. Encourage coughing and deep breathing.
6. Instruct the client to lie on the affected side to splint the chest.

XV. Pulmonary Embolism

A. Description
1. Occurs when a thrombus forms (most commonly in a deep vein), detaches, travels to the right side of the heart, and then lodges in a branch of the pulmonary artery
2. May be classified as massive, submassive, or low-risk pulmonary embolism
3. Clients prone to pulmonary embolism are those at risk for deep vein thrombosis, including those with prolonged immobilization, surgery, obesity, pregnancy, heart failure, advanced age, a history of thromboembolism, or a client who takes an estrogen-containing therapy.
4. Fat emboli can occur as a complication following fracture of a long bone and can cause pulmonary emboli.
5. Treatment is aimed at prevention through risk factor recognition and elimination.

B. Assessment (Box 51.7)

C. Interventions (see Clinical Judgment: Take Action Box)

BOX 51.7 Assessment Findings: Pulmonary Embolism

- Apprehension and restlessness
- Blood-tinged sputum, hemoptysis
- Chest pain
- Cough
- Crackles and wheezes on auscultation
- Cyanosis
- Diaphoresis
- Distended neck veins
- Dyspnea accompanied by anginal and pleuritic pain, exacerbated by inspiration
- Feeling of impending doom
- Hypotension
- Petechiae over the chest and axilla
- Shallow respirations, increased respiratory rate
- Tachypnea and tachycardia

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: TAKE ACTION

The nurse is caring for a client 2 days postoperative. The client has a history of deep vein thrombosis and heart failure. The client also has difficulty with mobility and is obese. The client calls the nurse and reports sudden chest pain, a cough, and difficulty breathing. The client is anxious and restless. Respirations are 26 breaths per minute and shallow. Pulse is 120 beats per minute. Blood pressure is 90/66 mm Hg. Pulse oximetry reading is 89%. Crackles are heard on auscultation of the lungs. The nurse suspects the development of pulmonary embolism and takes the following actions:

- Reassures the client and elevates the head of the bed
- Notifies the Rapid Response Team and the PHCP
- Administers oxygen
- Prepares to obtain an arterial blood gas
- Prepares for laboratory studies to be drawn and diagnostic scanning
- Prepares for the administration of heparin therapy or other therapies
- Monitors vital signs and checks lung sounds
- Provides comfort and emotional support
- Documents the event, interventions taken, and the client's response to treatment

XVI. Lung Cancer and Laryngeal Cancer: See Chapter 45 for more information.

XVII. Carbon Monoxide Poisoning: See Chapter 43 for more information.

XVIII. Histoplasmosis

A. Description
1. Pulmonary fungal infection caused by spores of *Histoplasma capsulatum*
2. Transmission occurs by the inhalation of spores, which commonly are found in contaminated soil.
3. Spores also are usually found in bird droppings.

B. Assessment
1. Similar to pneumonia
2. Positive skin test for histoplasmosis
3. Positive agglutination test
4. Splenomegaly, hepatomegaly

C. Interventions
1. Administer oxygen as prescribed.
2. Monitor breath sounds.
3. Administer antiemetics, antihistamines, antipyretics, and corticosteroids as prescribed.
4. Administer fungicidal medications as prescribed.
5. Encourage coughing and deep breathing.
6. Place the client in a semi-Fowler's position.
7. Monitor vital signs.
8. Monitor for nephrotoxicity from fungicidal medications.
9. Instruct the client to wear a mask and spray the floor with water before sweeping a barn or chicken coop.

XIX. Sarcoidosis

A. Description
1. Presence of epithelioid cell tubercles in the lung
2. The cause is unknown, but a high titer of Epstein-Barr virus may be noted.

B. Assessment
1. Night sweats
2. Chest pain
3. Fever
4. Weight loss
5. Cough and dyspnea
6. Skin nodules
7. Polyarthritis
8. Kveim test: Sarcoid node antigen is injected intradermally and causes a local nodular lesion in about 1 month.

C. Interventions
1. Administer corticosteroids to control symptoms.
2. Monitor temperature.
3. Increase fluid intake.
4. Provide frequent periods of rest.
5. Encourage small, frequent, nutritious meals.

XX. Occupational Lung Disease

A. Description
1. Caused by exposure to environmental or occupational fumes, dust, vapors, gases, bacterial or fungal antigens, and allergens; can result in acute reversible effects or chronic lung disease
2. Common disease classifications include occupational asthma pneumoconiosis (silicosis or coal miner's [black lung] disease), diffuse interstitial fibrosis (asbestosis, talcosis, berylliosis), or extrinsic allergic alveolitis (farmer's lung, bird fancier's lung, or machine operator's lung).

B. Assessment: Manifestations depend on the type of disease and respiratory symptoms.

C. Interventions
1. Prevention through the use of respiratory protective devices
2. Treatment is based on the symptoms experienced by the client.

XXI. Tuberculosis

A. Description
1. Highly communicable disease caused by *Mycobacterium tuberculosis*
2. *M. tuberculosis* is a nonmotile, nonsporulating, acid-fast rod that secretes niacin; when the bacillus reaches a susceptible site, it multiplies freely.

Telegram & Insta: NCLEX_RN_Edu

3. Because *M. tuberculosis* is an aerobic bacterium, it primarily affects the pulmonary system, especially the upper lobes, where the oxygen content is highest, but it also can affect other areas of the body, such as the brain, intestines, peritoneum, kidney, joints, and liver.
4. An exudative response causes a nonspecific pneumonitis and the development of granulomas in the lung tissue.
5. Tuberculosis has an insidious onset, and many clients are not aware of symptoms until the disease is well advanced.
6. Improper or noncompliant use of treatment programs may cause the development of mutations in the tubercle bacilli, resulting in a **multidrug-resistant** strain of **tuberculosis** (MDR-TB).
7. The goal of treatment is to prevent transmission, control symptoms, and prevent progression of the disease.

B. Risk factors (Box 51.8)

C. Transmission

1. Via the airborne route by droplet infection
2. When an infected individual coughs, laughs, sneezes, or sings, droplet nuclei containing tuberculosis bacteria enter the air and may be inhaled by others.
3. Identification of those in close contact with the infected individual is important so that they can be tested and treated as necessary.
4. When contacts have been identified, these persons are assessed with a **tuberculin skin test** and chest x-rays to determine infection with tuberculosis.
5. After the infected individual has received tuberculosis medication for 2 to 3 weeks, the risk of transmission is reduced greatly.

D. Disease progression

1. Droplets enter the lungs, and the bacteria form a tubercle lesion.
2. The defense systems of the body encapsulate the tubercle, leaving a scar.
3. If encapsulation does not occur, bacteria may enter the lymph system, travel to the lymph nodes, and cause an inflammatory response termed *granulomatous inflammation.*
4. Primary lesions form; the primary lesions may become dormant but can be reactivated and become a secondary infection when reexposed to the bacterium.
5. In an active phase, tuberculosis can cause necrosis and cavitation in the lesions, leading to rupture, the spread of necrotic tissue, and damage to various parts of the body.

E. Client history

1. Past exposure to tuberculosis
2. Client's country of origin and travel to foreign countries in which the incidence of tuberculosis is high
3. Recent history of influenza, pneumonia, febrile illness, cough, or foul-smelling sputum production
4. Previous tests for tuberculosis; results of the testing
5. Recent **bacillus Calmette-Guérin (BCG) vaccine** (a vaccine containing attenuated tubercle bacilli that may be given to persons in foreign countries or to persons traveling to foreign countries to produce increased resistance to tuberculosis)

BOX 51.8 Risk Factors for Tuberculosis

- Child younger than 5 years of age
- Drinking unpasteurized milk if the cow is infected with bovine tuberculosis
- Homeless individuals or those from a lower socioeconomic group, minority group, or refugee group
- Individuals in constant, frequent contact with an untreated or undiagnosed individual
- Individuals living in crowded areas, such as long-term care facilities, prisons, and mental health facilities
- Older client
- Individuals with malnutrition, infection, immune dysfunction, or human immunodeficiency virus infection; or immunosuppressed as a result of medication therapy
- Individuals who abuse alcohol or are intravenous drug users
- History of past exposure, travel to other countries

An individual who has received a BCG vaccine will have a positive tuberculin skin test result and should be evaluated for tuberculosis with a chest x-ray.

F. Clinical manifestations

1. May be asymptomatic in primary infection
2. Fatigue
3. Lethargy
4. Anorexia
5. Weight loss
6. Low-grade fever
7. Chills
8. Night sweats
9. Persistent cough lasting up to 3 weeks and the production of mucoid and mucopurulent sputum, which is occasionally streaked with blood
10. Chest tightness and a dull, aching chest pain may accompany the cough.

G. Chest assessment

1. A physical examination of the chest does not provide conclusive evidence of tuberculosis.
2. A chest x-ray is not definitive, but the presence of multinodular infiltrates with calcification in the upper lobes suggests tuberculosis.
3. If the disease is active, caseation and inflammation may be seen on the chest x-ray.
4. Advanced disease

Telegram & Insta: NCLEX_RN_Edu

TABLE 51.1 Classification of the Tuberculin Skin Test Reaction

Induration ≥5 mm Considered Positive in:	Induration ≥10 mm Considered Positive in:	Induration ≥15 mm Considered Positive in:
HIV-infected persons	Recent immigrants from high-prevalence countries	Any person, including persons with no known risk factors for TB
Recent contact of a person with TB disease	Injection drug users	
Persons with fibrotic changes on chest x-ray consistent with prior TB	Residents and employees in high-risk congregate settings	
Clients with organ transplants	Mycobacteriology laboratory personnel	
Persons immunosuppressed for other reasons	Persons with clinical conditions that place them at high risk	
	Children <4 years of age	
	Infants, children, and adolescents exposed to adults in high-risk categories	

HIV, Human immunodeficiency virus; *TB*, tuberculosis.
From Centers for Disease Control and Prevention: *Tuberculosis (TB) fact sheets* (website): https://www.cdc.gov/tb/publications/factsheets/testing/skintesting.htm

   a. Dullness with **percussion** over involved parenchymal areas, bronchial breath sounds, rhonchi, and crackles indicate advanced disease.
   b. Partial obstruction of a bronchus caused by endobronchial disease or compression by lymph nodes may produce localized **wheezing** and dyspnea.

H. QuantiFERON-TB Gold test
   1. A blood analysis test by an enzyme-linked immunosorbent assay
   2. A sensitive and rapid test (results can be available in 24 hours) that assists in diagnosing the client

I. Sputum cultures
   1. Sputum specimens are obtained for an acid-fast smear.
   2. A sputum culture identifying *M. tuberculosis* confirms the diagnosis.
   3. May take up to 6 weeks to become positive.
   4. After medications are started, sputum samples are obtained again to determine the effectiveness of therapy.
   5. Most clients have negative cultures after 3 months of treatment.

J. **Tuberculin skin test (TST)** (Table 51.1)
   1. A positive reaction does not mean that active disease is present but indicates previous exposure to tuberculosis or the presence of inactive (dormant) disease.
   2. Once the test result is positive, it will be positive in any future tests.
   3. Skin test interpretation depends on two factors: measurement in millimeters of the induration and the person's risk of being infected with tuberculosis and progression to disease if infected.
   4. Once an individual's skin test is positive, a chest x-ray is necessary to rule out active tuberculosis or to detect old healed lesions.

K. The hospitalized client
   1. The client with active tuberculosis is placed under airborne isolation precautions in a negative-pressure room; to maintain negative pressure, the door of the room must be tightly closed.
   2. The room should have at least six exchanges of fresh air per hour and should be ventilated to the outside environment, if possible.
   3. The nurse wears a particulate respirator (a special individually fitted mask) when caring for the client and a gown when the possibility of clothing contamination exists.
   4. Thorough handwashing is required before and after caring for the client.
   5. If the client needs to leave the room for a test or procedure, the client is required to wear a surgical mask.
   6. Respiratory isolation is discontinued when the client is no longer considered infectious. An N95 mask should be worn when entering the room until isolation is discontinued.
   7. After the infected individual has received tuberculosis medication for 2 to 3 weeks, the risk of transmission is reduced greatly.

L. Client education (Box 51.9)

Telegram & Insta: NCLEX_RN_Edu

BOX 51.9 Client Education: Tuberculosis

- Provide the client and family with information about tuberculosis and allay concerns about the contagious aspect of the infection.
- Instruct the client to follow the medication regimen exactly as prescribed and always to have a supply of the medication on hand.
- Advise the client that the medication regimen is continued up to 12 months, depending on the situation.
- Advise the client of the side and adverse effects of the medication and ways of minimizing them to ensure compliance.
- Reassure the client that after 2 to 3 weeks of medication therapy, it is unlikely that the client will infect anyone.
- Advise the client to resume activities gradually.
- Instruct the client about the need for adequate nutrition and a well-balanced diet (foods rich in iron, protein, and vitamin C) to promote healing and to prevent recurrence of the infection.
- Inform the client and family that respiratory isolation is not necessary because family members already have been exposed.
- Instruct the client to cover the mouth and nose when coughing or sneezing and to put used tissues into plastic bags.
- Instruct the client and family about thorough handwashing.
- Inform the client that a sputum culture is needed every 2 to 4 weeks once medication therapy is initiated.
- Inform the client that when the results of three sputum cultures are negative, the client is no longer considered infectious and usually can return to former employment.
- Advise the client to avoid excessive exposure to silicone or dust because these substances can cause further lung damage.
- Instruct the client regarding the importance of compliance with treatment, follow-up care, and sputum cultures, as prescribed.
- Notify the public health department.

PRACTICE QUESTIONS

1. The emergency department nurse is assessing a client who has sustained a blunt injury to the chest wall. Which finding indicates the presence of a pneumothorax in this client?
1. A low respiratory rate
2. Diminished breath sounds
3. The presence of a barrel chest
4. A sucking sound at the site of injury

2. The nurse is caring for a client hospitalized with acute exacerbation of chronic obstructive pulmonary disease. Which findings would the nurse expect to note on assessment of this client? **Select all that apply.**
- ❑ 1. A low arterial P_{CO_2} level
- ❑ 2. A hyperinflated chest noted on the chest x-ray
- ❑ 3. Decreased oxygen saturation with mild exercise
- ❑ 4. A widened diaphragm noted on the chest x-ray
- ❑ 5. Pulmonary function tests that demonstrate increased vital capacity

3. The nurse is preparing a list of home care instructions for a client who has been hospitalized and treated for tuberculosis. Which instructions would the nurse include on the list? **Select all that apply.**
- ❑ 1. Activities should be resumed gradually.
- ❑ 2. Avoid contact with other individuals, except family members, for at least 6 months.
- ❑ 3. A sputum culture is needed every 2 to 4 weeks once medication therapy is initiated.
- ❑ 4. Respiratory isolation is not necessary, because family members already have been exposed.
- ❑ 5. Cover the mouth and nose when coughing or sneezing and put used tissues in plastic bags.
- ❑ 6. When one sputum culture is negative, the client is no longer considered infectious and usually can return to former employment.

4. The nurse is caring for a client after a bronchoscopy and biopsy. Which finding, if noted in the client, would the nurse **immediately** report to the primary health care provider?
1. Dry cough
2. Hematuria
3. Bronchospasm
4. Blood-streaked sputum

5. The nurse is assessing the respiratory status of a client who has suffered a fractured rib. The nurse would expect to note which finding?
1. Slow, deep respirations
2. Rapid, deep respirations
3. Paradoxical respirations
4. Pain, especially with inspiration

6. A client with a chest injury has suffered flail chest. The nurse assesses the client for which **most** distinctive sign of flail chest?
1. Cyanosis
2. Hypotension
3. Paradoxical chest movement
4. Dyspnea, especially on exhalation

7. The nurse is assessing a client with multiple trauma who is at risk for developing acute respiratory distress syndrome. The nurse would assess for which **earliest** sign of acute respiratory distress syndrome?
1. Bilateral wheezing
2. Inspiratory crackles
3. Intercostal retractions
4. Increased respiratory rate

Telegram & Insta: NCLEX_RN_Edu

8. The nurse has conducted discharge teaching with a client diagnosed with tuberculosis who has been receiving medication for 2 weeks. The nurse determines that the client has understood the information if the client makes which statement?
1. "I need to continue medication therapy for 1 month."
2. "I can't shop at the mall for the next 6 months."
3. "I can return to work if a sputum culture comes back negative."
4. "I won't be contagious after 2 to 3 weeks of medication therapy."

9. The nurse is preparing to give a bed bath to an immobilized client with tuberculosis. The nurse would wear which items when performing this care?
1. Surgical mask and gloves
2. Particulate respirator, gown, and gloves
3. Particulate respirator and protective eyewear
4. Surgical mask, gown, and protective eyewear

10. A client has experienced pulmonary embolism. The nurse would assess for which symptom, which is **most** commonly reported?
1. Hot, flushed feeling
2. Sudden chills and fever
3. Chest pain that occurs suddenly
4. Dyspnea when deep breaths are taken

11. A client who is human immunodeficiency virus (HIV)–positive has had a tuberculin skin test (TST). The nurse notes a 7-mm area of induration at the site of the skin test and interprets the result as which finding?
1. Positive
2. Negative
3. Inconclusive
4. Need for repeat testing

12. A client with acquired immunodeficiency syndrome (AIDS) has histoplasmosis. The nurse would assess the client for which expected finding?
1. Dyspnea
2. Headache
3. Weight gain
4. Hypothermia

13. The nurse provides discharge instructions to a client with pulmonary sarcoidosis. The nurse concludes that the client understands the information if the client indicates to report which **early** sign of exacerbation?
1. Fever
2. Fatigue
3. Weight loss
4. Shortness of breath

14. The nurse is taking the history of a client with occupational lung disease (silicosis). The nurse would ask the client whether the client wears which item during periods of exposure to silica particles?
1. Mask
2. Gown
3. Gloves
4. Eye protection

15. The nurse is instructing a hospitalized client with a diagnosis of emphysema about measures that will enhance the effectiveness of breathing during dyspneic periods. Which position would the nurse instruct the client to assume?
1. Sitting up in bed
2. Side-lying in bed
3. Sitting in a recliner chair
4. Sitting up and leaning on an overbed table

16. The community health nurse is conducting an educational session with community members regarding the signs and symptoms associated with tuberculosis. The nurse informs the participants that tuberculosis is considered as a diagnosis if which signs and symptoms are present? **Select all that apply.**
- ❑ 1. Dyspnea
- ❑ 2. Headache
- ❑ 3. Night sweats
- ❑ 4. A bloody, productive cough
- ❑ 5. A cough with the expectoration of mucoid sputum

17. The nurse performs an admission assessment on a client with a diagnosis of tuberculosis. The nurse would check the results of which diagnostic test that will confirm this diagnosis?
1. Chest x-ray
2. Bronchoscopy
3. Sputum culture
4. Tuberculin skin test

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 2

Rationale: This client has sustained a blunt or closed-chest injury. Basic symptoms of a closed pneumothorax are shortness of breath and chest pain. A larger pneumothorax may cause tachypnea, cyanosis, diminished breath sounds, and subcutaneous emphysema. Hyperresonance also may occur on the affected side. A sucking sound at the site of injury would be noted with an open chest injury.

Test-Taking Strategy: Focus on the **subject,** a blunt chest injury. Noting the word *blunt* will assist in eliminating option 4, which describes a sucking chest wound injury. Knowing that in a respiratory injury increased respirations will occur will assist you in eliminating option 1. Option 3 can be eliminated because a barrel chest is a characteristic finding in a client with chronic obstructive pulmonary disease.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 523; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 447.

2. *Answer:* 2, 3

Rationale: Clinical manifestations of chronic obstructive pulmonary disease (COPD) include hypoxemia, hypercapnia, dyspnea on exertion and at rest, oxygen desaturation with exercise, and the use of accessory muscles of respiration. Chest x-rays reveal a hyperinflated chest and a flattened diaphragm if the disease is advanced. Pulmonary function tests will demonstrate decreased vital capacity.

Test-Taking Strategy: Focus on the **subject,** manifestations of COPD. Think about the pathophysiology associated with this disorder. Remember that hypercapnia, a hyperinflated chest, a flat diaphragm, oxygen desaturation on exercise, and decreased vital capacity are manifestations.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 564-565.

3. *Answer:* 1, 3, 4, 5

Rationale: The nurse would provide the client and family with information about tuberculosis and allay concerns about the contagious aspect of the infection. The client needs to follow the medication regimen exactly as prescribed and always have a supply of the medication on hand. Side and adverse effects of the medication and ways of minimizing them to ensure compliance need to be explained. After 2 to 3 weeks of medication therapy, it is unlikely that the client will infect anyone. Activities need to be resumed gradually, and a well-balanced diet that is rich in iron, protein, and vitamin C to promote healing and prevent recurrence of infection needs to be consumed. Respiratory isolation is not necessary, because family members already have been exposed. Instruct the client about thorough handwashing, to cover the mouth and nose when coughing or sneezing, and to put used tissues into plastic bags. A sputum culture is needed every 2 to 4 weeks once medication therapy is initiated. When the results of three sputum cultures are negative, the client is no longer considered infectious and can usually return to former employment.

Test-Taking Strategy: Focus on the **subject,** home care instructions for tuberculosis. Knowledge regarding the pathophysiology, transmission, and treatment of tuberculosis is needed to answer this question. Read each option carefully to answer correctly.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 578, 580.

4. *Answer:* 3

Rationale: If a biopsy was performed during a bronchoscopy, blood-streaked sputum is expected for several hours. Frank blood indicates hemorrhage. A dry cough may be expected. The client needs to be assessed for signs of complications, which would include cyanosis, dyspnea, stridor, bronchospasm, hemoptysis, hypotension, tachycardia, and dysrhythmias. Hematuria is unrelated to this procedure.

Test-Taking Strategy: Note the **strategic word,** *immediately*. Eliminate option 2 first because it is unrelated to the procedure. Next, eliminate option 1, because a dry cough may be expected. Noting that a biopsy has been performed will assist in eliminating option 4, because blood-streaked sputum would be expected. Note that the correct option relates to the airway.

References: Pagana, K., Pagana, T., & Pagana, T.N. (2021). *Mosby's diagnostic and laboratory test reference.* (15th ed.). St. Louis: Elsevier. p. 188.

5. *Answer:* 4

Rationale: Rib fractures result from a blunt injury or a fall. Typical signs and symptoms include shallow respirations, splinting or guarding the chest protectively to minimize chest movement, pain and tenderness localized at the fracture site that is exacerbated by inspiration and palpation, and possible bruising at the fracture site. Paradoxical respirations are seen with flail chest.

Test-Taking Strategy: Focus on the **subject,** findings associated with a rib fracture. Noting that the client sustained an injury and focusing on the anatomical location of the injury will direct you to the correct option.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 522; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 445.

6. *Answer:* 3

Rationale: Flail chest results from multiple rib fractures. This results in a "floating" section of ribs. Because this section is unattached to the rest of the bony rib cage, this segment results in paradoxical chest movement. This means that the force of inspiration pulls the fractured segment inward, while the rest of the chest expands. Similarly, during exhalation, the segment balloons outward while the rest of the chest moves inward. This is a characteristic sign of flail chest.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Note the **strategic word,** *most.* Cyanosis and hypotension occur with many different disorders, so eliminate options 1 and 2 first. From the remaining options, choose paradoxical chest movement over dyspnea on exhalation by remembering that a flail chest has broken rib segments that move independently of the rest of the rib cage.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 607.

7. *Answer:* 4
Rationale: The earliest detectable sign of acute respiratory distress syndrome is an increased respiratory rate, which can begin from 1 to 96 hours after the initial insult to the body. This is followed by increasing dyspnea, air hunger, retraction of accessory muscles, and cyanosis. Breath sounds may be clear or consist of fine inspiratory crackles or diffuse coarse crackles.
Test-Taking Strategy: Note the **strategic word,** *earliest*. Eliminate option 3 first, because intercostal retraction is a later sign of respiratory distress. Of the remaining options, recall that adventitious breath sounds (options 1 and 2) would occur later than an increased respiratory rate.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1591-1592.

8. *Answer:* 4
Rationale: The client is continued on medication therapy for up to 12 months, depending on the situation. The client generally is considered noncontagious after 2 to 3 weeks of medication therapy. The client is instructed to wear a mask if there will be exposure to crowds until the medication is effective in preventing transmission. The client is allowed to return to work when the results of three sputum cultures are negative.
Test-Taking Strategy: Focus on the **subject,** client understanding of medication therapy. Knowing that the medication therapy lasts for up to 12 months helps you eliminate option 1 first. Knowing that three sputum cultures must be negative helps you eliminate option 3 next. From the remaining options, recalling that the client is not contagious after 2 to 3 weeks of therapy will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 580.

9. *Answer:* 2
Rationale: The nurse who is in contact with a client with tuberculosis needs to wear an individually fitted particulate respirator. The nurse also would wear gloves as per standard precautions. The nurse wears a gown when the possibility exists that the clothing could become contaminated, such as when giving a bed bath.
Test-Taking Strategy: Focus on the **subject,** precautions when caring for the client with tuberculosis. Think about the nurse's task, a bed bath. Knowing that the nurse needs to wear a particulate respirator eliminates options 1 and 4. Knowledge of basic standard precautions directs you to the correct option.
Reference: Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. p. 438.

10. *Answer:* 3
Rationale: The most common initial symptom in pulmonary embolism is chest pain that is sudden in onset. The next most commonly reported symptom is dyspnea, which is accompanied by an increased respiratory rate. Other typical symptoms of pulmonary embolism include apprehension and restlessness, tachycardia, cough, and cyanosis.
Test-Taking Strategy: Note the **strategic word,** *most.* Because pulmonary embolism does not result from an infectious process or an allergic reaction, eliminate options 1 and 2 first. To select between the correct option and option 4, look at them closely. Option 4 states dyspnea when deep breaths are taken. Although dyspnea commonly occurs with pulmonary embolism, dyspnea is not associated only with deep breathing. Therefore, eliminate option 4.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 588.

11. *Answer:* 1
Rationale: The client with HIV infection is considered to have positive results on tuberculin skin testing with an area of induration larger than 5 mm. The client without HIV is positive with an induration larger than 10 mm. The client with HIV is immunosuppressed, making a smaller area of induration positive for this type of client. It is possible for the client infected with HIV to have false-negative readings because of the immunosuppression factor. Options 2, 3, and 4 are incorrect interpretations.
Test-Taking Strategy: Eliminate options 3 and 4 first because they are **comparable or alike.** From the remaining options, recalling that the client with HIV infection is immunosuppressed will assist in determining the interpretation of the area of induration.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 577.

12. *Answer:* 1
Rationale: Histoplasmosis is an opportunistic fungal infection that can occur in the client with AIDS. The infection begins as a respiratory infection and can progress to disseminated infection. Typical signs and symptoms include fever, dyspnea, cough, and weight loss. Enlargement of the client's lymph nodes, liver, and spleen may occur as well.
Test-Taking Strategy: Focus on the **subject,** manifestations of histoplasmosis. Recalling that histoplasmosis is an infectious process will help you eliminate option 4. Because the client has AIDS and another infection, weight gain is an unlikely symptom and can be eliminated next. Knowing that histoplasmosis begins as a respiratory infection helps you choose dyspnea over headache as the correct option.

Telegram & Insta: NCLEX_RN_Edu

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 332.

13. *Answer:* 4

Rationale: Dry cough and dyspnea are typical early manifestations of pulmonary sarcoidosis. Later manifestations include night sweats, fever, weight loss, and skin nodules.

Test-Taking Strategy: Note the **strategic word,** *early*. Because sarcoidosis is a pulmonary problem, eliminate options 1 and 3 first. Select the correct option over option 2 because the shortness of breath (and impaired ventilation) appears first and would cause the fatigue as a secondary symptom.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 532.

14. *Answer:* 1

Rationale: Silicosis results from chronic, excessive inhalation of particles of free crystalline silica dust. The client needs to wear a mask to limit inhalation of this substance, which can cause restrictive lung disease after years of exposure. Options 2, 3, and 4 are not necessary.

Test-Taking Strategy: Focus on the **subject,** prevention of silicosis. Recalling that exposure to silica dust causes the illness and that the dust is inhaled into the respiratory tract will direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 516-517.

15. *Answer:* 4

Rationale: Positions that will assist the client with emphysema with breathing include sitting up and leaning on an overbed table, sitting up and resting the elbows on the knees, and standing and leaning against the wall.

Test-Taking Strategy: Eliminate options 1 and 3 first because they are **comparable or alike.** Next, eliminate option 2 because this position will not enhance breathing.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 544-545.

16. *Answer:* 1, 3, 4, 5

Rationale: Tuberculosis should be considered for any client with a persistent cough with mucoid sputum production, weight loss, anorexia, night sweats, hemoptysis, shortness of breath, fever, or chills. The client's previous exposure to tuberculosis needs to also be assessed and correlated with the clinical manifestations.

Test-Taking Strategy: Note the **subject,** clinical manifestations of tuberculosis. Note that headache is not specifically associated with tuberculosis, is not respiratory in nature, and is not associated with an infection to assist in eliminating this option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 510-511.

17. *Answer:* 3

Rationale: Tuberculosis is definitively diagnosed through culture and isolation of *Mycobacterium tuberculosis*. A presumptive diagnosis is made based on a tuberculin skin test, a sputum smear that is positive for acid-fast bacteria, a chest x-ray, and histological evidence of granulomatous disease on biopsy.

Test-Taking Strategy: Focus on the **subject,** confirming the diagnosis of tuberculosis. Confirmation is made by identifying the bacteria, *M. tuberculosis.*

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 578.

CHAPTER 52

Respiratory Medications

Contributors: Jessica Grimm, DNP, APRN, ACNP-BC, CNE
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS Gas Exchange; Infection

I. Medication Inhalation Devices

A. Metered-dose inhaler (MDI): Uses a chemical propellant to push the medication out of the inhaler (Fig. 52.1)

B. Dry powder inhaler (DPI): Delivers medication without using chemical propellants, but it requires strong and fast inhalation.

C. Nebulizer: Delivers fine liquid mists of medication through a tube or a mask that fits over the nose and mouth, or with a mouthpiece, using air or oxygen under pressure

D. If two different inhaled medications are prescribed and one of the medications contains a glucocorticoid (corticosteroid), administer the bronchodilator first and the corticosteroid second.

If two different inhaled medications are prescribed, instruct the client to wait 5 minutes following administration of the first before inhaling the second. If a second dose of the same medication is needed, instruct the client to wait 1 to 2 minutes before taking the second dose.

II. Bronchodilators (Box 52.1)

A. Description

1. Sympathomimetic bronchodilators relax the smooth muscle of the bronchi and dilate the airways of the respiratory tree, making air exchange and respiration easier for the client. Examples include β_2-adrenergic agonists, such as albuterol.
2. Methylxanthine bronchodilators stimulate the central nervous system (CNS) and respiration, dilate coronary and pulmonary vessels, cause diuresis, and relax smooth muscle. An example is theophylline.
3. Used to treat acute bronchospasm, acute and chronic asthma, bronchitis, restrictive airway diseases, and reactive airway diseases
4. Contraindicated in individuals with hypersensitivity, peptic ulcer disease, severe cardiac disease and cardiac dysrhythmias, uncontrolled hypertension, high risk for stroke, hyperthyroidism, or uncontrolled seizure disorders
5. Used with caution in clients with hypertension, diabetes mellitus, or narrow-angle glaucoma. Caution is also required in use with other medications causing interactions, especially epinephrine because of the increase in blood glucose levels.
6. Theophylline increases the risk of digoxin toxicity and decreases the effects of lithium and phenytoin. Theophylline should be a last-line medication.
7. If theophylline and a β_2-adrenergic agonist are administered together, cardiac dysrhythmias may result.
8. Beta blockers, cimetidine, and erythromycin increase the effects of theophylline.
9. Barbiturates and carbamazepine decrease the effects of theophylline.

B. Side and adverse effects

1. Palpitations and tachycardia
2. Dysrhythmias
3. Restlessness, nervousness, tremors, seizures
4. Anorexia, nausea, and vomiting
5. Headaches and dizziness
6. Hyperglycemia
7. Mouth dryness and throat irritation with inhalers
8. Tolerance and paradoxical bronchoconstriction with inhalers

Telegram & Insta: NCLEX_RN_Edu

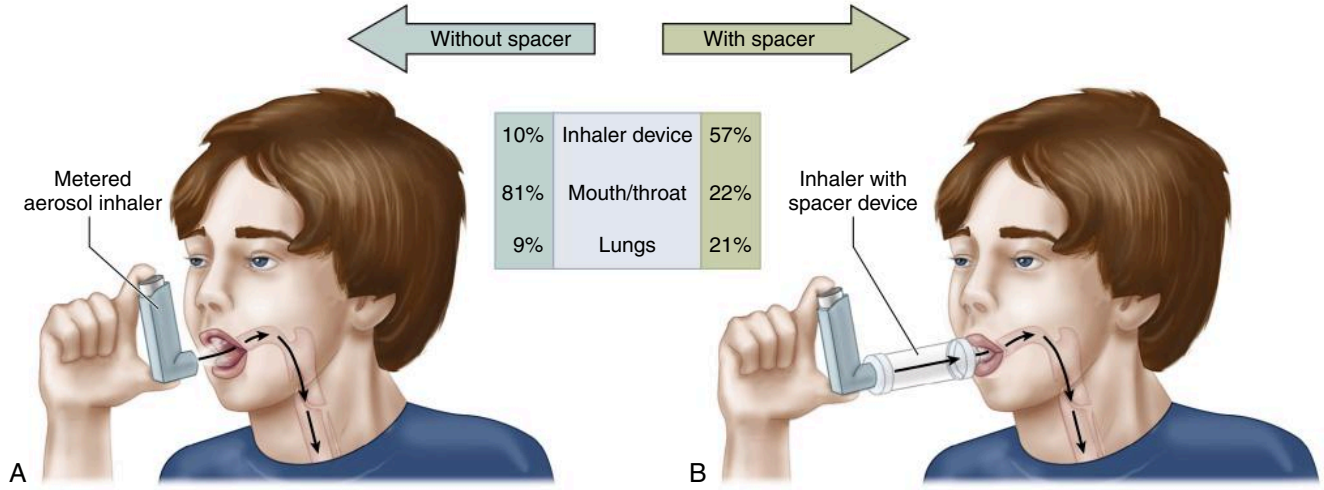

FIG. 52.1 Inhaled medications commonly used in asthma treatment include β-adrenergic bronchodilators, cromolyn sodium, and aerosol glucocorticoids. **A,** The metered-dose inhaler may be held about two finger widths (1.5 inches [4 cm]) in front of the mouth. **B,** Alternatively, an inhaler with a spacer device can be used. Clients should breathe deeply once before activating the inhaler and then continue breathing in for about 5 seconds. Clients then should hold their breath for 10 to 15 seconds before breathing out slowly. If a second dose is needed, clients should wait 1 to 2 minutes before taking the second dose.

BOX 52.1 Medications to Treat Restrictive Airway Problems

Bronchodilators

β_2-Adrenergic Agonists

Inhaled

- Albuterol
- Arformoterol
- Formoterol
- Levalbuterol
- Salmeterol

Oral

- Albuterol
- Terbutaline

Methylxanthines

- Aminophylline
- Theophylline, oral

Anticholinergics

- Aclidinium, inhaled
- Ipratropium, inhaled
- Revefenacin, inhaled
- Tiotropium, inhaled
- Umeclidinium, inhaled

Glucocorticoids (Corticosteroids)

Inhaled

- Beclomethasone dipropionate
- Budesonide
- Ciclesonide
- Fluticasone propionate
- Mometasone furoate

Oral

- Prednisolone
- Prednisone

Leukotriene Modifiers

- Montelukast, oral
- Zafirlukast, oral
- Zileuton, oral

Inhaled Nonsteroidal Antiallergy Agent

- Cromolyn sodium, inhaled

Monoclonal Antibody

- Omalizumab

Adapted from Rosenthal, L., & Burchum, J. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 936, 941.

C. Interventions

1. Assess lung sounds.
2. Monitor for cardiac dysrhythmias.
3. Assess for cough, wheezing, decreased breath sounds, and sputum production.
4. Monitor for restlessness and confusion.
5. Provide adequate hydration.
6. Administer the medication at regular intervals around the clock to maintain a sustained therapeutic level.
7. Administer oral medications with or after meals to decrease gastrointestinal irritation.
8. Monitor for a therapeutic serum theophylline level of 10 to 20 mcg/mL (55.5 to 111 mcmol/L).
9. Intravenously administered theophylline preparations should be administered slowly and always via an infusion pump.
10. Client education
    a. Not to crush enteric-coated or sustained-release tablets or capsules
    b. To avoid caffeine-containing products such as coffee, tea, cola, and chocolate, and over-the-counter medications
    c. About the side and adverse effects of bronchodilators
    d. How to monitor the pulse and to report any abnormalities to the primary health care provider (PHCP)
    e. How to use an inhaler, spacer (see Fig. 52.1), or nebulizer and how to monitor the amount of medication remaining in an inhaler canister
    f. To carry the inhaler medication with them at all times because it can stop or reduce life-threatening bronchoconstriction
    g. The importance of smoking cessation and information regarding support resources
    h. To monitor blood glucose levels if diabetes mellitus is a coexisting condition
    i. To wear a MedicAlert bracelet, particularly if the client has asthma

Telegram & Insta: NCLEX_RN_Edu

Theophylline toxicity is likely to occur when the serum level is higher than 20 mcg/mL (111 mcmol/L). Early signs of toxicity include restlessness, nervousness, tremors, palpitations, and tachycardia.

III. Anticholinergics (see Box 52.1)

A. Inhaled medications that improve lung function by blocking muscarinic receptors in the bronchi, which prevents bronchoconstriction

B. Effective for treating chronic obstructive pulmonary disease, allergy-induced asthma, and exercise-induced bronchospasm

C. Side effects include dry mouth and irritation of the pharynx; sucking on sugarless candy will help relieve symptoms.

D. Systemic anticholinergic effects rarely occur but can include increased intraocular pressure, narrow-angle glaucoma, blurred vision, tachycardia, cardiovascular events, urinary retention, prostate enlargement, and constipation.

The client with a peanut allergy should not take certain ipratropium products because they contain soy lecithin, which is in the same plant family as peanuts.

IV. Glucocorticoids (Corticosteroids) (see Box 52.1)

A. Glucocorticoids act as antiinflammatory agents and reduce edema of the airways; they are used to treat asthma and other inflammatory respiratory conditions.

B. See Chapter 48 for information on glucocorticoids.

V. Leukotriene Modifiers (see Box 52.1)

A. Description

1. Used in the prophylaxis and treatment of chronic bronchial asthma (not used for acute asthma episodes)
2. Inhibit bronchoconstriction caused by specific antigens and reduce airway edema and smooth muscle constriction
3. Contraindicated in clients with hypersensitivity and in breast-feeding or chest-feeding
4. Should be used with caution in clients with impaired hepatic function
5. Coadministration of inhaled glucocorticoids increases the risk of upper respiratory infection.

B. Side and adverse effects

1. Headache
2. Nausea and vomiting
3. Dyspepsia
4. Diarrhea
5. Generalized pain, myalgia
6. Fever
7. Dizziness
8. Depression
9. Anxiety
10. Insomnia
11. Irritability
12. Suicidal thinking
13. Hallucinations

C. Interventions

1. Assess frequency of exacerbations.
2. Assess changes in lung function.
3. Assess liver function laboratory values.
4. Monitor for cyanosis.

D. Client education

1. To take medication 1 hour before or 2 hours after meals
2. Effectiveness requires continued use for at least 48 to 72 hours and depends on regular use
3. To increase fluid intake
4. Not to decrease the dose or discontinue the medication and to take it as prescribed, even during symptom-free periods
5. Teach the client how to use the inhaler using the teach-back method.

VI. Inhaled Nonsteroidal Antiallergy Agent (see Box 52.1)

A. Description

1. Antiasthmatic, antiallergic, and mast cell stabilizers inhibit mast cell release after exposure to antigens.
2. Used to treat allergic rhinitis, bronchial asthma, and exercise-induced bronchospasm
3. Contraindicated in clients with known hypersensitivity
4. Orally administered cromolyn sodium is used with caution in clients with impaired hepatic or renal function.

B. Side and adverse effects

1. Cough, sneezing, nasal sting, or bronchospasm following inhalation
2. Unpleasant taste in the mouth

C. Interventions: Monitor respirations and assess lung sounds for rhonchi or wheezing.

D. Client education

1. To administer oral capsules at least 30 minutes before meals
2. Not to discontinue the medication abruptly, because a rebound asthmatic attack can occur

Instruct the client taking inhaled medications to drink a few sips of water before and after inhalation to prevent a cough and an unpleasant taste in the mouth.

VII. Monoclonal Antibody (see Box 52.1)

A. Description

1. Omalizumab is a recombinant DNA-derived humanized immunoglobulin G (IgG) murine monoclonal antibody that selectively binds to immunoglobulin E (IgE) to limit the release of mediators in the allergic response.

Telegram & Insta: NCLEX_RN_Edu

2. Used to treat allergy-related asthma; administered subcutaneously every 2 to 4 weeks
3. Dose is titrated on the basis of the serum IgE level and body weight.
4. Contraindicated in those with hypersensitivity to the medication

B. Side and adverse effects
1. Injection site reactions
2. Viral infections
3. Upper respiratory infections
4. Sinusitis
5. Headache
6. Pharyngitis
7. Anaphylaxis
8. Malignancies

C. Interventions
1. Assess respiratory rate, rhythm, and depth, and auscultate lung sounds.
2. Assess for allergies and/or allergic reaction symptoms such as rash or urticaria.
3. Have medications for the treatment of severe hypersensitivity reactions available during initial administration in case anaphylaxis occurs.

D. Client education
1. That respiratory improvement will not be immediate
2. Not to stop taking or decrease the currently prescribed asthma medications unless instructed
3. To avoid receiving live virus vaccines for the duration of treatment
4. To increase fluid intake to decrease viscosity of pulmonary secretions
5. Perform return demonstration on proper injection techniques; each needle is used for only one injection.

VIII. Antihistamines (Box 52.2)

A. Description
1. Called *histamine antagonists* or *H_1 blockers*; these medications compete with histamine for receptor sites, thus preventing a histamine response.
2. When the H_1 receptor is stimulated, the extravascular smooth muscles, including those lining the nasal cavity, are constricted.
3. Decrease nasopharyngeal, gastrointestinal, and bronchial secretions by blocking the H_1 receptor
4. Used for the common cold, rhinitis, nausea and vomiting, motion sickness, urticaria, and as a sleep aid
5. Can cause CNS depression if taken with alcohol, opioids, hypnotics, or barbiturates, particularly with first-generation antihistamines
6. Should be used with caution in clients with chronic obstructive pulmonary disease because of their drying effect

BOX 52.2 Antihistamines

- Brompheniramine
- Cetirizine
- Chlorpheniramine
- Clemastine
- Cyproheptadine
- Desloratadine
- Dimenhydrinate
- Diphenhydramine
- Fexofenadine
- Levocetirizine
- Loratadine
- Olopatadine
- Tripolidine

7. Diphenhydramine has an anticholinergic effect and should be avoided in clients with narrow-angle glaucoma.

B. Side and adverse effects
1. Drowsiness and fatigue
2. Dizziness
3. Urinary retention
4. Blurred vision
5. Wheezing
6. Constipation
7. Dry mouth
8. Gastrointestinal irritation
9. Hypotension
10. Hearing disturbances
11. Photosensitivity
12. Nervousness and irritability
13. Confusion
14. Nightmares

C. Interventions
1. Monitor for signs of urinary dysfunction.
2. Administer with food or milk.
3. Avoid subcutaneous injection, and administer by intramuscular injection in a large muscle if the intramuscular route is prescribed.

D. Client education
1. To avoid hazardous activities, alcohol, and other CNS depressants
2. If the medication is being taken for motion sickness, take it 30 minutes before the event and then before meals and at bedtime during the event as prescribed.
3. To suck on hard candy or ice chips for dry mouth
4. To report palpitations, changes in heart rate, or changes in bowel or bladder habits

IX. Nasal Decongestants (Box 52.3)

A. Description
1. Include adrenergic, anticholinergic, and corticosteroid medications
2. Shrink nasal mucosal membranes and reduce fluid secretion
3. Used for allergic rhinitis, hay fever, and acute coryza (profuse nasal discharge)
4. Contraindicated or used with extreme caution in clients with hypertension, cardiac disease, hyper-

Telegram & Insta: NCLEX_RN_Edu

BOX 52.3 Nasal Decongestants

Nonglucocorticoids	Glucocorticoids
■ Oxymetazoline	■ Beclomethasone
■ Phenylephrine hydrochloride	■ Budesonide
■ Pseudoephedrine hydrochloride	■ Ciclesonide
	■ Flunisolide
	■ Fluticasone propionate
	■ Fluticasone furoate
	■ Mometasone
	■ Triamcinolone

thyroidism, diabetes mellitus, hepatic or renal disease

B. Side and adverse effects
1. Nervousness, headache, irritability
2. Restlessness, insomnia
3. Hypertension
4. Hyperglycemia
5. Palpitations
6. Dysuria

C. Interventions
1. Monitor for cardiac dysrhythmias.
2. Monitor blood glucose levels.

D. Client education

Nasal decongestants can cause tolerance and rebound nasal congestion (vasodilation) caused by irritation of the nasal mucosa. Therefore, the client needs to be informed that these medications should not be used for longer than 48 hours.

1. To avoid consuming caffeine in large amounts because it can increase restlessness and palpitations
2. About the importance of limiting the use of nasal sprays and drops to prevent rebound nasal congestion; consider weaning off one naris at a time to prevent this.

X. Expectorants and Mucolytic Agents (Box 52.4)

A. Description
1. Expectorants loosen bronchial secretions so that they can be eliminated with coughing; they are used for a dry unproductive cough and to stimulate bronchial secretions.
2. Mucolytic agents thin mucous secretions to help make the cough more productive.
3. Mucolytic agents with dextromethorphan should not be used by clients with chronic obstructive pulmonary disease because they suppress the cough.
4. Acetylcysteine can increase airway resistance and should not be used in clients with asthma. This medication can also be used to prevent liver damage in acetaminophen overdose, as well as to protect the kidneys in the event that diagnostic testing requiring contrast dye is done.

B. Side and adverse effects
1. Gastrointestinal irritation
2. Rash
3. Oropharyngeal irritation

C. Interventions
1. Acetylcysteine, administered by nebulization, should not be mixed with another medication.
2. If acetylcysteine is administered with a bronchodilator, the bronchodilator should be administered 5 minutes before the acetylcysteine.
3. Monitor for side effects of acetylcysteine such as nausea and vomiting, stomatitis, and runny nose.

D. Client education
1. To take the medication with a full glass of water to loosen mucus. Encourage fluid intake up to 3000 mL per day unless contraindicated.
2. To avoid alcohol and products containing alcohol
3. To maintain adequate fluid intake
4. To cough and deep-breathe
5. To take medication with food to prevent GI upset

BOX 52.4 Expectorants and Mucolytic Agents

Expectorant	Mucolytic
■ Guaifenesin	■ Acetylcysteine

XI. Antitussives (Box 52.5)

A. Description: Act on the cough control center in the medulla to suppress the cough reflex; used for a cough that is nonproductive and irritating

B. Side and adverse effects
1. Dizziness, drowsiness, sedation
2. Gastrointestinal irritation, nausea
3. Dry mouth
4. Constipation
5. Respiratory depression

C. Interventions
1. Encourage the client to take adequate fluids with the medication.
2. Encourage the client to sleep with the head of the bed elevated.
3. Note that medication dependency can occur.
4. Avoid administration to the client with a head injury or a postoperative cranial surgery client.
5. Avoid administration to the client using opioids, sedative-hypnotics, barbiturates, or select

Telegram & Insta: NCLEX_RN_Edu

BOX 52.5 Antitussives

Opioids
- Codeine phosphate, codeine sulfate
- Hydrocodone

Nonopioids
- Benzonatate
- Dextromethorphan

BOX 52.6 Opioid Antagonists
- Alvimopan
- Methylnaltrexone
- Naloxegol
- Naloxone
- Naldemedine
- Naltrexone

BOX 52.7 First-Line and Second-Line Medications for Tuberculosis

First-Line Agents
- Ethambutol
- Isoniazid
- Pyrazinamide
- Rifampin

Second-Line Agents
- Amikacin
- Capreomycin sulfate
- Cycloserine
- Ethionamide
- Levofloxacin
- Moxifloxacin
- *p*-Aminosalicylic acid
- Rifabutin
- Rifapentine
- Streptomycin

antidepressants, because CNS depression can occur.

D. Client education
1. If the cough lasts longer than 1 week and a fever or rash occurs, to notify the PHCP
2. To avoid hazardous activities
3. To avoid the use of alcohol

XII. Opioid Antagonists (Box 52.6)

A. Description
1. Reverse respiratory depression in opioid overdose
2. Avoid their use for nonopioid respiratory depression.
3. Recurrence of respiratory depression can occur if the duration of the opiate exceeds the duration of the opioid antagonist.
4. This medication may be prescribed for clients at risk for opioid overdose.

B. Side and adverse effects
1. Nausea, vomiting
2. Tremors
3. Sweating
4. Increased blood pressure
5. Tachycardia

C. Interventions
1. Assess vital signs, especially respirations.
2. For intravenous administration, the dose is titrated every 2 to 5 minutes as prescribed.
3. Have oxygen and resuscitative equipment available during administration.

XIII. Tuberculosis Medications (Box 52.7)

A. Description
1. Offer the most effective method for treating the disease and preventing transmission
2. Treatment of identified lesions depends on whether the individual has active disease or has only been exposed to the disease.
3. Treatment is difficult because the bacterium has a waxy substance on the capsule that makes penetration and destruction difficult.
4. The use of a multidrug regimen destroys organisms as quickly as possible and minimizes the emergence of drug-resistant organisms.
5. Active tuberculosis is treated with a combination of medications to which the organism is susceptible.
6. Individuals with active tuberculosis are treated for 6 to 9 months; however, clients with immunosuppression (e.g., HIV) are treated for a longer period.
7. After the infected individual has received medication for 2 to 3 weeks, the risk of transmission is greatly reduced.
8. Most clients have negative sputum cultures after 3 months of compliance with medication therapy.
9. Individuals who have been exposed to active tuberculosis are treated with preventive isoniazid for 9 to 12 months.

B. First-line or second-line medications
1. First-line medications provide the most effective antituberculosis activity.
2. Second-line medications are used in combination with first-line medications but are more toxic.
3. Current infecting organisms are proving resistant to standard first-line medications; the resistant organisms develop because individuals with the disease fail to complete the course of treatment, so surviving bacteria adapt to the medication and become resistant.
4. Multidrug therapies are instituted because of the resistant organisms.

Telegram & Insta: NCLEX_RN_Edu

C. Multidrug-resistant strain of tuberculosis (MDR-TB)

1. Resistance occurs when a client receiving two medications (first-line and second-line medications) discontinues one of the medications.
2. The client briefly experiences some response from the single medication, but then large numbers of resistant organisms begin to grow.
3. The client, infectious again, transmits the drug-resistant organism to other individuals.
4. As this event is repeated, an organism develops that is resistant to many of the first-line tuberculosis medications.

D. General client education points for tuberculosis medications

1. Not to skip doses and to take medication for the full length of the prescribed therapy
2. Not to take any other medication without consulting the PHCP
3. About the importance of follow-up PHCP visits and laboratory tests
4. To avoid alcohol
5. To take medication on an empty stomach with 8 oz of water 1 hour before or 2 hours after meals and to avoid taking antacids with the medication
6. About the adverse effects that require PHCP notification
7. First-line medications to treat TB all can damage the liver; therefore, alcohol should be avoided during the entire duration of therapy.
8. Inform the client about direct observed therapy (DOT) or video direct observed therapy (VDOT) to ensure adherence to the medication regimen.

XIV. First-Line Medications for Tuberculosis (see Box 52.7)

A. Isoniazid (see Clinical Judgment: Evaluate Outcomes Box)

1. Description
   - **a.** Bactericidal
   - **b.** Inhibits the synthesis of mycolic acids and acts to kill actively growing organisms in the extracellular environment
   - **c.** Inhibits the growth of dormant organisms in the macrophages and caseating granulomas
   - **d.** Is active only during cell division and is used in combination with other antitubercular medications
2. Contraindications and cautions
   - **a.** Contraindicated in clients with hypersensitivity or with acute liver disease
   - **b.** Use with caution in clients with chronic liver disease, alcoholism, or renal impairment.
   - **c.** Use with caution in clients taking nicotinic acid.
   - **d.** Use with caution in clients taking hepatotoxic medications because the risk for hepatotoxicity increases.
   - **e.** Use with caution in clients with diabetes mellitus.
   - **f.** Alcohol increases the risk of hepatotoxicity.
   - **g.** May increase the risk of toxicity of carbamazepine and phenytoin, causing phenytoin levels to rise; phenytoin dosage may need to be reduced based on plasma levels.
   - **h.** May decrease ketoconazole concentrations
3. Side and adverse effects
   - **a.** Hypersensitivity reactions
   - **b.** Peripheral neuritis
   - **c.** Neurotoxicity
   - **d.** Hepatotoxicity and hepatitis; increased liver function test levels
   - **e.** Pyridoxine deficiency
   - **f.** Irritation at injection site with intramuscular administration
   - **g.** Nausea and vomiting
   - **h.** Dry mouth
   - **i.** Dizziness
   - **j.** Hyperglycemia
   - **k.** Vision changes
4. Interventions
   - **a.** Assess for hypersensitivity.
   - **b.** Obtain a chest radiograph and sputum cultures to evaluate therapeutic effects.
   - **c.** Assess for hepatic dysfunction.
   - **d.** Assess for sensitivity to nicotinic acid.
   - **e.** Monitor liver function test results.
   - **f.** Monitor for signs of nonviral hepatitis, such as anorexia, nausea, vomiting, weakness, fatigue, dark urine, or jaundice; if these symptoms occur, withhold the medication and notify the PHCP; liver function tests would be done and elevations in the results could also be an indication of nonviral hepatitis.
   - **g.** Monitor for tingling, numbness, or burning of the extremities.
   - **h.** Assess mental status.
   - **i.** Monitor for visual changes, and notify the PHCP if they occur.
   - **j.** Assess for dizziness and initiate safety precautions.
   - **k.** Monitor complete blood count (CBC) and blood glucose levels.
   - **l.** Administer isoniazid 1 hour before or 2 hours after a meal, because food may delay absorption.
   - **m.** Administer isoniazid at least 1 hour before antacids, and take the medication with meals if gastrointestinal upset occurs.
   - **n.** Administer pyridoxine as prescribed to reduce the risk of neurotoxicity.

Telegram & Insta: NCLEX_RN_Edu

Many tuberculosis medications can cause toxic effects, such as hepatotoxicity, nephrotoxicity, neurotoxicity, optic neuritis, or ototoxicity. Teach the client about the signs of toxicity, and inform the client that the PHCP needs to be notified if any signs arise.

5. Client education
   a. To avoid tyramine-containing foods because they may cause a reaction such as red and itching skin, a pounding heartbeat, lightheadedness, a hot or clammy feeling, or a headache; if this occurs, the client should notify the PHCP.
   b. To recognize the signs of neurotoxicity, hepatitis, and hepatotoxicity
   c. To notify the PHCP if signs of neurotoxicity, hepatitis and hepatotoxicity, or visual changes occur

CLINICAL JUDGMENT: EVALUATE OUTCOMES

The nurse is monitoring a client who has been taking isoniazid for the past 4 months to treat tuberculosis for a response to the medication. The nurse determines that the client is experiencing nonviral hepatitis as an adverse effect based on the following client manifestations:

- Anorexia
- Dark-colored urine
- Fatigue
- Jaundice
- Nausea
- Weakness

B. Rifampin
1. Description
   a. Inhibits bacterial RNA synthesis
   b. Binds to DNA-dependent RNA polymerase and blocks RNA transcription
   c. Used with at least one other antitubercular medication
2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity
   b. Used with caution in clients with hepatic dysfunction or alcoholism
   c. Use of alcohol or hepatotoxic medications may increase the risk of hepatotoxicity.
   d. Decreases the effects of several medications, including oral anticoagulants, oral hypoglycemics, chloramphenicol, digoxin, disopyramide phosphate, mexiletine, quinidine polygalacturonate, fluconazole, methadone hydrochloride, phenytoin, and verapamil hydrochloride
3. Side and adverse effects
   a. Hypersensitivity reaction, including fever, chills, shivering, headache, muscle and bone pain, dyspnea, drowsiness, anxiety, confusion
   b. Heartburn, nausea, vomiting, diarrhea
   c. Red-orange–colored body secretions
   d. Vision changes
   e. Hepatotoxicity and hepatitis
   f. Increased uric acid levels
   g. Blood dyscrasias
   h. Colitis
4. Interventions
   a. Assess for hypersensitivity.
   b. Obtain a chest radiograph and sputum cultures to evaluate therapeutic effects.
   c. Evaluate CBC, uric acid, and liver function test results.
   d. Assess for signs of hepatitis; if they occur, withhold the medication and notify the PHCP.
   e. Monitor for signs of colitis.
   f. Assess for visual changes.
   g. Advise those taking oral contraceptives to use a nonhormonal form of birth control.
5. Client education
   a. That urine, feces, sweat, and tears will be red-orange and that soft contact lenses can become permanently discolored
   b. To notify the PHCP if jaundice (yellow eyes or skin) develops or if weakness, fatigue, nausea, vomiting, sore throat, fever, or unusual bleeding occurs; to avoid alcohol

C. Ethambutol
1. Description
   a. Bacteriostatic
   b. Interferes with cell metabolism and multiplication by inhibiting one or more metabolites in susceptible organisms
   c. Inhibits bacterial RNA synthesis and is active only during cell division
   d. Slow-acting and must be used with other bactericidal agents
2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity or optic neuritis and in children younger than 13 years
   b. Used with caution in clients with renal dysfunction, gout, ocular defects, diabetic retinopathy, cataracts, or ocular inflammatory conditions
   c. Used with caution in clients taking neurotoxic medications because the risk for neurotoxicity increases
   d. Used with caution in pregnancy and in breast-feeding or chest-feeding
3. Side and adverse effects
   a. Hypersensitivity reactions
   b. Anorexia, nausea, vomiting

Telegram & Insta: NCLEX_RN_Edu

c. Dizziness
d. Malaise
e. Mental confusion
f. Joint pain
g. Dermatitis
h. Optic neuritis
i. Peripheral neuritis
j. Thrombocytopenia
k. Increased uric acid levels
l. Anaphylactoid reaction

4. Interventions
a. Assess the client for hypersensitivity.
b. Obtain a chest radiograph and sputum cultures to evaluate therapeutic effects.
c. Evaluate results of CBC, uric acid, and renal and liver function tests.
d. Monitor for visual changes, such as altered color perception and decreased visual acuity; if changes occur, withhold the medication and notify the PHCP.
e. Administer once every 24 hours, and administer with food to decrease gastrointestinal upset.
f. Monitor uric acid concentration, and assess for painful or swollen joints or signs of gout.
g. Monitor intake and output and for adequate renal function.
h. Assess mental status.
i. Monitor for dizziness, and initiate safety precautions.
j. Assess for peripheral neuritis (numbness, tingling, or burning of the extremities); if it occurs, notify the PHCP.

5. Client education
a. That nausea, related to the medication, can be prevented by taking the daily dose at bedtime or by taking the prescribed antinausea medications
b. That alcohol should be avoided
c. To notify the PHCP immediately if any visual problems occur or if a rash; swelling and pain in the joints; or numbness, tingling, or burning in the hands or feet occurs

D. Pyrazinamide

1. Description
a. The exact mechanism of action is unknown.
b. May be bacteriostatic or bactericidal, depending on its concentration at the infection site and on the susceptibility of the infecting organism
c. Used with at least one other antitubercular medication if ineffectiveness of the primary medication(s) occurs

2. Contraindications and cautions
a. Contraindicated in clients with hypersensitivity
b. Used with caution in clients with diabetes mellitus, renal or hepatic impairment, or gout and in children
c. May decrease the effects of allopurinol, colchicine, and probenecid
d. Cross-sensitivity is possible with isoniazid, ethionamide, or nicotinic acid.

3. Side and adverse effects
a. Increases liver function tests and uric acid levels
b. Arthralgia, myalgia
c. Photosensitivity
d. Hepatotoxicity
e. Thrombocytopenia

4. Interventions
a. Assess for hypersensitivity.
b. Obtain a chest radiograph and sputum cultures to evaluate therapeutic effects.
c. Evaluate CBC, liver function test results, and uric acid levels.
d. Observe for hepatotoxic effects; if they occur, withhold the medication and notify the PHCP.
e. Assess for painful or swollen joints.
f. Evaluate blood glucose level, because diabetes mellitus may be difficult to control while the client is taking the medication.

5. Client education
a. To take the medication with food to reduce gastrointestinal distress
b. To take all medication, not to skip doses, and to complete the full length of therapy
c. To avoid sunlight or ultraviolet light until photosensitivity is determined

⚠ Some tuberculosis medications can cause red-orange–colored body secretions. Inform the client that this is not a harmful effect but that the secretions can stain and permanently discolor items.

XV. Second-Line Medications for Tuberculosis (see Box 52.7)

A. Rifabutin

1. Description
a. Inhibits mycobacterial DNA-dependent RNA polymerase and suppresses protein synthesis
b. Used to prevent disseminated *Mycobacterium avium* complex (MAC) disease in clients with advanced HIV infection
c. Used to treat active MAC disease and tuberculosis in clients with HIV infection

2. Cautions
a. Can affect blood levels of some medications, including oral contraceptives and some medications used to treat HIV infection

Telegram & Insta: NCLEX_RN_Edu

b. A nonhormonal method of birth control should be used instead of an oral contraceptive.

3. Side and adverse effects
   a. Rash
   b. Gastrointestinal disturbances
   c. Neutropenia
   d. Red-orange–colored body secretions
   e. Uveitis
   f. Myositis
   g. Arthralgia
   h. Hepatitis
   i. Chest pain with dyspnea
   j. Flulike syndrome
   k. Anxiety, confusion, insomnia
4. Interventions
   a. Observe for hepatotoxic effects; if they occur, withhold the medication and notify the PHCP.
   b. Assess for painful or swollen joints.
   c. Assess for ocular pain or blurred vision.
5. Client education
   a. That the medication can be taken without regard to food
   b. To notify the PHCP for any flulike symptoms

B. Rifapentine
1. Description: Used only for pulmonary tuberculosis
2. Cautions: Can affect blood levels of some medications, including oral contraceptives, warfarin, and some medications used to treat HIV infection
3. Side and adverse effects
   a. Red-orange–colored body secretions
   b. Hepatotoxicity
   c. Headache
   d. Fatigue
   e. Anxiety
   f. Dizziness
   g. Visual disturbances
   h. Nausea, vomiting, heartburn
4. Interventions
   a. Obtain baseline liver function studies and assess throughout therapy.
   b. Observe for hepatotoxic effects and renal injury; if they occur, withhold the medication and notify the PHCP.
5. Client education
   a. That the medication can be taken without regard to food
   b. To avoid sunlight or ultraviolet light until photosensitivity is determined
   c. That red-orange–colored body secretions may occur
   d. To report any flulike symptoms to the PHCP

C. Capreomycin sulfate
1. Description
   a. Mechanism of action is unknown.
   b. Used to treat MDR-TB when significant resistance to other medications is expected
   c. Administered intramuscularly
2. Contraindications and cautions
   a. The risk of nephrotoxicity, ototoxicity, and neuromuscular blockade is increased with the use of aminoglycosides or loop diuretics.
   b. Used with caution in clients with renal insufficiency, acoustic nerve impairment, hepatic disorder, myasthenia gravis, or parkinsonism
   c. Not administered to clients receiving streptomycin
3. Side and adverse effects
   a. Nephrotoxicity
   b. Ototoxicity
   c. Neuromuscular blockade
4. Interventions
   a. Perform baseline audiometric testing.
   b. Assess renal, hepatic, and electrolyte levels before administration.
   c. Monitor intake and output.
   d. Reconstituted medication may be stored for 48 hours at room temperature.
   e. Administer intramuscularly, deep into a large muscle mass.
   f. Rotate injection sites.
   g. Observe injection site for redness, excessive bleeding, and inflammation.
5. Client education
   a. Not to perform tasks that require mental alertness
   b. To report any hearing loss, balance disturbances, respiratory difficulty, weakness, or signs of hypersensitivity reactions

D. Antibiotics
1. Description
   a. Aminoglycoside antibiotics or fluoroquinolones are given with at least one other antitubercular medication.
   b. Bactericidal because of receptor-binding action interfering with protein synthesis in susceptible microorganisms
   c. Gastrointestinal disturbances are the most common side effect.
   d. Fluoroquinolones are not recommended for use in children.
2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity, neuromuscular disorders, or eighth cranial nerve damage
   b. Used with caution in the older client, in neonates because of renal insufficiency and immaturity, and in young infants because it may cause CNS depression
   c. The risk of toxicity increases if taken with other aminoglycosides or nephrotoxicity- or ototoxicity-producing medications.

Telegram & Insta: NCLEX_RN_Edu

3. Side and adverse effects
   a. Hypersensitivity
   b. Pain and irritation at the injection site
   c. Nephrotoxicity is indicated by increased blood urea nitrogen and serum creatinine levels.
   d. Ototoxicity is indicated by tinnitus, dizziness, ringing or roaring in the ears, and reduced hearing.
   e. Neurotoxicity is indicated by headache, dizziness, lethargy, tremors, and visual disturbances.
   f. Superinfections
   g. Interactions between other medications, such as oral contraceptives.
4. Interventions
   a. Assess for hypersensitivity.
   b. Monitor for ototoxic, neurotoxic, and nephrotoxic reactions.
   c. Monitor liver and renal function test results.
   d. Obtain baseline audiometric test and repeat every 1 to 2 months, because the medication impairs the eighth cranial nerve.
   e. Assess acuteness of hearing.
   f. Monitor for visual changes.
   g. Assess hydration status and maintain adequate hydration during therapy.
   h. Monitor intake and output.
   i. Assess urinalysis.
   j. Monitor for superinfection.
   k. May cause discoloration of the permanent teeth and tooth enamel in fetuses and children.
5. Client education:
   a. To notify the PHCP if hearing loss, changes in vision, or urinary problems occur
   b. To take the entire course as directed
   c. Provide the client with a list of foods and beverages that may interact negatively with antibiotics, such as alcohol, acidic fruit, juices, and dairy products.

E. Ethionamide
1. Description
   a. Mechanism of action is unknown.
   b. Used to treat MDR-TB when significant resistance to other medications is expected
2. Contraindications and cautions
   a. Contraindicated in clients with hypersensitivity
   b. Used with caution in clients with diabetes mellitus or renal dysfunction
3. Side and adverse effects
   a. Anorexia, nausea, vomiting
   b. Metallic taste in the mouth
   c. Orthostatic hypotension
   d. Jaundice
   e. Mental changes
   f. Seizures
   g. Peripheral neuritis
   h. Rash
4. Interventions
   a. Assess liver and renal function test results.
   b. Monitor glucose levels in the client with diabetes mellitus.
   c. Administer pyridoxine as prescribed to reduce the risk of neurotoxicity.
5. Client education
   a. To take medication with food or meals to minimize gastrointestinal irritation
   b. To change positions slowly
   c. To report signs of a rash, which can progress to exfoliative dermatitis if the medication is not discontinued

F. Aminosalicylic acid
1. Description
   a. Inhibits folic acid metabolism in mycobacteria
   b. Used to treat MDR-TB when significant resistance to other medications is expected
2. Contraindications and cautions
   a. Contraindicated with hypersensitivity to aminosalicylates, salicylates, or compounds containing the *para*-aminophenol group
   b. Aminobenzoates block the absorption of aminosalicylate sodium.
   c. Dose may be modified for renal impairment.
3. Side and adverse effects
   a. Hypersensitivity
   b. Bitter taste in the mouth
   c. Gastrointestinal tract irritation
   d. Exfoliative dermatitis
   e. Blood dyscrasias
   f. Crystalluria
   g. Changes in thyroid function
4. Interventions
   a. Assess for hypersensitivity.
   b. Offer water to rinse the mouth and chewing gum or hard candy to alleviate the bitter taste.
   c. Encourage fluid intake to prevent crystalluria.
   d. Monitor intake and output.
5. Client education
   a. To discard the medication and obtain a new supply if a purplish-brown discoloration occurs
   b. To take the medication with food
   c. That urine may turn red on contact with hypochlorite bleach if bleach was used to clean a toilet
   d. That contact lenses, urine, and skin may turn yellow or orange
   e. Not to take aspirin or over-the-counter medications without the PHCP's approval
   f. To report signs of a blood dyscrasia, such as sore throat or mouth, malaise, fatigue, bruising, or bleeding; blood counts should be obtained periodically.

Telegram & Insta: NCLEX_RN_Edu

G. Cycloserine
- **1.** Description
  - **a.** Interferes with cell wall biosynthesis
  - **b.** Used to treat MDR-TB when significant resistance to other medications is expected
- **2.** Contraindications and cautions
  - **a.** Use of alcohol or ethionamide increases the risk of seizures
  - **b.** Used with caution in clients with a seizure disorder, depression, severe anxiety, psychosis, or renal insufficiency or in clients who use alcohol
- **3.** Side and adverse effects
  - **a.** Hypersensitivity
  - **b.** CNS reactions
  - **c.** Neurotoxicity
  - **d.** Seizures
  - **e.** Heart failure
  - **f.** Headache
  - **g.** Vertigo
  - **h.** Altered level of consciousness
  - **i.** Irritability, nervousness, anxiety
  - **j.** Confusion
  - **k.** Mood changes, depression, thoughts of suicide
- **4.** Interventions
  - **a.** Monitor level of consciousness.
  - **b.** Monitor for changes in mental status and thought processes.
  - **c.** Monitor renal and hepatic function tests.
  - **d.** Monitor serum medication level to avoid the risk of neurotoxicity; the peak concentration, measured 2 hours after dosing, should be 25 to 35 mcg/mL (140 to 195 mcmol/L).
- **5.** Client education
  - **a.** To take the medication after meals to prevent gastrointestinal upset
  - **b.** To report signs of a rash or signs of CNS toxicity
  - **c.** To avoid driving or performing tasks that require alertness until the reaction to the medication has been determined
  - **d.** About the need for monitoring serum medication levels weekly, as prescribed

H. Streptomycin
- **1.** Description
  - **a.** An aminoglycoside antibiotic used with at least one other antitubercular medication
  - **b.** Bactericidal because of receptor-binding action that interferes with protein synthesis in susceptible organisms
- **2.** Contraindications and cautions
  - **a.** Contraindicated in clients with hypersensitivity, myasthenia gravis, parkinsonism, or eighth cranial nerve damage; usually not given to pregnant clients
  - **b.** Used with caution in the older client, in neonates because of renal insufficiency and organ immaturity, and in young infants because the medication may cause CNS depression
  - **c.** The risk of toxicity increases when taken with other aminoglycosides or nephrotoxicity- or ototoxicity-producing medications.
- **3.** Side and adverse effects (Box 52.8)
- **4.** Interventions
  - **a.** Assess for hypersensitivity.
  - **b.** Monitor liver and renal function test results.
  - **c.** Monitor for ototoxic, neurotoxic, and nephrotoxic reactions.
  - **d.** Monitor peak and trough levels of medication as appropriate.
  - **e.** Perform baseline audiometric testing and repeat every 1 to 2 months, because the medication impairs the eighth cranial nerve.
  - **f.** Monitor for visual changes.
  - **g.** Assess hydration status and maintain adequate hydration during therapy.
  - **h.** Monitor intake and output.
  - **i.** Assess urinalysis results.
  - **j.** Monitor for signs of peripheral neuritis.
- **5.** Client education: To notify the PHCP if hearing loss, changes in vision, urinary problems, persistent headache, or dizziness occurs

XVI. Influenza Medications

A. Vaccines (refer to Chapter 19 for additional information on this vaccine)
- **1.** Description
- **2.** Because the strain of influenza virus is different every year, annual vaccination is recommended (usually sometime during September to April); each time a flu vaccine is administered, the nurse should inform the client of any updated information regarding the vaccine.

BOX 52.8 Side and Adverse Effects of Streptomycin

Nephrotoxicity
- Changes in urine output
- Decreased appetite
- Increased thirst
- Nausea, vomiting

Vestibular Toxicity
- Clumsiness
- Dizziness
- Unsteadiness
- Vertigo

Neurotoxicity
- Muscle numbness
- Seizures
- Tingling
- Twitching

Auditory Toxicity (Ototoxicity)
- A full feeling in the ears
- Ringing in the ears
- Loss of hearing that may be permanent

Telegram & Insta: NCLEX_RN_Edu

The trivalent influenza vaccine includes vaccination against H_1N_1 and H_3N_2 strains (influenza A strains) and an influenza B strain. Because the strain of influenza virus is different every year, vaccine components may change. The vaccine is recommended for all individuals unless a contraindication to receiving it exists.

   a. The nasal spray (live) vaccine, if available, is approved only for healthy people ages 2 through 49.
   b. The nasal spray vaccine is not approved for pregnant individuals.
   c. The flu shots (inactivated vaccine), depending on the manufacturer, are approved for children as young as 6 months of age and are safe for pregnant women.
   d. The nasal spray contains a live flu virus that has been weakened to the point that it cannot cause the flu; its advantage is that it may elicit a stronger immune response than the flu shot in children who have never had the flu or a flu vaccine before.
   e. The disadvantage of the nasal spray is that it may not be quite as protective as the flu shot for older people who have had the flu or flu vaccines before.
   f. All individuals should receive an influenza vaccine. High-priority individuals include pregnant individuals; household contacts and caregivers of children younger than 6 months of age; people ages 6 months to 24 years; health care workers and emergency medical personnel; and adults ages 25 to 64 with a chronic medical condition, such as asthma, or a weakened immune system, which increases the risk of flu complications.

3. Contraindications and cautions
   a. Contraindications of the inactivated vaccine include hypersensitivity, active infection, Guillain-Barré syndrome, active febrile illness, and children younger than 6 months.
   b. Contraindications of the live attenuated vaccine include age younger than 2 years or adults 50 years or older; pregnant individuals; children or adolescents on long-term aspirin therapy; and those with severe nasal congestion or long-term conditions such as asthma; diabetes mellitus; anemia or blood disorders; or heart, kidney, or lung disease.

4. Side and adverse effects
   a. Inactivated vaccine: Localized pain and swelling at the injection site, general body aches and pains, malaise, fever
   b. Attenuated vaccine: Runny nose or nasal congestion, cough, headache, sore throat

5. Interventions
   a. The intramuscular route is recommended for the inactivated vaccine; adults and older children should be vaccinated in the deltoid muscle.
   b. Monitor for side and adverse effects of the vaccine.
   c. Monitor for hypersensitivity reactions in clients receiving vaccination for the first time.

6. Client education
   a. About the importance of an annual vaccination
   b. That the inactivated vaccine contains noninfectious, killed viruses and cannot cause influenza
   c. That any respiratory disease unrelated to influenza can occur after the vaccination
   d. That if the attenuated vaccine is received, the virus may be shed in secretions up to 2 days after vaccination
   e. That development of antibodies in adults takes approximately 2 weeks

8. Visit the Centers for Disease Control and Prevention for updates.

B. Antiviral medications (Table 52.1)

1. Description
   a. Use during outbreaks of influenza depends on the current strain of influenza.
   b. Diagnosis of influenza should include rapid diagnostic tests, because infection from other pathogens may cause symptoms similar to those of influenza infection.

TABLE 52.1 Side and Adverse Effects of Antiviral Influenza Medications

Antiviral Medication	Side and Adverse Effects
Amantadine	Drowsiness, anxiety, psychosis, depression, hallucinations, tremors, confusion, insomnia, orthostatic hypotension, heart failure, blurred vision, constipation, dry mouth, urinary frequency and retention, leukopenia, photosensitivity, dermatitis
Oseltamivir	Insomnia, diarrhea, abdominal pain, cough
Rimantadine	Depression, hallucinations, tremors, seizures, insomnia, poor concentration, asthenia, gait abnormalities, anxiety, confusion, pallor, palpitations, hypotension, edema, tinnitus, eye pain, constipation, dry mouth, anorexia, abdominal pain, diarrhea, dyspepsia, rash
Zanamivir	Ear, nose, and throat infections; diarrhea; nasal symptoms; cough; sinusitis; bronchitis
Peramivir	Diarrhea, constipation, insomnia, high blood pressure

Telegram & Insta: NCLEX_RN_Edu

   c. May also be administered as prophylaxis against infection but should not replace vaccination
2. Contraindicated in hypersensitive clients
3. Side and adverse effects (see Table 52.1)
4. Interventions
   a. Administer within 2 days of onset of symptoms and continue for the entire prescription.
   b. Monitor for side and adverse effects of specific medications.
5. Client education
   a. That the medication may not prevent the transmission of influenza to others
   b. About the need to adjust activities if dizziness or fatigue occurs
   c. About management of side and adverse effects of various medications
   d. To take medication exactly as prescribed and for the duration of prescription

XVII. Pneumococcal Conjugate Vaccine and Pneumococcal Polysaccharide Vaccine (refer to Chapter 19 for additional information on these vaccines)

XVIII. COVID-19 (Coronavirus)

A. Research is consistently being conducted to identify the best treatment for COVID-19.

B. There are vaccines available for COVID-19, and eligible individuals are highly encouraged to receive these available vaccines and recommended boosters.

C. It is critically important to keep updated on the latest approved medications and treatment measures for COVID-19.

D. Refer to the National Institutes of Health (NIH) COVID-19 Treatment Guidelines for the latest approved information. It is important to visit this site frequently to stay updated. See https://www.covid19treatmentguidelines.nih.gov/management/clinical-management/hospitalized-adults--therapeutic-management/

PRACTICE QUESTIONS

1. A client has a prescription to take guaifenesin. The nurse determines that the client understands the proper administration of this medication if the client states that they will perform which action?
   1. Take an extra dose if fever develops
   2. Take the medication with meals only
   3. Increase water intake when taking the medication
   4. Decrease the amount of daily fluid intake

2. The nurse is preparing to administer a dose of naloxone intravenously to a client with an opioid overdose. Which supportive medical equipment would the nurse plan to have at the client's bedside?
   1. Nasogastric tube
   2. Paracentesis tray
   3. Resuscitation equipment
   4. Central line insertion tray

3. A cromolyn sodium inhaler is prescribed for a client with allergic asthma. The nurse provides instructions regarding the adverse effects of this medication and would tell the client that which undesirable effect is associated with this medication?
   1. Insomnia
   2. Constipation
   3. Hypotension
   4. Bronchospasm

4. Terbutaline is prescribed for a client with bronchitis. Which disorder in the client's medical history requires caution by the nurse?
   1. Osteoarthritis
   2. Hypothyroidism
   3. Diabetes mellitus
   4. Polycystic disease

5. Zafirlukast is prescribed for a client with bronchial asthma. Which laboratory test does the nurse expect to be prescribed before the administration of this medication?
   1. Platelet count
   2. Neutrophil count
   3. Liver function tests
   4. Complete blood count

6. A client has been taking isoniazid for 2 months. The client complains to the nurse about numbness, paresthesias, and tingling in the extremities. The nurse interprets that the client is experiencing which problem?
   1. Hypercalcemia
   2. Peripheral neuritis
   3. Small blood vessel spasm
   4. Impaired peripheral circulation

7. A client is to begin a 6-month course of therapy with isoniazid. The nurse would plan to teach the client to take which action?
   1. Use alcohol in small amounts only.
   2. Report yellow eyes or skin immediately.
   3. Increase intake of Swiss or aged cheeses.
   4. Avoid vitamin supplements during therapy.

Telegram & Insta: NCLEX_RN_Edu

8. A client has been started on long-term therapy with rifampin. The nurse would provide which information to the client about the medication?
1. Would always be taken with food or antacids
2. Would be double-dosed if one dose is forgotten
3. Causes orange discoloration of sweat, tears, urine, and feces
4. May be discontinued independently if symptoms are gone in 3 months

9. The nurse has given a client taking ethambutol information about the medication. The nurse determines that the client understands the instructions if the client states that they will **immediately** report which finding?
1. Impaired sense of hearing
2. Gastrointestinal side effects
3. Orange-red discoloration of body secretions
4. Difficulty in discriminating the color red from green

10. A client with tuberculosis is starting antituberculosis therapy with isoniazid. Before giving the client the first dose, the nurse would ensure that which baseline study has been completed?
1. Electrolyte levels
2. Coagulation times
3. Liver enzyme levels
4. Serum creatinine level

11. The nurse has a prescription to give a client salmeterol, 2 puffs, and beclomethasone dipropionate, 2 puffs, by metered-dose inhaler. The nurse would administer the medication using which procedure?
1. Beclomethasone first and then the salmeterol
2. Salmeterol first and then the beclomethasone
3. Alternating a single puff of each, beginning with the salmeterol
4. Alternating a single puff of each, beginning with the beclomethasone

12. Rifabutin is prescribed for a client with active Mycobacterium avium complex (MAC) disease and tuberculosis. The nurse would monitor for which side and adverse effects of rifabutin? **Select all that apply.**
- ❑ 1. Signs of hepatitis
- ❑ 2. Flulike syndrome
- ❑ 3. Low neutrophil count
- ❑ 4. Vitamin B_6 deficiency
- ❑ 5. Ocular pain or blurred vision
- ❑ 6. Tingling and numbness of the fingers

13. A client begins therapy with theophylline. The nurse plans to teach the client to limit the intake of which items while taking this medication?
1. Coffee, cola, and chocolate
2. Oysters, lobster, and shrimp
3. Melons, oranges, and pineapple
4. Cottage cheese, cream cheese, and dairy creamers

14. The nurse has just administered the first dose of omalizumab to a client with asthma. Which statement by the client alerts the nurse of a life-threatening effect?
1. "I have a severe headache."
2. "My feet are quite swollen."
3. "I am nauseated and may vomit."
4. "My lips and tongue are swollen."

15. The nurse is teaching a client who is beginning antiviral therapy for influenza. Which statement by the client indicates an understanding of the instructions?
1. "I must take the medication exactly as prescribed."
2. "Once I start the medication, I will no longer be contagious."
3. "I will not get any colds or infections while taking this medication."
4. "This medication has minimal side effects, and I can return to normal activities."

16. The nurse is caring for a client receiving an albuterol/ipratropium nebulized breathing treatment. Which report from the client would the nurse note as an expected side effect of this combination medication?
1. "I feel as though my heart is racing."
2. "I feel more bloated than usual."
3. "My eyes have been watering lately."
4. "I haven't had a bowel movement in 4 days."

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 3
Rationale: Guaifenesin is an expectorant and needs to be taken with a full glass of water to decrease the viscosity of secretions. Extra doses would not be taken. The client would contact the primary health care provider if the cough lasts longer than 1 week or is accompanied by fever, rash, sore throat, or persistent headache. Fluids are needed to decrease the viscosity of secretions. The medication does not have to be taken with meals.
Test-Taking Strategy: Begin to answer this question by eliminating option 1 first, recalling that *extra doses* of medication would not be taken. Next, eliminate option 2 because of the **closed-ended word** "only." Next, knowing that increased fluid helps liquefy secretions for more effective coughing directs you to the correct option.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 564.

2. *Answer:* 3
Rationale: The nurse administering naloxone for suspected opioid overdose needs to have resuscitation equipment readily available to support naloxone therapy if it is needed. Other adjuncts that may be needed include oxygen, a mechanical ventilator, and vasopressors.
Test-Taking Strategy: Focus on the **subject,** supportive medical equipment. Note the words *opioid overdose.* Recalling the effects of these types of medications will direct you to the correct option. The correct option is also the **umbrella option.**
Reference: Gahart, B., Nazareno, A., & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. pp. 954-955.

3. *Answer:* 4
Rationale: Cromolyn sodium is an inhaled nonsteroidal antiallergy agent and a mast cell stabilizer. Undesirable effects associated with inhalation therapy of cromolyn sodium are bronchospasm, cough, nasal congestion, throat irritation, and wheezing. Clients receiving this medication orally may experience pruritus, nausea, diarrhea, and myalgia.
Test-Taking Strategy: Note the words *undesirable effect.* This will assist in directing you to the correct option. In addition, use the **ABCs—airway, breathing, and circulation**—to select the correct option. The correct option addresses the airway.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. p. 933.

4. *Answer:* 3
Rationale: Terbutaline is a bronchodilator and is contraindicated in clients with hypersensitivity to sympathomimetics. It is used with caution in clients with impaired cardiac function, diabetes mellitus, hypertension, hyperthyroidism, or a history of seizures. The medication may increase blood glucose levels.
Test-Taking Strategy: Focus on the **subject,** cautions for using terbutaline. Specific knowledge regarding the contraindications and cautions associated with the use of this medication is needed to answer this question. Remember that terbutaline is used with caution in the client with diabetes mellitus.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 779, 781.

5. *Answer:* 3
Rationale: Zafirlukast is a leukotriene receptor antagonist used in the prophylaxis and long-term treatment of bronchial asthma. Zafirlukast is used with caution in clients with impaired hepatic function. Liver function laboratory tests need to be performed to obtain a baseline, and the levels need to be monitored during administration of the medication. It is not necessary to perform the other laboratory tests before administration of the medication.
Test-Taking Strategy: Eliminate options 2 and 4 first because they are **comparable or alike,** noting that a complete blood count would include a neutrophil count. From the remaining options, you would need to know that this medication affects hepatic function.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 1322.

6. *Answer:* 2
Rationale: Isoniazid is an antitubercular medication. A common side effect of isoniazid is peripheral neuritis, manifested by numbness, tingling, and paresthesias in the extremities. This can be minimized with pyridoxine (vitamin B_6) intake. Options 1, 3, and 4 are not associated with the information in the question.
Test-Taking Strategy: Focus on the **data in the question,** numbness, paresthesias, and tingling in the extremities. Options 3 and 4 would not cause the symptoms presented in the question but instead would cause pallor and coolness. From the remaining options, you need to know that peripheral neuritis is an adverse effect of isoniazid, and that these signs and symptoms do not correlate with hypercalcemia.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 1088-1089, 1095.

7. *Answer:* 2
Rationale: Isoniazid is hepatotoxic; therefore, the client is taught to immediately report signs and symptoms of hepatitis, which include yellow skin and sclera. For the same reason, alcohol needs to be avoided during therapy. The client needs to avoid intake of Swiss cheese, fish such as tuna, and foods containing tyramine because they may cause a reaction characterized by redness and itching of the skin, flushing, sweating, tachycardia, headache, or light-headedness. The client can avoid developing peripheral neuritis by increasing the intake of pyridoxine (vitamin B_6) during the course of isoniazid therapy.
Test-Taking Strategy: Focus on the **subject,** client teaching for isoniazid. Because alcohol intake is prohibited with the use of many medications, eliminate option 1 first. Because the client receiving this medication typically is given supplements of vitamin B_6, option 4 is incorrect and is eliminated next. Recalling that the medication is hepatotoxic will direct you to the correct option.

Telegram & Insta: NCLEX_RN_Edu

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 1089, 1095.

8. *Answer:* 3

Rationale: Rifampin causes orange-red discoloration of body secretions and will stain soft contact lenses permanently. Rifampin needs to be taken exactly as directed. Doses would not be doubled or skipped. The client would not stop therapy until directed to do so by a primary health care provider. It is best to administer the medication on an empty stomach unless it causes gastrointestinal upset; then it may be taken with food. Antacids, if prescribed, need to be taken at least 1 hour before the medication.

Test-Taking Strategy: Options 2 and 4 are **comparable or alike** and are inaccurate, based on general guidelines for medication administration; the client would not double-dose or discontinue medication independently. Eliminate option 1 next because of the **closed-ended word** "always."

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 652.

9. *Answer:* 4

Rationale: Ethambutol causes optic neuritis, which decreases visual acuity and the ability to discriminate between the colors red and green. This poses a potential safety hazard when a client is driving a motor vehicle. The client is taught to report this symptom immediately. The client also is taught to take the medication with food if gastrointestinal upset occurs. Impaired hearing results from antitubercular therapy with streptomycin. Orange-red discoloration of secretions occurs with rifampin.

Test-Taking Strategy: Note the **strategic word,** *immediately.* Option 2 is the least likely symptom to report; instead, it would be managed by taking the medication with food. To select among the other options, you must know that this medication causes optic neuritis, resulting in difficulty with red-green discrimination.

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 1091, 1096.

10. *Answer:* 3

Rationale: Isoniazid therapy can cause an elevation of hepatic enzyme levels and hepatitis. Therefore, liver enzyme levels are monitored when therapy is initiated and during the first 3 months of therapy. They may be monitored longer in the client who is older than 50 years or who abuses alcohol. The laboratory tests in options 1, 2, and 4 are not necessary.

Test-Taking Strategy: Focus on the **subject,** the laboratory value to monitor. Recalling that this medication can be toxic to the liver will direct you to the correct option.

Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022.* St. Louis: Elsevier. pp. 638-639.

11. *Answer:* 2

Rationale: Salmeterol is an adrenergic type of bronchodilator, and beclomethasone dipropionate is a glucocorticoid. Bronchodilators are always administered before glucocorticoids when both are to be given on the same time schedule. This allows for widening of the air passages by the bronchodilator, which then makes the glucocorticoid more effective.

Test-Taking Strategy: Focus on the **subject,** the procedure for administering inhaled medications. To answer this question correctly, you must know two different things. First, you must know that a bronchodilator is always given before a glucocorticoid. This would allow you to eliminate options 3 and 4, because you would not alternate the medications. To select between the remaining option and the correct option, you must know that salmeterol is a bronchodilator, whereas beclomethasone is a glucocorticoid.

Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 1129-1130.

12. *Answer:* 1, 2, 3, 5

Rationale: Rifabutin may be prescribed for a client with active MAC disease and tuberculosis. It inhibits mycobacterial DNA-dependent RNA polymerase and suppresses protein synthesis. Side and adverse effects include rash, gastrointestinal disturbances, neutropenia (low neutrophil count), red-orange–colored body secretions, uveitis (blurred vision and eye pain), myositis, arthralgia, hepatitis, chest pain with dyspnea, and flulike syndrome. Vitamin B_6 deficiency and numbness and tingling in the extremities are associated with the use of isoniazid.

Test-Taking Strategy: Focus on the **subject,** side and adverse effects of rifabutin. Specific knowledge is needed to answer correctly. Remember that hepatitis, flulike syndrome, neutropenia, and uveitis can occur.

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 1090-1091.

13. *Answer:* 1

Rationale: Theophylline is a methylxanthine bronchodilator. The nurse teaches the client to limit the intake of xanthine-containing foods while taking this medication. These foods include coffee, cola, and chocolate.

Test-Taking Strategy: Focus on the **subject,** food items that need to be limited. Recall that theophylline is a xanthine bronchodilator and that intake of excessive amounts of foods naturally high in xanthines needs to be limited. Also, recalling that these medications cause cardiac and central nervous system stimulation will direct you to the correct option.

Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 573, 581.

14. *Answer:* 4

Rationale: Omalizumab is an antiinflammatory and monoclonal antibody used for long-term control of asthma. Anaphylactic reactions can occur with the administration of omalizumab. The nurse administering the medication would monitor for adverse reactions of the medication. Swelling of the lips and tongue are an indication of an anaphylaxis. The client statements in options 1, 2, and 3 are not indicative of an adverse reaction.

Test-Taking Strategy: Focus on the **subject,** a life-threatening effect. Recall that anaphylactic reactions can occur with the

Telegram & Insta: NCLEX_RN_Edu

administration of omalizumab. Knowing the signs of a reaction will direct you to the correct option.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 933, 953.

15. *Answer:* 1
Rationale: Antiviral medications for influenza must be taken exactly as prescribed. These medications do not prevent the spread of influenza, and clients are usually contagious for up to 2 days after the initiation of antiviral medications. Secondary bacterial infections may occur despite antiviral treatment. Side effects occur with these medications and may necessitate a change in activities, especially when driving or operating machinery if dizziness occurs.
Test-Taking Strategy: Focus on the **subject,** client instructions for antiviral therapy, and note the words *indicates an understanding.* Using general medication guidelines will direct you to the correct option.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 641-642.

16. *Answer:* 1
Rationale: Albuterol/ipratropium is a combination agent—one is a β_2-adrenergic agonist and the other is an anticholinergic medication. In combination they produce an overall bronchodilation effect. Common side and adverse effects include headache, dizziness, dry mouth, tremors, nervousness, and tachycardia. Therefore, option 1 is correct. Options 2, 3, and 4 are not specifically associated with this medication.
Test-Taking Strategy: Begin to answer this question by eliminating options 2 and 4 first, noting they are **comparable or alike.** Next, eliminate option 3 because this medication causes anticholinergic effects such as dry eyes and dry mouth.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 570, 572.

UNIT XII

Cardiovascular Problems of the Adult Client

Pyramid to Success

Pyramid Points focus on assessment data related to cardiovascular risks, health screening and promotion, complications of the various cardiovascular problems, emergency measures, and client education. Assessment findings and treatment in coronary artery disease, myocardial infarction, heart failure and pulmonary edema, pericarditis, aneurysms, hypertension, and arterial and venous problems are emphasized. You need to be able to identify the most common dysrhythmias and determine the appropriate interventions for these dysrhythmias, including the use of a pacemaker. Care of the client following diagnostic treatments and surgical procedures is important. Note appropriate and therapeutic client positions, particularly with arterial and venous problems of the extremities. Focus on treatments and medications prescribed for the various cardiovascular problems and client teaching related to prescribed treatment plans. Be familiar with the components related to cardiac rehabilitation.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Consulting with the interprofessional health care team
Maintaining asepsis
Maintaining standard and other precautions
Prioritizing hypotheses based on the client's needs
Recognizing cues that indicate the need for consultations and referrals
Upholding client rights
Verifying that informed consent related to treatments and procedures has been obtained

Health Promotion and Maintenance

Discussing alterations in lifestyle
Generating solutions with the client for integrating necessary lifestyle alterations
Mobilizing appropriate community resources
Performing cardiovascular assessment techniques
Preventing cardiovascular disease
Promoting cardiac rehabilitation
Providing health screening and health promotion programs
Teaching related to diet therapy, exercise, and medications

Psychosocial Integrity

Assisting the client to accept lifestyle changes
Considering religious, spiritual, and cultural influences on health
Discussing grief and loss and end-of-life issues
Discussing situational role changes
Discussing unexpected body image changes
Identifying coping mechanisms
Identifying fear, anxiety, and denial
Identifying support systems

Physiological Integrity

Administering medications
Analyzing cues that indicate a cardiovascular complication
Differentiating between characteristics of angina and myocardial infarction
Discussing activity limitations and promoting rest and sleep
Evaluating for therapeutic effects of medications and other treatments
Identifying dysrhythmias and taking action to treat them
Monitoring cardiac enzyme and troponin levels and other cardiovascular-related laboratory values
Monitoring for complications related to cardiovascular problems
Monitoring hemodynamics
Providing nonpharmacological and pharmacological comfort interventions
Taking action and responding to medical emergencies

PRIORITY CONCEPTS Health Promotion; Perfusion

I. Anatomy and Physiology

A. Heart and heart wall layers
- **1.** The heart is located in the mediastinum.
- **2.** The heart consists of three layers.
  - **a.** The epicardium is the outermost layer of the heart.
  - **b.** The myocardium is the middle layer and is the actual contracting muscle of the heart.
  - **c.** The endocardium is the innermost layer and lines the inner chambers and heart valves.

B. Pericardial sac
- **1.** Encases and protects the heart from trauma and infection
- **2.** Has two layers
  - **a.** The parietal pericardium is the tough, fibrous outer membrane that attaches anteriorly to the lower half of the sternum, posteriorly to the thoracic vertebrae, and inferiorly to the diaphragm.
  - **b.** The visceral pericardium is the thin, inner layer that closely adheres to the heart.
- **3.** The pericardial space between the parietal and visceral layers holds 5 to 20 mL of pericardial fluid to lubricate the pericardial surfaces and cushion the heart.

C. There are four heart chambers.
- **1.** The right atrium receives deoxygenated blood from the body via the superior and inferior vena cava.
- **2.** The right ventricle receives blood from the right atrium and pumps it to the lungs via the pulmonary artery.
- **3.** The left atrium receives oxygenated blood from the lungs via four pulmonary veins.
- **4.** The left ventricle is the largest and most muscular chamber; it receives oxygenated blood from the lungs via the left atrium and pumps blood into the systemic circulation via the aorta.

D. There are four valves in the heart.
- **1.** There are two atrioventricular valves, the tricuspid and the mitral, which lie between the atria and ventricles.
  - **a.** The tricuspid valve is located on the right side of the heart.
  - **b.** The bicuspid (mitral) valve is located on the left side of the heart.
  - **c.** The atrioventricular valves close at the beginning of ventricular contraction and prevent blood from flowing back into the atria from the ventricles; these valves open when the ventricles relax.
- **2.** There are two semilunar valves, the pulmonic and the aortic.
  - **a.** The pulmonic semilunar valve lies between the right ventricle and the pulmonary artery.
  - **b.** The aortic semilunar valve lies between the left ventricle and the aorta.
  - **c.** The semilunar valves prevent blood from flowing back into the ventricles during relaxation; they open during ventricular contraction and close when the ventricles begin to relax.

E. Sinoatrial (SA) node
- **1.** The main pacemaker that initiates each heartbeat
- **2.** It is located at the junction of the superior vena cava and the right atrium.
- **3.** The SA node generates electrical impulses 60 to 100 times per minute and is controlled by the sympathetic and parasympathetic nervous systems.

Telegram & Insta: NCLEX_RN_Edu

F. Atrioventricular (AV) node
1. Located in the lower aspect of the atrial septum
2. Receives electrical impulses from the SA node
3. If the SA node fails, the AV node can initiate and sustain a heart rate of 40 to 60 beats per minute.

G. The bundle of His
1. A continuation of the AV node; located at the interventricular septum
2. It branches into the right bundle branch, which extends down the right side of the interventricular septum; and the left bundle branch, which extends into the left ventricle.
3. The right and left bundle branches terminate in the Purkinje fibers.

H. Purkinje fibers
1. Purkinje fibers are a diffuse network of conducting strands located beneath the ventricular endocardium.
2. These fibers spread the wave of depolarization through the ventricles.
3. Purkinje fibers can act as the pacemaker with a rate between 20 and 40 beats per minute if the SA and AV nodes fail.

I. Coronary arteries (Fig. 53.1)
1. The right main coronary artery supplies the right atrium and ventricle, the inferior portion of the left ventricle, the posterior septal wall, and the SA and AV nodes.
2. The left main coronary artery consists of two major branches, the left anterior descending (LAD) and the circumflex arteries.
3. The LAD artery supplies blood to the anterior wall of the left ventricle, the anterior ventricular septum, and the apex of the left ventricle.
4. The circumflex artery supplies blood to the left atrium and the lateral and posterior surfaces of the left ventricle.

The coronary arteries supply the capillaries of the myocardium with blood. If blockage occurs in these arteries, the client is at risk for myocardial infarction (MI).

J. Heart sounds
1. The first heart sound (S_1) is heard as the atrioventricular valves close and is loudest at the apex of the heart.
2. The second heart sound (S_2) is heard when the semilunar valves close and is loudest at the base of the heart.
3. A third heart sound (S_3) may be heard if ventricular wall compliance is decreased and structures in the ventricular wall vibrate; this can occur in conditions such as heart failure or valvular regurgitation. However, a third heart sound may be normal in individuals younger than 30 years.

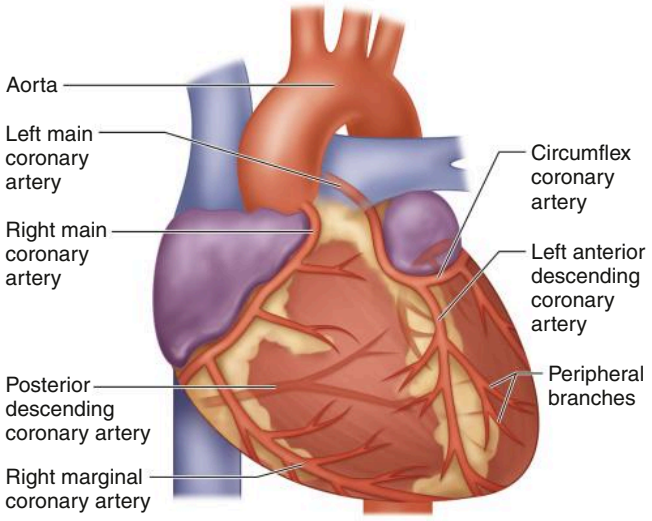

FIG. 53.1 Coronary arterial system.

4. A fourth heart sound (S_4) may be heard on atrial systole if resistance to ventricular filling is present. Causes of this abnormal finding include cardiac hypertrophy, disease, or injury to the ventricular wall.

K. Heart rate
1. The faster the heart rate, the less time the heart has for filling. At very fast rates the cardiac output decreases.
2. The normal sinus heart rate is 60 to 100 beats per minute.
3. Sinus tachycardia is a rate more than 100 beats per minute.
4. Sinus bradycardia is a rate less than 60 beats per minute.

L. Autonomic nervous system
1. Stimulation of sympathetic nerve fibers releases the neurotransmitter norepinephrine, producing an increased heart rate, increased conduction speed through the AV node, increased atrial and ventricular contractility, and peripheral vasoconstriction. Stimulation occurs when a decrease in pressure is detected.
2. Stimulation of the parasympathetic nerve fibers releases the neurotransmitter acetylcholine, which decreases the heart rate and lessens atrial and ventricular contractility and conductivity. Stimulation occurs when an increase in pressure is detected.

M. Blood pressure (BP) control
1. Baroreceptors (specialized nerve endings affected by changes in the arterial BP), also called *pressoreceptors*, are located in the walls of the aortic arch and carotid sinuses.
2. Increases in arterial pressure stimulate baroreceptors, and the heart rate and arterial pressure decrease.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Decreases in arterial pressure reduce stimulation of the baroreceptors and vasoconstriction occurs, as does an increase in heart rate.
4. Stretch receptors, located in the vena cava and the right atrium, respond to pressure changes that affect circulatory blood volume.
5. When the BP decreases as a result of hypovolemia, a sympathetic response occurs, causing an increased heart rate and blood vessel constriction; when the BP increases as a result of hypervolemia, an opposite effect occurs.
6. Antidiuretic hormone (vasopressin) influences BP indirectly by regulating vascular volume.
7. Increases in blood volume result in decreased antidiuretic hormone release, increasing diuresis, decreasing blood volume, and thus decreasing BP.
8. Decreases in blood volume result in increased antidiuretic hormone release; this promotes an increase in blood volume and therefore BP.
9. Renin, a potent vasoconstrictor, causes the BP to increase.
10. Renin converts angiotensinogen to angiotensin I; angiotensin I is then converted to angiotensin II in the lungs.
11. Angiotensin II stimulates the release of aldosterone, which promotes water and sodium retention by the kidneys; this action increases blood volume and BP.

N. The vascular system

1. Arteries are vessels through which the blood passes away from the heart to various parts of the body; they convey highly oxygenated blood from the left side of heart to the tissues.
2. Arterioles control the blood flow into the capillaries.
3. Capillaries allow the exchange of fluid and nutrients between the blood and the interstitial spaces.
4. Venules receive blood from the capillary bed and move blood into the veins.
5. Veins transport deoxygenated blood from the tissues back to the right heart and then to the lungs for oxygenation.
6. Valves help return blood to the heart against the force of gravity.
7. The lymphatics drain the tissues and return the tissue fluid to the blood.

II. Diagnostic Tests and Procedures (refer to Chapter 10 for further information on laboratory reference levels)

A. Cardiac markers

1. Troponin
   a. Troponin is composed of three proteins—troponin C, cardiac troponin I, and cardiac troponin T.
   b. Troponin I has a high affinity for myocardial injury; it rises within 3 hours and persists for up to 7 to 10 days.
   c. Normal values are low, with troponin I being less than 0.35 ng/mL (less than 0.35 mcg/L) and troponin T being less than 0.1 ng/mL (less than 0.1 mcg/L); thus, any rise can indicate myocardial cell damage.
2. High-sensitivity Troponin (hsTnT)
   a. HsTnT assays detect troponins at much lower concentrations and as early as 60 to 90 minutes after myocardial cell injury.
   b. HsTnT speeds the triage of clients with suspected myocardial infarction.
   c. Normal values are low, <14 ng/L for women and <22 ng/L for men.
3. CK-MB (creatine kinase, myocardial muscle)
   a. An elevation in value indicates myocardial damage.
   b. An elevation occurs within hours and peaks at 18 hours after acute ischemia.
   c. Normal value for CK-MB (CK-2) ranges from 2 to 6 ng/mL (2 to 6 mcg/L).
4. Myoglobin
   a. Myoglobin is an oxygen-binding protein found in cardiac and skeletal muscle.
   b. The level rises within 2 hours after cell death, with a rapid decline in the level after 7 hours; however, it is not cardiac specific.

B. Complete blood count

1. The red blood cell count decreases in rheumatic heart disease and infective endocarditis, and increases in conditions characterized by inadequate tissue oxygenation.
2. The white blood cell count increases in infectious and inflammatory diseases of the heart and after MI, because large numbers of white blood cells are needed to dispose of the necrotic tissue resulting from the infarction.
3. An elevated hematocrit level can reflect vascular volume depletion.
4. Decreases in hemoglobin and hematocrit levels can indicate anemia.

C. Blood coagulation factors: An increase in coagulation factors can occur during and after MI, placing the client at greater risk for thrombophlebitis and formation of clots in the coronary arteries.

D. Serum lipids (refer to Chapter 10)

1. The lipid profile measures serum cholesterol, triglyceride, and lipoprotein levels.
2. The lipid profile is used to assess the risk of developing coronary artery disease.
3. Lipoprotein-*a* or *Lp(a)*, a modified form of low-density lipoprotein (LDL), increases atherosclerotic plaques and increases clots.

Telegram & Insta: NCLEX_RN_Edu

E. Homocysteine: Elevated levels may increase the risk of cardiovascular disease; normal value is 4.5 to 11.9 mcmol/L (4.5 to 11.9 mcmol/L), age and gender dependent.

F. Highly sensitive C-reactive protein (hsCRP): Detects an inflammatory process such as that associated with the development of atherothrombosis; a level less than 1 mg/L is considered low risk, and a level greater than 3 mg/L places the client at high risk for heart disease.

G. Microalbuminuria: A small amount of protein in the urine has been a marker for endothelial dysfunction in cardiovascular disease.

H. Electrolytes (refer to Chapters 8 and 10)

1. Potassium

a. Hypokalemia causes increased cardiac electrical instability, ventricular dysrhythmias, and increased risk of digoxin toxicity.

b. In hypokalemia, the electrocardiogram (ECG) shows flattening and inversion of the T wave, the appearance of a U wave, and ST depression.

c. Hyperkalemia causes asystole and ventricular dysrhythmias.

d. In hyperkalemia, the ECG may show tall, peaked T waves, widened QRS complexes, prolonged PR intervals, or flat P waves.

2. Sodium

a. The serum sodium level decreases with the use of diuretics.

b. The serum sodium level decreases in heart failure, indicating water excess.

I. Calcium

1. Hypocalcemia can cause ventricular dysrhythmias, prolonged ST and QT intervals, and cardiac arrest.

2. Hypercalcemia can cause a shortened ST segment and widened T wave, atrioventricular block, tachycardia or bradycardia, digitalis hypersensitivity, and cardiac arrest.

J. Phosphorus level: Phosphorus levels should be interpreted with calcium levels, because the kidneys retain or excrete them in an inverse relationship.

K. Magnesium

1. A low magnesium level can cause ventricular tachycardia and fibrillation.

2. Electrocardiographic changes that may be observed with hypomagnesemia include tall T waves and depressed ST segments.

3. A high magnesium level can cause muscle weakness, hypotension, and bradycardia.

4. Electrocardiographic changes that may be observed with hypermagnesemia include a prolonged PR interval and widened QRS complex.

Electrolyte and mineral imbalances can cause cardiac electrical instability that can result in life-threatening dysrhythmias.

L. Blood urea nitrogen: The blood urea nitrogen level is elevated in heart disorders such as heart failure and cardiogenic shock that reduce renal circulation.

M. Blood glucose: An acute cardiac episode can elevate the blood glucose level.

N. B-type natriuretic peptide (BNP)

1. BNP is released in response to atrial and ventricular stretch; it serves as a marker for heart failure.

2. BNP levels should be less than 100 ng/mL (less than 100 mcg/L); the higher the level, the more severe the heart failure.

O. Chest x-ray

1. Description: Radiography of the chest is done to determine anatomical changes such as the size, silhouette, and position of the heart.

2. Interventions

a. Prepare the client, explaining the purpose and procedure.

b. Remove jewelry.

c. Ensure that the client is not pregnant.

P. Electrocardiography (Box 53.1)

1. Description: This common noninvasive diagnostic test records the electrical activity of the heart and is useful for detecting cardiac dysrhythmias, the location and extent of MI, and cardiac hypertrophy, and for evaluation of the effectiveness of cardiac medications.

2. Interventions

a. Determine the client's ability to lie still; advise the client to lie still, breathe normally, and refrain from talking during the test.

b. Reassure the client that an electrical shock will not occur.

c. Document any cardiac medications the client is taking.

Q. Holter monitoring

1. Description

a. A noninvasive test; the client wears a monitor and an electrocardiographic tracing is recorded continuously over a period of 24 hours or more while the client performs activities of daily living.

b. The monitor identifies dysrhythmias if they occur and evaluates the effectiveness of antidysrhythmics or pacemaker therapy.

2. Interventions

a. Instruct the client to resume normal daily activities and to maintain a diary documenting activities if asked to do so and any symptoms that may develop for correlation with the electrocardiographic tracing.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 53.1 Basics of Electrocardiography

- An electrocardiogram (ECG) reflects the electrical activity of cardiac cells and records electrical activity at a speed of 25 mm/second.
- An electrocardiographic strip consists of horizontal lines representing seconds and vertical lines representing voltage.
- Each small square represents 0.04 second.
- Each large square represents 0.20 second.
- The P wave represents atrial depolarization.
- The PR interval represents the time it takes an impulse to travel from the atria through the atrioventricular node, bundle of His, and bundle branches to the Purkinje fibers.
- Normal PR interval duration ranges from 0.12 to 0.2 second.
- The PR interval is measured from the beginning of the P wave to the end of the PR segment.
- The QRS complex represents ventricular depolarization.
- Normal QRS complex duration ranges from 0.04 to 0.1 second.
- The Q wave appears as the first negative deflection in the QRS complex and reflects initial ventricular septal depolarization.
- The R wave is the first positive deflection in the QRS complex.
- The S wave appears as the second negative deflection in the QRS complex.
- The J point marks the end of the QRS complex and the beginning of the ST segment.
- The QRS duration is measured from the end of the PR segment to the J point.
- The ST segment represents early ventricular repolarization.
- The T wave represents ventricular repolarization and ventricular diastole.
- The U wave may follow the T wave.
- A prominent U wave may indicate an electrolyte abnormality, such as hypokalemia.
- The QT interval represents ventricular refractory time or the total time required for ventricular depolarization and repolarization.
- The QT interval is measured from the beginning of the QRS complex to the end of the T wave.
- The QT interval normally lasts 0.32 to 0.4 second but varies with the client's heart rate, age, and gender.

b. Instruct the client using a wired monitor to avoid tub baths, showers, or swimming, because they will interfere with the electrocardiographic recorder device.

R. Echocardiography

1. Description

a. This noninvasive procedure is based on the principles of ultrasound and evaluates structural and functional changes in the heart.

b. Used to detect valvular abnormalities, congenital heart defects, wall motion, ejection fraction, and cardiac function.

c. Transesophageal echocardiography may be performed, in which the echocardiogram is done through the esophagus to view the posterior structures of the heart; this is an invasive exam and requires preparation and care similar to endoscopy procedures.

2. Interventions: Advise the client to lie still, breathe normally, and refrain from talking during the test.

S. Exercise electrocardiography testing (stress test)

1. Description

a. This noninvasive test studies the heart during activity to detect and evaluate coronary artery disease.

b. Treadmill testing is the most commonly used mode of stress testing.

c. If the client is unable to tolerate exercise, an intravenous (IV) infusion of dipyridamole or dobutamine hydrochloride is given to dilate the coronary arteries and simulate the effect of exercise; the client may need to be NPO (nothing by mouth) for 3 to 6 hours preprocedure.

2. Preprocedure interventions

a. Ensure that an informed consent is obtained if required.

b. Encourage adequate rest the night before the procedure.

c. Instruct the client having a noninvasive test to eat a light meal 1 to 2 hours before the procedure.

d. Instruct the client to avoid smoking, alcohol, and caffeine before the procedure.

e. Instruct the client to ask the primary health care provider (PHCP) or cardiologist about taking prescribed medication on the day of the procedure; theophylline products are usually withheld 12 hours before the test, and calcium channel blockers and beta blockers are usually withheld on the day of the test to allow the heart rate to increase during the stress portion of the test.

f. Instruct the client to wear nonconstrictive, comfortable clothing and supportive rubber-soled shoes for the exercise stress test.

g. Instruct the client to notify the PHCP if any chest pain, dizziness, or shortness of breath occurs during the procedure.

3. Postprocedure interventions: Instruct the client to avoid taking a hot bath or shower for at least 1 to 2 hours.

T. Myocardial nuclear perfusion imaging (MNPI)

1. Description

a. Nuclear cardiology involves the use of radionuclide techniques and scanning for cardiovascular assessment.

Telegram & Insta: NCLEX_RN_Edu

b. The most common tests include technetium pyrophosphate scanning, thallium imaging, and multigated cardiac blood pool imaging; these tests can evaluate cardiac motion and calculate the ejection fraction.

2. Preprocedure interventions

a. Ensure that an informed consent is obtained.

b. Inform the client that a small amount of radioisotope will be injected and that the radiation exposure and risks are minimal.

3. Postprocedure interventions

a. Assess vital signs.

b. Assess injection site for bleeding or discomfort.

c. Inform the client that fatigue is possible.

U. Magnetic resonance imaging (MRI)

1. Description

a. This is a noninvasive diagnostic test that produces an image of the heart or great vessels through the interaction of magnetic fields, radio waves, and atomic nuclei.

b. It provides information on chamber size and thickness, valve and ventricular function, and blood flow through the great vessels and coronary arteries.

2. Preprocedure interventions

a. Evaluate the client for the presence of a pacemaker or other implanted items that present a contraindication to the test.

b. Ensure that the client has removed all metallic objects such as a watch, jewelry, clothing with metal fasteners, and metal hair fasteners.

c. Inform the client they may experience claustrophobia while in the scanner.

V. Electrophysiological studies: An invasive procedure in which a programmed electrical stimulation of the heart is induced to cause dysrhythmias and conduction defects; assists in finding an accurate diagnosis and aids in determining treatment

W. Electron-beam computed tomography (EBCT) scan: Determines whether calcifications are present in the arteries; a coronary artery calcium (CAC) score is provided (a score higher than 300 indicates high risk of myocardial infarction and requires intensive preventive treatment).

X. Cardiac catheterization (Fig. 53.2)

1. Description

a. An invasive test involving insertion of a catheter into the heart and surrounding vessels

b. Obtains information about the structure and performance of the heart chambers and valves and the coronary circulation

2. Preprocedure interventions

a. Ensure that informed consent has been obtained.

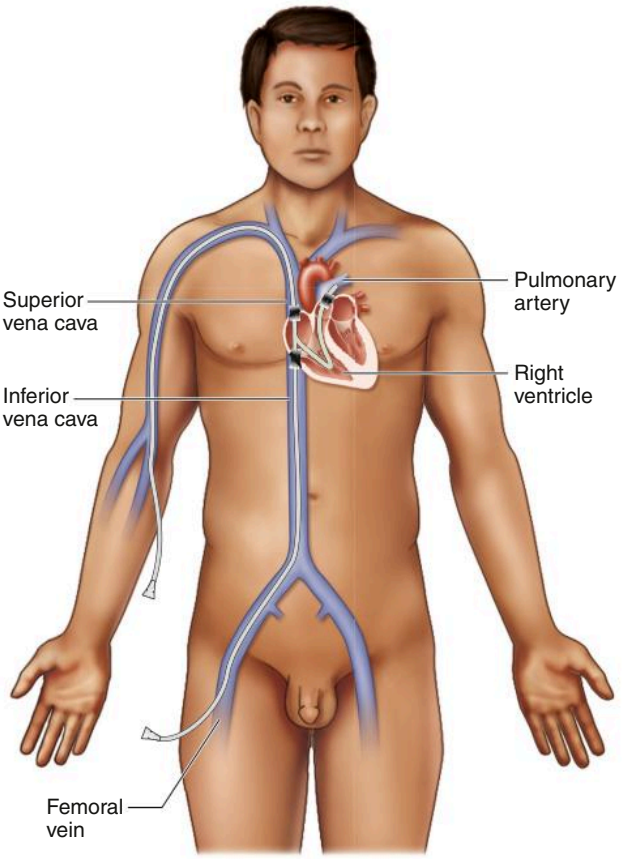

FIG. 53.2 Right-sided heart catheterization. The catheter is inserted into the femoral vein and advanced into the inferior vena cava (or, if into an antecubital or basilic vein, through the superior vena cava), right atrium, right ventricle, and pulmonary artery.

b. Assess for allergies to seafood, iodine, or radiopaque dyes; if allergic, the client may be premedicated with antihistamines and corticosteroids to prevent a reaction.

c. Withhold solid food for 6 to 8 hours and liquids for 4 hours as prescribed to prevent vomiting and aspiration during the procedure.

d. Document the client's height and weight, because these data will be needed to determine the amount of dye to be administered.

e. Document baseline vital signs and note the quality and presence of peripheral pulses for postprocedure comparison.

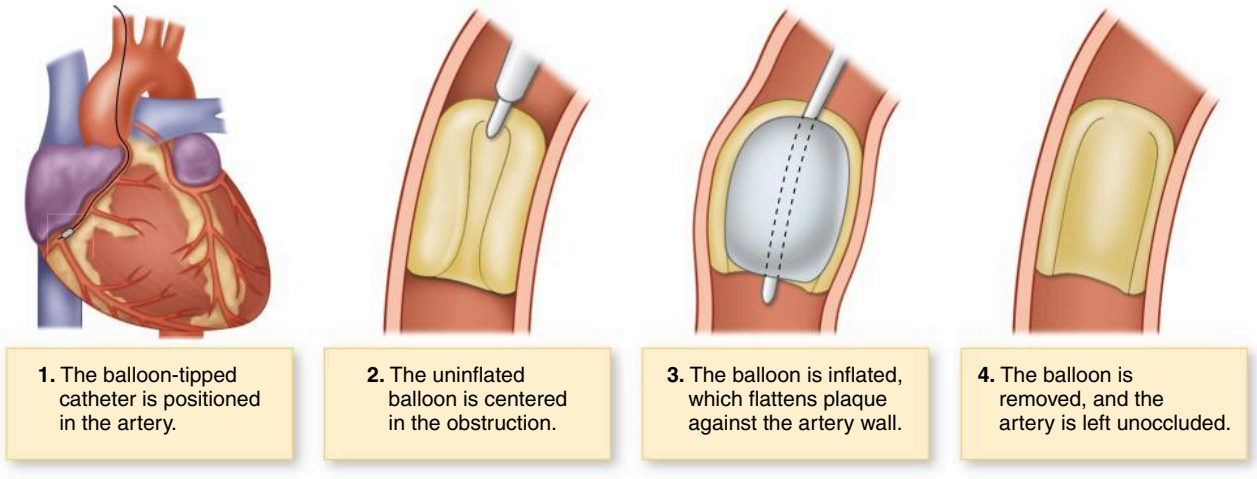
f. Inform the client that a local anesthetic will be administered before catheter insertion.

g. Inform the client that they may feel a fluttery feeling as the catheter passes through the heart, a flushed and warm feeling when the dye is injected, a desire to cough, and palpitations caused by heart irritability.

h. The insertion site is prepared by shaving or clipping the hair and cleaning with an antiseptic solution.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu



1. The balloon-tipped catheter is positioned in the artery.
2. The uninflated balloon is centered in the obstruction.
3. The balloon is inflated, which flattens plaque against the artery wall.
4. The balloon is removed, and the artery is left unoccluded.

FIG. 53.3 Percutaneous transluminal coronary angioplasty.

i. Administer preprocedure medications such as sedatives if prescribed.
j. Insert an IV line if prescribed.

If a client taking metformin is scheduled to undergo a procedure requiring the administration of iodine dye, the metformin is withheld for 24 hours prior to the procedure because of the risk of lactic acidosis. The medication is not resumed until prescribed by the PHCP (usually 48 hours after the procedure or after renal function studies are done and the results are evaluated).

3. Postprocedure interventions
a. Monitor vital signs and cardiac rhythm for dysrhythmias at least every 30 minutes for 2 hours initially.
b. Assess for chest pain. If dysrhythmias or chest pain occurs, notify the PHCP.
c. Monitor peripheral pulses and the color, warmth, and sensation of the extremity distal to the insertion site at least every 30 minutes for 2 hours initially.
d. Notify the PHCP if the client reports numbness and tingling; if the extremity becomes cool, pale, or cyanotic; or if loss of the peripheral pulses occurs. This could indicate clot formation and is an emergency.
e. Apply a sandbag or compression device (if prescribed) to the insertion site to provide additional pressure if required.
f. Monitor for bleeding; if bleeding occurs, apply manual pressure immediately and notify the PHCP.
g. Monitor for hematoma; if a hematoma develops, notify the PHCP.
h. If the PHCP uses a vascular closure device to seal the arterial puncture site, there is no need for prolonged compression or bed rest, and clients may be out of bed in 1 to 2 hours according to manufacturing recommendations for the product used.
i. If no vascular closure device was inserted, keep the extremity extended for 4 to 6 hours, as prescribed, to prevent arterial occlusion. Maintain strict bed rest for 6 to 12 hours, as prescribed; however, the client may turn from side to side. Do not elevate the head of the bed more than 15 degrees. If the antecubital vessel was used, immobilize the arm with an armboard.
j. Encourage fluid intake, if not contraindicated, to promote renal excretion of the dye and to replace fluid loss caused by the osmotic diuretic effect of the dye.
k. Monitor for nausea, vomiting, rash, or other signs of hypersensitivity to the dye.

Y. Intravascular ultrasonography (IVUS): A catheter with a transducer is used as an alternative to injecting a dye into the coronary arteries and detects plaque distribution and composition; it also detects arterial dissection and the degree of stenosis of an occluded artery.

III. Therapeutic Management

A. Percutaneous transluminal coronary angioplasty (PTCA)
1. Description (Fig. 53.3)
a. An invasive, nonsurgical technique in which one or more coronary arteries are dilated with a balloon catheter to open the vessel lumen and improve arterial blood flow
b. PTCA may be used for clients with an evolving MI, alone or in combination with medications, to achieve reperfusion.
c. The client can experience reocclusion after the procedure; thus, the procedure may need to be repeated.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

d. Complications can include arterial dissection or rupture, embolization of plaque fragments, spasm, and acute MI.

e. Firm commitment is needed on the client's part to stop smoking, adhere to diet restrictions, lose weight, alter the exercise pattern, and stop any behaviors that lead to progressive artery occlusion.

2. Preprocedure interventions

a. Similar to preprocedure interventions for cardiac catheterization

b. The PHCP may prescribe preprocedure medications, including acetylsalicylic acid.

c. Instruct the client that chest pain may occur during balloon inflation and to report it if it does occur.

3. Postprocedure interventions

a. Similar to postprocedure intervention following cardiac catheterization

b. Administer anticoagulants and antiplatelets as prescribed to prevent thrombus formation.

c. IV nitroglycerin may be prescribed to prevent coronary artery vasospasm.

d. Encourage fluids, if not contraindicated, to enhance renal excretion of dye.

e. Instruct the client in the administration of prescribed medications; daily acetylsalicylic acid (aspirin) may be prescribed.

f. Assist the client with planning lifestyle modifications.

B. Laser-assisted angioplasty

1. Description

a. A laser probe is advanced through a cannula similar to that used for PTCA.

b. Used for clients with small occlusions in the coronary arteries, also the distal superficial femoral, proximal popliteal and common iliac arteries

c. Heat from the laser vaporizes the plaque to open the occluded artery.

2. Preprocedure and postprocedure interventions

a. Care is similar to that for PTCA.

b. Monitor for complications of coronary dissection, acute occlusion, perforation, embolism, and MI.

C. Coronary artery stents

1. Description

a. Coronary artery stents are used with PTCA to provide a supportive scaffold to eliminate the risk of acute coronary vessel closure and to improve long-term patency of the vessel.

b. A balloon catheter bearing the stent is inserted into the coronary artery and positioned at the site of occlusion; balloon inflation deploys the stent.

c. When placed in the coronary artery, the stent reopens the blocked artery.

2. Preprocedure and postprocedure interventions

a. Care is similar to that for PTCA.

b. Acute thrombosis is a major concern following the procedure; the client is placed on antiplatelet therapy such as clopidogrel and acetylsalicylic acid (aspirin) for several months following the procedure. The length of time for antiplatelet therapy is determined by the type of stent (metal or medication-coated).

c. Monitor for complications of the procedure such as stent migration or occlusion, coronary artery dissection, and bleeding resulting from anticoagulation.

D. Atherectomy

1. Description

a. Atherectomy removes plaque from a coronary artery by the use of a cutting chamber on the inserted catheter or a rotating blade that pulverizes the plaque.

b. Atherectomy is also used to improve blood flow to ischemic limbs in individuals with peripheral arterial disease.

2. Preprocedure and postprocedure interventions

a. Care is similar to that for PTCA.

b. Monitor for complications of perforation, embolus, and reocclusion.

E. Transmyocardial revascularization

1. May be used for clients with widespread atherosclerosis involving vessels that are too small and numerous for replacement or balloon catheterization; performed through a small chest incision

2. Transmyocardial revascularization uses a high-powered laser that creates 20 to 24 channels through the muscle of the left ventricle; blood enters these small channels, providing the affected region of the heart with oxygenated blood.

3. The opening on the surface of the heart heals; however, the main channels remain and perfuse the myocardium.

F. Coronary artery bypass grafting (Fig. 53.4)

1. Description

a. The occluded coronary arteries are bypassed with the client's own venous or arterial blood vessels.

b. The saphenous vein, internal mammary artery, or other arteries may be used to bypass lesions in the coronary arteries.

c. Coronary artery bypass grafting is performed when the client does not respond to medical management of coronary artery disease or when vessels are severely occluded.

d. A minimally invasive direct coronary artery bypass (MIDCAB) may be an option for some clients who have a lesion in the LAD artery; a sternal incision is not required (usually a 2-inch [5-cm] left thoracotomy incision is done), and cardiopulmonary bypass is not required in this procedure.

Telegram & Insta: NCLEX_RN_Edu

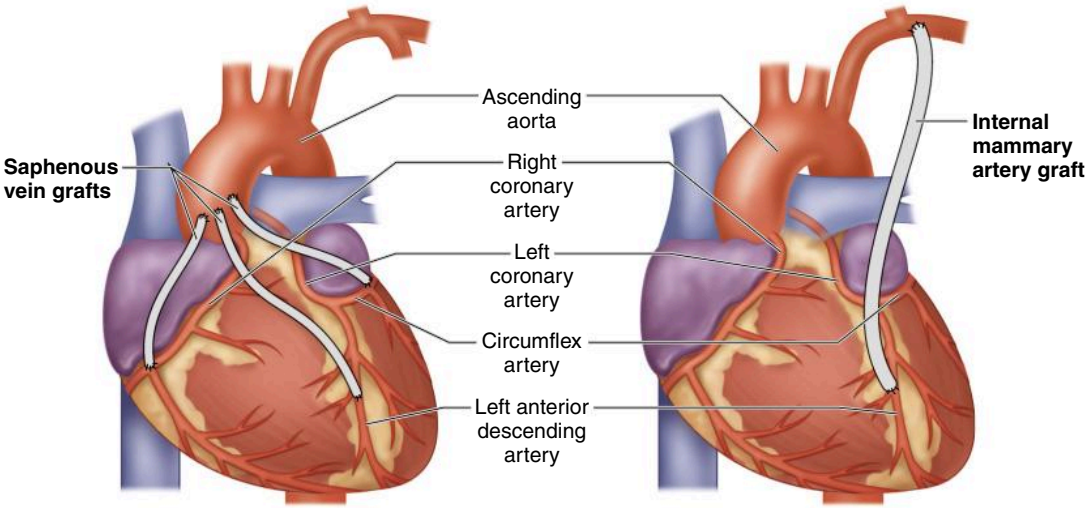


FIG. 53.4 Two methods of coronary artery bypass grafting. The procedure used depends on the nature of the coronary disease, the condition of the vessels available for grafting, and the client's health status.

2. Preoperative interventions
   - **a.** Familiarize the client and family with the cardiac surgical critical care unit.
   - **b.** Inform the client to expect a sternal incision, possible arm or leg incision(s), one or two chest tubes, a Foley catheter, and several IV fluid catheters.
   - **c.** Inform the client that an endotracheal tube will be in place for a short period of time and that they will be unable to speak.
   - **d.** Advise the client they will be on mechanical ventilation and to breathe with the ventilator and not fight it.
   - **e.** Instruct the client that postoperative pain is expected and that pain medication will be available.
   - **f.** Instruct the client in how to splint the chest incision, cough and deep breathe, use the incentive spirometer, and perform arm and leg exercises.
   - **g.** Encourage the client and family to discuss anxieties and fears related to surgery.
   - **h.** Note that prescribed medications may be discontinued preoperatively (usually, diuretics 2 to 3 days before surgery, digoxin 12 hours before surgery, and aspirin and anticoagulants 1 week before surgery).
   - **i.** Administer medications as prescribed, which may include potassium chloride, antihypertensives, antidysrhythmics, and antibiotics.
3. Cardiac surgical unit postoperative interventions (see Clinical Judgment: Analyze Cues Box)
   - **a.** Mechanical ventilation may continue for 6 to 24 hours.
   - **b.** Heart rate and rhythm, pulmonary artery and arterial pressures, urinary output, and neurological status are monitored closely.
   - **c.** Mediastinal and pleural chest tubes to the water seal drainage system with prescribed suction are present; drainage exceeding 100 to 150 mL/hr is reported to the PHCP.
   - **d.** Epicardial pacing wires are covered with sterile caps or connected to a temporary pacemaker generator; all equipment in use must be properly grounded to prevent microshock.
   - **e.** Fluid and electrolyte balance is monitored closely; fluids are usually restricted to 1500 to 2000 mL because of postoperative edema.
   - **f.** The blood pressure is monitored closely, because hypotension can cause collapse of a vein graft; hypertension can cause increased pressure, promoting leakage from the suture line, causing bleeding.
   - **g.** Temperature is monitored and rewarming procedures are initiated using warm or thermal blankets if the temperature drops below 96.8° F (36.0° C); rewarm the client no faster than 1.8 degrees/hr to prevent shivering, and discontinue rewarming procedures when the temperature approaches 98.6° F (37.0° C).
   - **h.** Potassium is administered intravenously as prescribed to maintain the potassium level between 4 and 5 mEq/L (4 to 5 mmol/L) to prevent dysrhythmias.
   - **i.** The client is monitored for signs of cardiac tamponade, which include sudden cessation of previously heavy mediastinal drainage, jugular vein distention with clear lung sounds, equalization of right atrial (RA) pressure and pulmonary artery wedge pressure, and pulsus paradoxus.
   - **j.** Pain is monitored, differentiating sternotomy pain from anginal pain, which would indicate graft failure.

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: ANALYZE CUES

The nurse is caring for a client who had cardiac surgery 24 hours ago. The client has had a urine output averaging 20 mL/hr for 2 hours. The client received a single bolus of 500 mL of intravenous fluid. Urine output for the subsequent hour was 25 mL. Daily laboratory results indicate that the blood urea nitrogen level is 45 mg/dL (16 mmol/L) and the serum creatinine level is 2.2 mg/dL (194 mcmol/L). The nurse analyzes these findings and interprets that the client is experiencing acute kidney injury and notifies the surgeon.

4. Transfer of the client from the cardiac surgical unit
   - **a.** Monitor vital signs, level of consciousness, and peripheral perfusion.
   - **b.** Monitor for dysrhythmias.
   - **c.** Auscultate lungs and assess respiratory status.
   - **d.** Encourage the client to splint the incision, cough, deep-breathe, and use the incentive spirometer to raise secretions and prevent atelectasis.
   - **e.** Monitor temperature and white blood cell count, which, if elevated after 3 to 4 days, indicate infection.
   - **f.** Provide adequate fluids and hydration as prescribed to liquefy secretions.
   - **g.** Assess suture line and chest tube insertion sites for redness, purulent discharge, and signs of infection.
   - **h.** Assess sternal suture line for instability, which may indicate infection.
   - **i.** Guide the client to gradually resume activity.
   - **j.** Assess the client for tachycardia, **postural (orthostatic) hypotension**, and fatigue before, during, and after activity.
   - **k.** Discontinue activities if the BP drops more than 10 to 20 mm Hg or if the pulse increases more than 10 beats per minute.
   - **l.** Monitor episodes of pain closely.
   - **m.** See Box 53.2 for home care instructions.

G. Heart transplantation
1. A donor heart from an individual with a comparable body weight and ABO compatibility is transplanted into a recipient within less than 6 hours of procurement.
2. The surgeon removes the diseased heart, leaving the posterior portion of the atria to serve as an anchor for the new heart.
3. Because a remnant of the client's atria remains, two unrelated P waves are noted on the ECG.

BOX 53.2 Home Care Instructions for the Client After Cardiac Surgery

- Progressive return to activities at home
- Limiting of pushing or pulling activities for 6 weeks following discharge
- Maintenance of incisional care and recording signs of redness, swelling, or drainage
- Sternotomy incision heals in about 6 to 8 weeks
- Avoidance of crossing legs; wearing elastic hose as prescribed until edema subsides, and elevating the surgical limb (if used to obtain the graft) when sitting in a chair
- Use of prescribed medications
- Dietary measures, including the avoidance of saturated fats and cholesterol and the use of salt
- Resumption of sexual intercourse on the advice of the primary health care provider or cardiologist after exercise tolerance is assessed (usually, if the client can walk 1 block or climb 2 flights of stairs without symptoms, it is safe to resume sexual activity)

4. The transplanted heart is denervated and unresponsive to vagal stimulation; because the heart is denervated, clients do not experience angina.
5. Symptoms of heart rejection include hypotension, dysrhythmias, weakness, fatigue, and dizziness.
6. Endomyocardial biopsies are performed at regularly scheduled intervals and whenever rejection is suspected.
7. The client requires lifetime immunosuppressive therapy.
8. Strict aseptic technique and vigilant handwashing must be maintained when caring for the posttransplantation client because of increased risk for infection from immunosuppression.
9. The heart rate approximates 100 beats per minute and responds slowly to exercise or stress with regard to increases in heart rate, **contractility**, and **cardiac output**.

IV. Cardiac Dysrhythmias (see Clinical Judgment: Analyze Cues Box)

A. Normal sinus rhythm (Fig. 53.5)
1. Rhythm originates from the SA node.
2. Description
   - **a.** Atrial and ventricular rhythms are regular.
   - **b.** Atrial and ventricular rates are 60 to 100 beats per minute (Fig. 53.6 and Box 53.3).
   - **c.** PR interval and QRS width are within normal limits.

B. Sinus bradycardia
1. Description
   - **a.** Atrial and ventricular rhythms are regular.
   - **b.** Atrial and ventricular rates are less than 60 beats per minute.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

FIG. 53.5 Normal sinus rhythm. Both atrial and ventricular rhythms are essentially regular (a slight variation in rhythm is normal). Atrial and ventricular rates are both 83 beats per minute. There is one P wave before each QRS complex, and all P waves are of a consistent morphology, or shape. The PR interval measures 0.18 seconds and is constant; the QRS complex measures 0.06 seconds and is constant.

FIG. 53.6 Each segment between the dark lines (above the monitor strip) represents 3 seconds when the monitor is set at a speed of 25 mm/second. To estimate the ventricular rate, count the QRS complexes in a 6-second strip and then multiply that number by 10 to estimate the heart rate for 1 minute. In this example, there are 9 QRS complexes in 6 seconds. Therefore, the heart rate can be estimated as 90 beats per minute.

BOX 53.3 Determination of Heart Rate Using 6-Second Strip Method

- The method can be used to determine heart rate for regular and irregular rhythms.
- To determine atrial rate, count the number of P waves in 6 seconds and multiply by 10 to obtain a full minute rate.
- To determine ventricular rate, count the number of R waves or QRS complexes in 6 seconds and multiply by 10 to obtain a full minute rate.
- For accuracy, timing should begin on the P wave or the QRS complex and end exactly at 30 large blocks later.

c. PR interval and QRS width are within normal limits.
d. Treatment may be necessary if the client is symptomatic (signs of decreased cardiac output).
e. A low heart rate may be normal for some individuals, such as athletes.

2. Interventions
a. Attempt to determine the cause of sinus bradycardia; withhold medication suspected of causing the bradycardia and notify the PHCP.
b. Administer oxygen as prescribed for the symptomatic client.
c. Administer atropine sulfate as prescribed to increase the heart rate to 60 beats per minute.
d. Be prepared to apply a noninvasive (transcutaneous) pacemaker initially if the atropine sulfate does not increase the heart rate sufficiently.
e. Avoid additional doses of atropine sulfate, because this will induce tachycardia.
f. Monitor for hypotension, and administer fluids intravenously as prescribed.
g. Depending on the cause of the bradycardia, the client may need a permanent pacemaker.

C. Sinus tachycardia

1. Description
a. Atrial and ventricular rates are 100 to 180 beats per minute.
b. Atrial and ventricular rhythms are regular.
c. PR interval and QRS width are within normal limits.

2. Interventions
a. Identify the cause of the tachycardia.
b. Decrease the heart rate to normal by treating the underlying cause.

D. Atrial fibrillation (Fig. 53.7)

1. Description
a. Multiple rapid impulses from many foci depolarize in the atria in a totally disorganized manner at a rate of 350 to 600 times per minute.
b. The atria quiver, which can lead to the formation of thrombi.
c. Usually no definitive P wave can be observed, only fibrillatory waves before each QRS.

2. Interventions
a. Administer oxygen.
b. Administer anticoagulants as prescribed because of the risk of emboli.
c. Administer cardiac medications as prescribed to control the ventricular rhythm and assist in the maintenance of cardiac output.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

FIG. 53.7 Atrial dysrhythmias—atrial fibrillation.

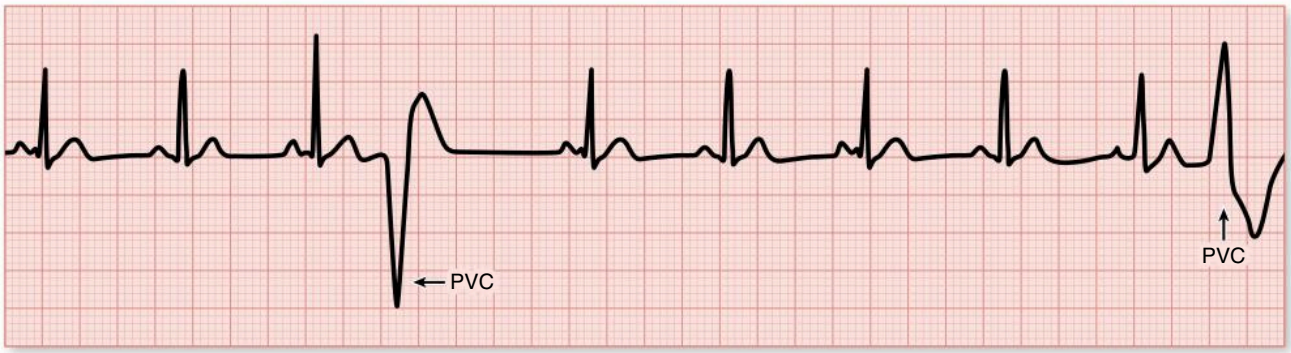

FIG. 53.8 Ventricular dysrhythmias—normal sinus rhythm with multifocal premature ventricular contractions (PVCs; one negative and the other positive).

d. Prepare the client for cardioversion as prescribed.
e. Instruct the client in the use of medications as prescribed to control the dysrhythmia.

E. Premature ventricular contractions (PVCs; Fig. 53.8 and Box 53.4)
1. Description
a. Early ventricular contractions result from increased irritability of the ventricles.
b. PVCs frequently occur in repetitive patterns such as bigeminy, trigeminy, and quadrigeminy.
c. The QRS complexes may be unifocal or multifocal.
2. Interventions
a. Identify the cause and treat on the basis of the cause.
b. Evaluate oxygen saturation to assess for hypoxemia, which can cause PVCs.
c. Evaluate electrolytes, particularly the potassium level, because hypokalemia can cause PVCs.
d. Oxygen and medication may be prescribed in the case of acute myocardial ischemia or MI.

For the client experiencing PVCs, notify the PHCP or cardiologist if the client complains of chest pain or if the PVCs increase in frequency, are multifocal, occur on the T wave (R-on-T), or occur in runs of ventricular tachycardia.

BOX 53.4 Premature Ventricular Contractions

Bigeminy: Premature ventricular contraction (PVC) every other heartbeat
Trigeminy: PVC every third heartbeat
Quadrigeminy: PVC every fourth heartbeat
Couplet or pair: Two sequential PVCs
Unifocal: Uniform upward or downward deflection, arising from the same ectopic focus
Multifocal: Different shapes, with the impulse generation from different sites
R-on-T phenomenon: PVC falls on the T wave of the preceding beat; may precipitate ventricular fibrillation

F. Ventricular tachycardia (VT; Fig. 53.9)
1. Description
a. VT occurs because of a repetitive firing of an irritable ventricular ectopic focus at a rate of 140 to 250 beats per minute or more.
b. VT may present as a paroxysm of three self-limiting beats or more, or may be a sustained rhythm.
c. VT can lead to cardiac arrest.
2. Stable client with sustained VT (with pulse and no signs or symptoms of decreased cardiac output)
a. Administer oxygen as prescribed.
b. Administer antidysrhythmics as prescribed.
3. Unstable client with VT (with pulse and signs and symptoms of decreased cardiac output)
a. Administer oxygen and antidysrhythmic therapy as prescribed.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

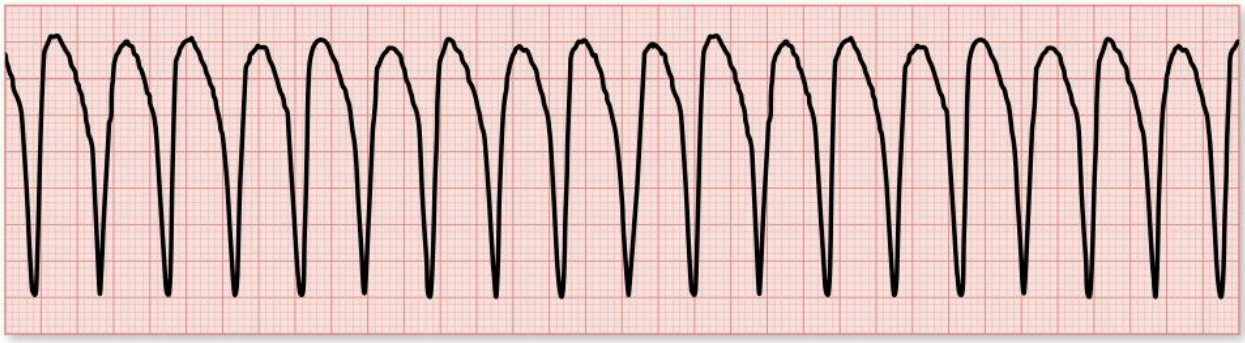

FIG. 53.9 Ventricular dysrhythmias—sustained ventricular tachycardia at a rate of 166 beats per minute.

FIG. 53.10 Ventricular dysrhythmias—coarse ventricular fibrillation.

Telegram & Insta: NCLEX_RN_Edu

b. Prepare for synchronized cardioversion if the client is unstable.
c. The PHCP may attempt cough cardiopulmonary resuscitation (CPR) by asking the client to cough hard every 1 to 3 seconds.

4. Pulseless client with VT: Defibrillation and CPR

G. Ventricular fibrillation (VF; Fig. 53.10)

1. Description
a. Impulses from many irritable foci in the ventricles fire in a totally disorganized manner.
b. VF is a chaotic rapid rhythm in which the ventricles quiver and there is no cardiac output.
c. VF is fatal if not successfully resolved within 3 to 5 minutes.
d. Client is unconscious with no pulse, BP, respirations, or heart sounds.

2. Interventions
a. Initiate CPR until a defibrillator is available.
b. The client is defibrillated immediately with 120 to 200 joules (biphasic defibrillator) or 360 joules (monophasic defibrillator); check the entire length of the client 3 times to make sure no one is touching the client or the bed; when clear, proceed with defibrillation.
c. CPR is continued for 2 minutes, and the cardiac rhythm is reassessed to determine the need for further countershock.
d. Administer oxygen as prescribed.
e. Administer antidysrhythmic therapy as prescribed.

CLINICAL JUDGMENT: ANALYZE CUES BOX

The nurse is caring for clients in the telemetry unit and notes that a client with sinus rhythm has a premature ventricular contraction that falls on the T wave of the preceding beat. The client's rhythm suddenly changes to one with no P waves, no definable QRS complexes, and coarse wavy lines of varying amplitude. The nurse analyzes these findings and determines that the client is experiencing ventricular fibrillation. The nurse would immediately initiate CPR, call the Rapid Response Team, and prepare for defibrillation.

H. Guidelines for performing adult CPR

1. Follow CAB (compressions, airway, breathing) guidelines. If a victim is noted to be not breathing or only gasping, activate the emergency response system and obtain an automated external defibrillator (AED) or monophasic or biphasic defibrillator, depending on the setting and equipment available.

2. For updated information, refer to the American Heart Association. The latest update for adult CPR can be located at American Heart Association (2020). Highlights of the 2020 American Heart Association Guidelines for CPR and ECC. p. 11 at https://professional.heart.org/en/science-news/2020-aha-guidelines-for-cpr-and-ecc

Telegram & Insta: NCLEX_RN_Edu

V. Management of Dysrhythmias

A. Vagal maneuvers

1. Description: Vagal maneuvers induce vagal stimulation of the cardiac conduction system and are used to terminate supraventricular tachydysrhythmias.

2. Carotid sinus massage

a. The client turns the head away from the side to be massaged.

b. The PHCP massages over one carotid artery for a few seconds to determine whether a change in cardiac rhythm occurs.

c. The client must be on a cardiac monitor; an electrocardiographic rhythm strip before, during, and after the procedure should be documented on the chart.

d. Have a defibrillator and resuscitative equipment available.

e. Monitor vital signs, cardiac rhythm, and level of consciousness following the procedure.

3. Valsalva maneuver

a. The PHCP instructs the client to bear down or induces the client's gag reflex to stimulate a vagal response.

b. Monitor the heart rate, rhythm, and BP.

c. Observe the cardiac monitor for a change in rhythm.

d. Record an electrocardiographic rhythm strip before, during, and after the procedure.

e. Provide an emesis basin if the gag reflex is stimulated, and initiate precautions to prevent aspiration.

f. Have a defibrillator and resuscitative equipment available.

B. Cardioversion

1. Description

a. Cardioversion is synchronized countershock to convert an undesirable rhythm to a stable rhythm.

b. Cardioversion can be an elective procedure performed by the PHCP for stable tachydysrhythmias resistant to medical therapies or an emergent procedure for hemodynamically unstable ventricular or supraventricular tachydysrhythmias.

c. A lower amount of energy is used than with defibrillation.

d. The defibrillator is synchronized to the client's R wave to avoid discharging the shock during the vulnerable period (T wave).

e. If the defibrillator is not synchronized, it could discharge on the T wave and cause VF.

2. Preprocedure interventions

a. If an elective procedure, ensure that informed consent is obtained.

b. Administer sedation as prescribed.

c. If an elective procedure, hold digoxin for 48 hours preprocedure as prescribed to prevent postcardioversion ventricular irritability.

d. If an elective procedure for atrial fibrillation or atrial flutter, the client should receive anticoagulant therapy for 4 to 6 weeks preprocedure, and a transesophageal echocardiogram (TEE) should be performed to rule out clots in the atria prior to the procedure.

3. During the procedure

a. Ensure that the skin is clean and dry in the area where the electrode pads/hands-off pads will be placed.

b. Stop the oxygen during the procedure to avoid a fire hazard.

c. Be sure that no one is touching the bed or the client when delivering the countershock (check the entire length of the client 3 times).

4. Postprocedure interventions

a. Priority assessment includes ability of the client to maintain the airway and breathing.

b. Resume oxygen administration as prescribed.

c. Assess vital signs.

d. Assess level of consciousness.

e. Monitor cardiac rhythm.

f. Monitor for indications of successful response, such as conversion to sinus rhythm, strong peripheral pulses, an adequate BP, and adequate urine output.

g. Assess the skin on the chest for evidence of burns from the edges of the pads.

C. Defibrillation

1. Defibrillation is an asynchronous countershock used to terminate pulseless VT or VF.

2. The defibrillator is charged to 120 to 200 joules (biphasic) or 360 joules (monophasic) for 1 countershock from the defibrillator, and then CPR is resumed immediately and continued for five cycles or about 2 minutes.

3. Reassess the rhythm after 2 minutes, and if VF or pulseless VT continues, the defibrillator is charged to give a second shock at the same energy level previously used.

4. Resume CPR after the shock, and continue with the life support protocol.

! Before defibrillating a client, be sure that the oxygen is shut off to avoid the hazard of fire, and be sure that no one is touching the bed or the client.

D. Use of pad electrodes

1. One pad is placed at the third intercostal space to the right of the sternum; the other is placed at the fifth intercostal space on the left midaxillary line.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Avoid placing pads directly over breast tissue, medication patches, or an implanted device.
3. Pads for hands-off biphasic defibrillation may be applied in an anterior-posterior position or apex-posterior position.
4. Apply firm pressure of at least 25 lb to each of the pads.
5. Be sure that no one is touching the bed or the client when delivering the countershock.

E. Automated external defibrillator (AED)
1. An AED is used for prehospital cardiac arrest.
2. Place the client on a firm, dry surface.
3. Turn on the AED and follow the voice prompts.
4. Place the electrode patches in the correct position on the client's chest.
5. Stop CPR.
6. Ensure that no one is touching the client to avoid motion artifact during rhythm analysis.
7. The machine will advise whether a shock is necessary.
8. Shocks are recommended for pulseless VT or VF only (usually three shocks are delivered).
9. If unsuccessful, CPR is continued for 1 minute and then another series of shocks is delivered.

F. Automated implantable cardioverter-defibrillator (AICD)
1. Description
   a. An AICD monitors cardiac rhythm and detects and terminates episodes of VT and VF by delivering 25 to 30 joules up to 4 times, if necessary.
   b. An AICD is used in clients with episodes of spontaneous sustained VT or VF unrelated to an MI or in clients whose medication therapy has been unsuccessful in controlling life-threatening dysrhythmias.
   c. Transvenous electrode leads are placed in the right atrium and ventricle in contact with the endocardium; leads are used for sensing, pacing, and delivery of cardioversion or defibrillation.
   d. The generator is most commonly implanted in the left pectoral region.
2. Client education
   a. Instruct the client in the basic functions of the AICD.
   b. Know the rate cutoff of the AICD and the number of consecutive shocks that it will deliver.
   c. Wear loose-fitting clothing over the AICD generator site.
   d. Instruct the client on activities to avoid, including contact sports, to prevent trauma to the AICD generator and lead wires.
   e. Report any fever, redness, swelling, or drainage from the insertion site.
   f. Report symptoms of fainting, nausea, weakness, blackouts, and rapid pulse rates to the PHCP.
   g. During shock discharge, the client may feel faint or short of breath.
   h. Instruct the client to sit or lie down if a shock is felt and to notify the PHCP.
   i. Advise the client to maintain a log of the date, time, and activity preceding the shock; the symptoms preceding the shock; and post-shock sensations.
   j. Instruct the client and family in how to access the emergency medical system.
   k. Encourage the family to learn CPR.
   l. Instruct the client to avoid electromagnetic fields directly over the AICD, because they can inactivate the device.
   m. Instruct the client to move away from the magnetic field immediately if beeping tones are heard, and to notify the PHCP.
   n. Keep an AICD identification card in the wallet, and obtain and wear a MedicAlert bracelet.
   o. Inform all PHCPs that an AICD has been inserted; certain diagnostic tests, such as MRI, and procedures using diathermy or electrocautery interfere with AICD function.

VI. Pacemakers

A. Description: Temporary or permanent device that provides electrical stimulation and maintains the heart rate when the client's intrinsic pacemaker fails to provide an adequate rate

B. Settings
1. A synchronous (demand) pacemaker senses the client's rhythm and paces only if the client's intrinsic rate falls below the set pacemaker rate for stimulating depolarization.
2. An asynchronous (fixed rate) pacemaker paces at a preset rate regardless of the client's intrinsic rhythm and is used when the client is asystolic or profoundly bradycardic.
3. Overdrive pacing suppresses the underlying rhythm in tachydysrhythmias so that the sinus node will regain control of the heart.

C. Spikes
1. When a pacing stimulus is delivered to the heart, a spike (straight vertical line) is seen on the monitor or ECG strip.
2. Spikes precede the chamber being paced; a spike preceding a P wave indicates that the atrium is paced, and a spike preceding the QRS complex indicates that the ventricle is being paced.
3. An atrial spike followed by a P wave indicates atrial depolarization, and a ventricular spike followed by a QRS complex represents ventricular depolarization; this is referred to as *capture*.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

D. Temporary pacemakers

1. Noninvasive transcutaneous pacing

a. Noninvasive transcutaneous pacing is used as a temporary emergency measure in the profoundly bradycardic or asystolic client until invasive pacing can be initiated.

b. Large electrode pads are placed on the client's chest and back and connected to an external pulse generator.

c. Wash the skin with soap and water before applying electrodes.

d. It is not necessary to shave the hair or apply alcohol or tinctures to the skin.

e. Place the posterior electrode between the spine and left scapula behind the heart, avoiding placement over bone.

f. Place the anterior electrode between V2 and V5 positions over the heart.

g. Do not place the anterior electrode over breast tissue; rather, displace the breast tissue and place the electrode under the breast.

h. Do not take the pulse or BP on the left side; the results will not be accurate because of the muscle twitching and electrical current.

i. Ensure that electrodes are in good contact with the skin.

j. Set pacing rate as prescribed; establish stimulation threshold to ensure capture.

k. If loss of capture occurs, assess the skin contact of the electrodes and increase the current until capture is regained.

l. Evaluate the client for discomfort from cutaneous and muscle stimulation; administer analgesics as needed.

2. Invasive transvenous pacing

a. Pacing lead wire is placed through the antecubital, femoral, jugular, or subclavian vein into the right atrium or right ventricle so that it is in direct contact with the endocardium.

b. Monitor the pacemaker insertion site.

c. Restrict client movement to prevent lead wire displacement.

3. Invasive epicardial pacing—applied by using a transthoracic approach; the lead wires are threaded loosely on the epicardial surface of the heart after cardiac surgery.

4. Reducing the risk of microshock

a. Use only inspected and approved equipment.

b. Insulate the exposed portion of wires with plastic or rubber material (fingers of rubber gloves) when wires are not attached to the pulse generator; cover with nonconductive tape.

c. Ground all electrical equipment, using a three-pronged plug.

d. Wear gloves when handling exposed wires.

e. Keep dressings dry.

Vital signs are monitored and cardiac monitoring is done continuously for the client with a temporary pacemaker.

E. Permanent pacemakers

1. Pulse generator is internal and surgically implanted in a subcutaneous pocket below the clavicle.

2. The leads are passed transvenously via the cephalic or subclavian vein to the endocardium on the right side of the heart; postoperatively, limitation of arm movement on the operative side is required to prevent lead wire dislodgment.

3. Permanent pacemakers may be single-chambered, in which the lead wire is placed in the chamber to be paced; or dual-chambered, with lead wires placed in both the right atrium and the right ventricle.

4. Biventricular pacing of the ventricles allows for synchronized depolarization and is used for moderate to severe heart failure to improve cardiac output.

5. A permanent pacemaker is programmed when inserted and can be reprogrammed if necessary by noninvasive transmission from an external programmer to the implanted generator.

6. Pacemakers may be powered by a lithium battery with an average life span of 10 years, nuclear-powered with a life span of 20 years or longer, or designed to be recharged externally.

7. Pacemaker function can be checked in the PHCP's office or clinic by a pacemaker interrogator or programmer or from home, using a special telephone transmitter device.

8. Client teaching (Box 53.5).

VII. Coronary Artery Disease

A. Description

1. Coronary artery disease is a narrowing or obstruction of one or more coronary arteries as a result of atherosclerosis, which is an accumulation of lipid-containing plaque in the arteries (Fig. 53.11).

2. The disease causes decreased perfusion of myocardial tissue and inadequate myocardial oxygen supply, leading to hypertension, angina, dysrhythmias, MI, heart failure, and death.

3. Collateral circulation (more than one artery supplying a muscle with blood) develops over time in response to chronic ischemia; therefore, an occlusion of a coronary artery in a younger individual is more likely to be lethal than one in an older individual.

4. Symptoms of ischemia occur when the coronary artery is occluded to the point of inadequate blood supply to the cardiac muscle.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 53.5 Pacemakers: Client Education

- Instruct the client about the pacemaker, including the programmed rate.
- Instruct the client in the signs of battery failure and when to notify the PHCP or cardiologist.
- Instruct the client to report any fever, redness, swelling, or drainage from the insertion site.
- Report signs of dizziness, weakness or fatigue, swelling of the ankles or legs, chest pain, or shortness of breath.
- Keep a pacemaker identification card in the wallet, and obtain and wear a MedicAlert bracelet.
- Instruct the client in how to take the pulse, to take the pulse daily, and to maintain a diary of pulse rates.
- Wear loose-fitting clothing over the pulse generator site.
- Avoid contact sports.
- Inform all PHCPs that a pacemaker has been inserted.
- Instruct the client to inform airport security that they have a pacemaker, because the pacemaker may set off the security detector.
- Instruct the client that most electrical appliances can be used without any interference with the functioning of the pacemaker; however, advise the client not to operate electrical appliances directly over the pacemaker site.
- Avoid transmitter towers and antitheft devices in stores.
- Instruct the client that if any unusual feelings occur when near any electrical devices, to move 5 to 10 feet away and check the pulse.
- Instruct the client about the methods of monitoring the function of the device.
- Emphasize the importance of follow-up with the PHCP.
- Use cell phones on the side opposite the pacemaker. Do not carry a cell phone in a pocket directly over the pacemaker.

5. Coronary artery narrowing is significant if the lumen diameter of the left main artery is reduced by at least 50% or if any major branch is reduced at least 75%.
6. The goal of treatment is to alter the atherosclerotic progression.

B. Assessment
1. Possibly normal findings during asymptomatic periods
2. Chest pain
3. Palpitations
4. Dyspnea
5. Syncope
6. Cough or hemoptysis
7. Excessive fatigue

C. Diagnostic studies
1. Electrocardiography
   - **a.** When blood flow is reduced and ischemia occurs, ST-segment depression, T-wave inversion, or both are noted; the ST segment returns to normal when the blood flow returns.
   - **b.** With infarction, cell injury results in ST-segment elevation, followed by T-wave inversion and an abnormal Q wave.

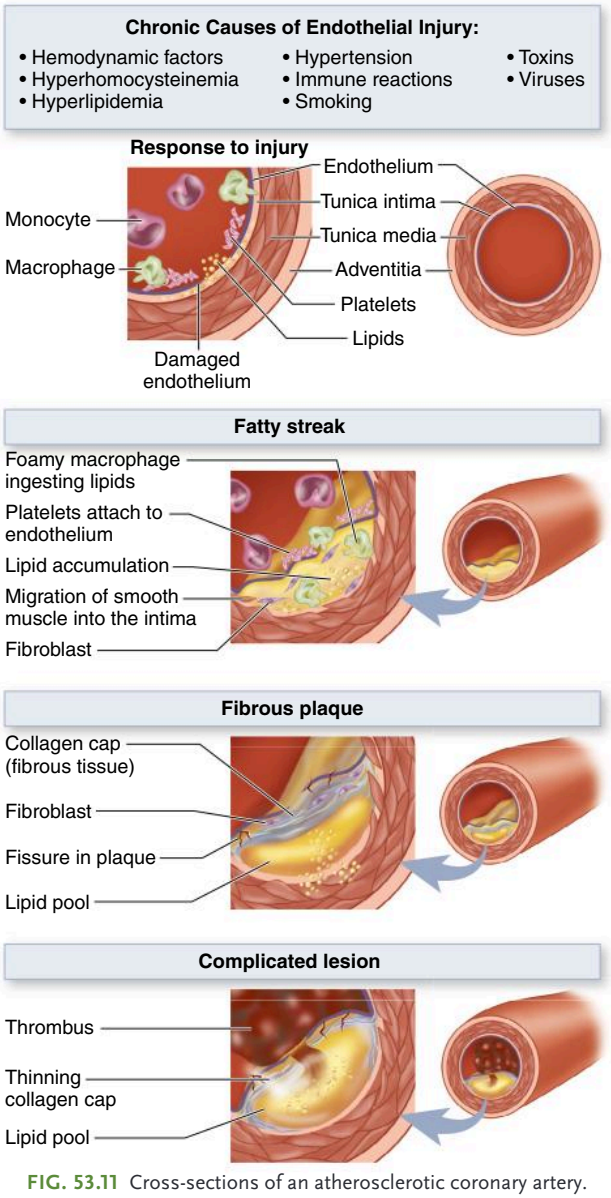

FIG. 53.11 Cross-sections of an atherosclerotic coronary artery.

2. Cardiac catheterization: Cardiac catheterization shows the presence and extent of atherosclerotic lesions.
3. Blood lipid levels
   - **a.** Blood lipid levels may be elevated.
   - **b.** Cholesterol-lowering medications may be prescribed to reduce the development of atherosclerotic plaques.

D. Interventions
1. Assist the client to identify modifiable risk factors and to set goals to promote healthy lifestyle changes.
2. Assist the client to identify barriers to adherence with the therapeutic plan and to identify methods to overcome barriers.
3. Instruct the client regarding a low-calorie, low-sodium, low-cholesterol, and low-fat diet, with an increase in dietary fiber.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Stress that dietary changes should be incorporated for the rest of the client's life; instruct the client regarding prescribed medications.
5. Provide community resources to the client regarding exercise, smoking cessation, and stress reduction as appropriate.

E. Surgical procedures
1. PTCA to compress the plaque against the walls of the artery and dilate the vessel
2. Laser angioplasty to vaporize the plaque
3. Atherectomy to remove the plaque from the artery
4. Vascular stent to prevent the artery from closing and to prevent restenosis
5. Coronary artery bypass grafting past the occluded artery to improve blood flow to the myocardial tissue at risk for ischemia or infarction

F. Medications
1. Nitrates to dilate the coronary arteries and decrease **preload** and **afterload**
2. Calcium channel blockers to dilate coronary arteries and reduce vasospasm
3. Cholesterol-lowering medications to reduce the development of atherosclerotic plaques
4. Beta blockers to control hypertension

VIII. Angina

A. Description
1. Angina is chest pain resulting from myocardial ischemia caused by inadequate myocardial blood and oxygen supply.
2. Angina is caused by an imbalance between oxygen supply and demand.
3. Causes include obstruction of coronary blood flow resulting from atherosclerosis, coronary artery spasm, or conditions increasing myocardial oxygen consumption.

The goal of treatment for angina is to provide relief from the acute attack, correct the imbalance between myocardial oxygen supply and demand, and prevent the progression of the disease and further attacks to reduce the risk of MI.

B. Patterns of angina
1. Stable angina
   a. Also called exertional angina
   b. Occurs with activities that involve exertion or emotional stress; relieved with rest or nitroglycerin
   c. Usually has a stable pattern of onset, duration, severity, and relieving factors
2. Unstable angina
   a. Also called preinfarction angina
   b. Associated with worsening cardiac ischemia
   c. Occurs with an unpredictable degree of exertion or emotion and increases in occurrence, duration, and severity over time

TABLE 53.1 Characteristics of Pain: Angina and Myocardial Infarction

Angina	Myocardial Infarction
Can develop slowly or quickly	Occurs without cause, primarily early in the morning
Usually described as mild or moderate pain	Crushing substernal pain
Substernal, crushing, squeezing pain	May radiate to the jaw, back, and left arm
May radiate to the shoulders, arms, jaw, neck, and back	Lasts 30 minutes or longer
Usually lasts less than 5 minutes; however, can last up to 15 to 20 minutes	Is unrelieved by rest or nitroglycerin, and relieved only by opioids
Relieved by nitroglycerin or rest	

   d. Lasts longer than 15 minutes
   e. Pain may not be relieved with nitroglycerin.
3. Variant angina
   a. Also called Prinzmetal's or vasospastic angina
   b. Results from coronary artery spasm
   c. May occur at rest
   d. Attacks may be associated with ST-segment elevation noted on the ECG.
4. Intractable angina is a chronic, incapacitating angina unresponsive to interventions.

C. Assessment
1. Pain (Table 53.1)
   a. Pain can develop slowly or quickly.
   b. Pain usually is described as mild or moderate.
   c. Substernal, crushing, squeezing pain may occur.
   d. Pain may radiate to the shoulders, arms, jaw, neck, or back.
   e. Pain intensity is unaffected by inspiration and expiration.
   f. Pain usually lasts less than 5 minutes but may last 15 to 20 minutes.
   g. Pain is relieved by nitroglycerin or rest.
2. Dyspnea
3. Pallor
4. Sweating
5. Palpitations and tachycardia
6. Dizziness and syncope
7. Hypertension
8. Digestive disturbances

D. Diagnostic studies
1. Electrocardiography: Readings are normal during rest, with ST depression or T-wave inversion during an episode of pain.
2. Stress testing: Chest pain or changes in the ECG or vital signs during testing may indicate ischemia.
3. Troponin and cardiac enzyme levels: Findings are normal in angina.
4. Cardiac catheterization: Provides a definitive diagnosis by providing information about the patency of the coronary arteries.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

E. Interventions
1. Immediate management
a. Assess pain; institute pain relief measures.
b. Administer oxygen by nasal cannula as prescribed.
c. Assess vital signs and provide continuous cardiac monitoring and nitroglycerin as prescribed to dilate the coronary arteries, reduce the oxygen requirements of the myocardium, and relieve the chest pain.
d. Ensure that bed rest is maintained, place the client in semi-Fowler's position, and stay with the client.
e. Obtain a 12-lead ECG.
f. Establish an IV access route.
2. Following the acute episode
a. See section VII, D (Coronary Artery Disease, Interventions).
b. Assist the client to identify angina-precipitating events.
c. Instruct the client to stop activity and rest if chest pain occurs, and to sit down and take nitroglycerin as prescribed. The client is usually instructed to call emergency medical services if the nitroglycerin does not relieve the pain, and many PHCPs recommend that the client also chew an aspirin.

F. Surgical procedures: See section VII, E (Coronary Artery Disease, Surgical procedures).

G. Medications
1. See section VII, F (Coronary Artery Disease, Medications).
2. Antiplatelet therapy may be prescribed to inhibit platelet aggregation and reduce the risk of developing an acute MI.

IX. Myocardial Infarction

A. Description
1. MI occurs when myocardial tissue is abruptly and/or severely deprived of oxygen.
2. Ischemia can lead to necrosis of myocardial tissue if blood flow is not restored.
3. Infarction does not occur instantly but evolves over several hours.
4. Obvious physical changes do not occur in the heart until 6 hours after the infarction, when the infarcted area appears blue and swollen.
5. After 48 hours, the infarct turns gray, with yellow streaks developing as neutrophils invade the tissue.
6. By 8 to 10 days after infarction, granulation tissue forms.
7. Over 2 to 3 months, the necrotic area develops into a scar; scar tissue permanently changes the size and shape of the ventricle.

B. Location of MI (see Fig. 53.1)
1. Obstruction of the LAD artery results in anterior wall or septal MI, or both.
2. Obstruction of the circumflex artery results in posterior wall MI or lateral wall MI.
3. Obstruction of the right coronary artery results in inferior wall MI.

C. Risk factors
1. Atherosclerosis
2. Coronary artery disease
3. Elevated cholesterol levels
4. Smoking
5. Hypertension
6. Obesity
7. Physical inactivity
8. Impaired glucose tolerance
9. Stress

D. Diagnostic studies
1. Troponin level: Level rises within 3 hours and remains elevated for up to 7 to 10 days.
2. Total CK level: Level rises within 6 hours after the onset of chest pain and peaks within 18 hours after damage and death of cardiac tissue.
3. CK-MB isoenzyme: Peak elevation occurs 18 hours after the onset of chest pain and returns to normal 48 to 72 hours later.
4. Myoglobin: Level rises within 2 hours after cell death, with a rapid decline in the level after 7 hours.
5. White blood cell count: An elevated white blood cell count appears on the second day following the MI and lasts up to 1 week.
6. Electrocardiogram
a. ECG shows either ST segment elevation MI (STEMI), T-wave inversion, or NSTEMI; an abnormal Q wave may also present.
b. Hours to days after the MI, ST- and T-wave changes will return to normal, but the Q-wave changes usually remain permanently.
7. Cardiac catheterization may be done emergently to determine the extent and location of obstructions of the coronary arteries; this allows for use of PTCA and restoration of blood flow to the myocardium.
8. Diagnostic tests following the acute stage
a. Exercise tolerance test or stress test to assess for electrocardiographic changes and ischemia and to evaluate for medical therapy or identify clients who may need invasive therapy
b. Thallium scans to assess for ischemia or necrotic muscle tissue
c. Multigated cardiac blood pool imaging scans may be used to evaluate left ventricular function.
d. If not done urgently, cardiac catheterization to determine the coronary artery obstructions will be done after the client is stabilized.

E. Assessment
1. Pain (see Table 53.1)
a. Client may experience crushing substernal pain.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

b. Pain may radiate to the jaw, back, and left arm.
c. Pain may occur without cause, primarily early in the morning.
d. Pain is unrelieved by rest or nitroglycerin and is relieved only by opioids.
e. Pain lasts 30 minutes or longer.

2. Nausea and vomiting
3. Diaphoresis
4. Dyspnea
5. Dysrhythmias
6. Feelings of fear and anxiety, impending doom
7. Pallor, cyanosis, coolness of extremities
8. Women may experience atypical discomfort, shortness of breath, or fatigue and often present with non–ST-elevation myocardial infarction (NSTEMI) or T-wave inversion.
9. An older client may experience shortness of breath, pulmonary edema, dizziness, or altered mental status.

F. Complications of MI (Box 53.6)

G. Interventions, acute stage

⚠ Pain relief increases oxygen supply to the myocardium; administer morphine as a priority in managing pain in the client having an MI.

1. Obtain a description of the chest discomfort.
2. Administer oxygen and institute pain relief measures (morphine, nitroglycerin as prescribed).
3. Assess vital signs and cardiovascular status, and maintain cardiac monitoring.
4. Assess respiratory rate and breath sounds for signs of heart failure, as indicated by the presence of crackles or wheezes or dependent edema.
5. Place the client in a semi-Fowler's position to enhance comfort and tissue oxygenation; ensure bed rest and stay with the client.
6. Establish an IV access route.
7. Obtain a 12-lead ECG.
8. Monitor laboratory values.
9. Monitor for cardiac dysrhythmias, because tachycardia and PVCs frequently occur in the first few hours after MI; administer antidysrhythmics as prescribed.
10. Administer thrombolytic therapy, which may be prescribed within the first 6 hours of the coronary event if cardiac catheterization is not to be done emergently; monitor for signs of bleeding if the client is receiving thrombolytic therapy.
11. Assess for poor cardiac output, which may appear as cool diaphoretic skin and diminished or absent pulses.
12. Monitor the BP closely after administering medications; if the **systolic pressure** is lower than 100 mm Hg or 25 mm Hg lower than the previous reading, lower the head of the bed and notify the PHCP.
13. Administer beta blockers as prescribed to slow the heart rate and increase myocardial perfusion while reducing the force of myocardial contraction.
14. Provide reassurance to the client and family.

BOX 53.6 Complications of Myocardial Infarction

- Dysrhythmias
- Heart failure
- Pulmonary edema
- Cardiogenic shock
- Thrombophlebitis
- Pericarditis
- Mitral valve insufficiency
- Postinfarction angina
- Ventricular rupture
- Dressler's syndrome (a combination of pericarditis, pericardial effusion, and pleural effusion, which can occur several weeks to months following a myocardial infarction)

H. Interventions following the acute episode

1. Maintain bed rest as prescribed.
2. Allow the client to stand to void or use a bedside commode if prescribed.
3. Provide range-of-motion exercises to prevent thrombus formation and maintain muscle strength.
4. Progress to dangling legs at the side of the bed or out of bed to the chair for 30 minutes 3 times a day as prescribed.
5. Progress to ambulation in the client's room and to the bathroom and then in the hallway 3 times a day.
6. Monitor for complications.
7. Administer angiotensin-converting enzyme (ACE) inhibitors, angiotensin-II receptor blockers (ARBs), calcium channel blockers, aspirin, thienopyridines (clopidogrel), and lipid-lowering agents as prescribed.
8. Encourage the client to verbalize feelings regarding the MI.

I. Cardiac rehabilitation: Process of actively assisting the client with cardiac disease to achieve and maintain a vital and productive life within the limitations of the heart disease; also refer to section VII, D (Coronary Artery Disease, Interventions).

X. Heart Failure

A. Description

1. Heart failure is the inability of the heart to maintain adequate cardiac output to meet the metabolic needs of the body because of impaired pumping ability.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Diminished cardiac output results in inadequate peripheral tissue perfusion.
3. Congestion of the lungs and periphery may occur; the client can develop acute pulmonary edema.

B. Classification
1. Acute heart failure occurs suddenly.
2. Chronic heart failure develops over time; however, a client with chronic heart failure can develop an acute episode.

C. Types of heart failure
1. Right ventricular failure, left ventricular failure
   - **a.** Because the two ventricles of the heart represent two separate pumping systems, it is possible for one to fail alone for a short period.
   - **b.** Most heart failure begins with left ventricular failure and progresses to failure of both ventricles.
   - **c.** Acute pulmonary edema, a medical emergency, results from left ventricular failure.
   - **d.** If pulmonary edema is not treated, death will occur from suffocation because the client literally drowns in their own fluids.
2. Forward failure, backward failure
   - **a.** In forward failure, an inadequate output of the affected ventricle causes decreased perfusion to vital organs.
   - **b.** In backward failure, blood backs up behind the affected ventricle, causing increased pressure in the atrium behind the affected ventricle.
3. Low output, high output
   - **a.** In low-output failure, not enough cardiac output is available to meet the demands of the body.
   - **b.** High-output failure occurs when a condition causes the heart to work harder to meet the demands of the body.
4. Systolic failure, diastolic failure
   - **a.** Systolic failure, also known as heart failure with reduced ejection fraction (HFrEF), is a problem with contraction and ejection of blood.
   - **b.** Diastolic failure, also known as heart failure with preserved ejection fraction (HFpEF), is a problem with the heart relaxing and filling with blood.

D. Compensatory mechanisms
1. Compensatory mechanisms act to restore cardiac output, but they eventually have a damaging effect on pump action.
2. Compensatory mechanisms increase myocardial oxygen consumption; when myocardial reserve is exhausted, clinical manifestations of heart failure develop.
3. Compensatory mechanisms include increased heart rate and **stroke volume**, arterial vasoconstriction, sodium and water retention, and myocardial hypertrophy.

TABLE 53.2 Clinical Manifestations of Right-Sided and Left-Sided Heart Failure

Right-Sided Heart Failure	Left-Sided Heart Failure
Dependent edema (legs and sacrum)	Signs of pulmonary congestion
Jugular venous distention	Dyspnea
Abdominal distention	Tachypnea
Hepatomegaly	Crackles in the lungs
Splenomegaly	Dry, hacking cough
Anorexia and nausea	Paroxysmal nocturnal dyspnea
Weight gain	Increased BP (from fluid volume excess) or decreased BP (from pump failure)
Nocturnal diuresis	
Swelling of the fingers and hands	
Increased BP (from fluid volume excess) or decreased BP (from pump failure)	

BP, Blood pressure.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Elsevier. p. 671.

E. Assessment (Table 53.2)
1. Right- and left-sided heart failure
2. Acute pulmonary edema
   - **a.** Severe dyspnea
   - **b.** Tachycardia, tachypnea
   - **c.** Nasal flaring; use of accessory breathing muscles
   - **d.** Wheezing and crackles on auscultation; gurgling respirations
   - **e.** Expectoration of large amounts of blood-tinged, frothy sputum
   - **f.** Acute anxiety, apprehension, restlessness
   - **g.** Profuse sweating
   - **h.** Cold, clammy skin
   - **i.** Cyanosis

Signs of left ventricular failure are evident in the pulmonary system. Signs of right ventricular failure are evident in the systemic circulation.

F. Immediate management of acute pulmonary edema (see Clinical Judgment: Take Action Box)

G. Following the acute episode
1. Assist the client to identify precipitating risk factors of heart failure and methods of eliminating these risk factors.
2. Encourage the client to verbalize feelings about the lifestyle changes required as a result of the heart failure.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: TAKE ACTION

The nurse is monitoring a hospitalized client who is being treated for a diagnosis of heart failure. The client is on a cardiac monitor and oxygen at 2 L/minute via nasal cannula. The client calls the nurse and reports severe dyspnea. On assessment the nurse notes that the client's heart rate is 128 beats per minute and respirations are 24 breaths per minute. The client is anxious and restless, is sweating profusely, and the client's skin is cool and clammy. Wheezing and crackles are heard on auscultation of the lungs, and the client is expectorating blood-tinged frothy sputum. Pulse oximetry reading is 89%. The nurse takes the following actions:

- Places the client in a high-Fowler's position.
- Stays with the client and asks another person to contact the primary health care provider.
- Ensures oxygen administration and increases flow rate or method of administration as prescribed.
- Ensures that an intravenous (IV) access device is in place.
- Prepares for the administration of a diuretic and morphine sulfate.
- Inserts a Foley catheter as prescribed.
- Prepares for intubation and ventilator support, if required.
- Documents the event, actions taken, and the client's response.

3. Instruct the client in the prescribed medication regimen, which may include digoxin, a diuretic, ACE inhibitors, low-dose beta blockers, and vasodilators.
4. Advise the client to notify the PHCP if side effects occur from the medications.
5. Advise the client to avoid over-the-counter medications.
6. Instruct the client to contact the PHCP if unable to take medications because of illness.
7. Instruct the client to avoid large amounts of caffeine, found in coffee, tea, cocoa, chocolate, and some carbonated beverages.
8. Instruct the client about the prescribed low-sodium, low-fat, and low-cholesterol diet.
9. Provide the client with a list of potassium-rich foods, because diuretics (except for potassium-sparing diuretics) can cause hypokalemia.
10. Instruct the client regarding fluid restriction, if prescribed, advising the client to spread the fluid out during the day and to suck on hard candy to reduce thirst.
11. Instruct the client to balance periods of activity and rest.
12. Advise the client to avoid isometric activities, which increase pressure in the heart.
13. Instruct the client to monitor daily weight.
14. Instruct the client to report signs of fluid retention such as edema or weight gain.

XI. Cardiogenic Shock and Associated Invasive Monitoring (refer to Chapter 70)

XII. Inflammatory Diseases of the Heart

A. Pericarditis

1. Description
- **a.** Pericarditis is an acute or chronic inflammation of the pericardium.
- **b.** Chronic pericarditis, a chronic inflammatory thickening of the pericardium, constricts the heart, causing compression.
- **c.** The pericardial sac becomes inflamed.
- **d.** Pericarditis can result in loss of pericardial elasticity or an accumulation of fluid within the sac.
- **e.** Heart failure or cardiac tamponade may result.

2. Assessment
- **a.** Pain in the anterior chest that radiates to the left side of the neck, shoulder, or back
- **b.** Pain is grating and is aggravated by breathing (particularly inspiration), coughing, and swallowing.
- **c.** Pain is worse when in the supine position and may be relieved by leaning forward.
- **d.** Pericardial friction rub (scratchy, high-pitched sound) on auscultation is produced by the rubbing of the inflamed pericardial layers.
- **e.** Fever and chills
- **f.** Fatigue and malaise
- **g.** Elevated white blood cell count
- **h.** Electrocardiographic changes with acute pericarditis; ST-segment elevation with the onset of inflammation; atrial fibrillation is common.
- **i.** Signs of right ventricular failure in clients with chronic constrictive pericarditis

3. Interventions
- **a.** Assess the nature of the pain.
- **b.** Place the client in a high-Fowler's position, or upright and leaning forward.
- **c.** Administer oxygen.
- **d.** Administer analgesics, nonsteroidal antiinflammatory drugs (NSAIDs), or corticosteroids for pain as prescribed.
- **e.** Auscultate for a pericardial friction rub.
- **f.** Check results of blood culture to identify the causative organism.
- **g.** Administer antibiotics for bacterial infection as prescribed.
- **h.** Administer diuretics and digoxin as prescribed to the client with chronic constrictive pericarditis; surgical incision of the pericardium (pericardial window) or pericardiectomy may be necessary.
- **i.** Monitor for signs of cardiac tamponade.
- **j.** Notify the PHCP if signs of cardiac tamponade occur.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Myocarditis
1. Description: Acute or chronic inflammation of the myocardium as a result of pericarditis, systemic infection, or allergic response
2. Assessment
   - **a.** Fever
   - **b.** Dyspnea
   - **c.** Tachycardia
   - **d.** Chest pain
   - **e.** Pericardial friction rub
   - **f.** Gallop rhythm
   - **g.** Murmur
   - **h.** Pulsus alternans
   - **i.** Signs of heart failure
3. Interventions
   - **a.** Position for comfort, such as sitting up and leaning forward.
   - **b.** Administer oxygen as prescribed.
   - **c.** Administer analgesics, salicylates, and NSAIDs as prescribed to reduce fever and pain.
   - **d.** Administer digoxin as prescribed.
   - **e.** Administer antidysrhythmics as prescribed.
   - **f.** Administer antibiotics as prescribed to treat the causative organism.
   - **g.** Monitor for complications including thrombus, heart failure, and cardiomyopathy.

C. Endocarditis
1. Description
   - **a.** Endocarditis is an inflammation of the inner lining of the heart and valves.
   - **b.** Occurs primarily in clients who are IV drug users, have had valve replacements or repair of valves with prosthetic materials, or have other structural cardiac defects
   - **c.** Ports of entry for the infecting organism include the oral cavity (especially if the client has had a dental procedure in the previous 3 to 6 months), infections (cutaneous, genitourinary, gastrointestinal, and systemic), and surgery or invasive procedures, including IV line placement.
2. Assessment
   - **a.** Fever
   - **b.** Anorexia, weight loss
   - **c.** Fatigue
   - **d.** Cardiac murmurs
   - **e.** Heart failure
   - **f.** Embolic complications from vegetation fragments traveling through the arterial circulation
   - **g.** Petechiae
   - **h.** Splinter hemorrhages in the nail beds
   - **i.** Osler's nodes (reddish, tender lesions) on the pads of the fingers, hands, and toes
   - **j.** Janeway lesions (nontender hemorrhagic lesions) on the fingers, toes, nose, or earlobes
   - **k.** Splenomegaly
   - **l.** Clubbing of the fingers
3. Interventions
   - **a.** Provide adequate rest balanced with activity to prevent thrombus formation.
   - **b.** Monitor for signs of heart failure.
   - **c.** Monitor for splenic emboli, as evidenced by sudden abdominal pain radiating to the left shoulder and rebound abdominal tenderness on palpation.
   - **d.** Monitor for renal emboli, as evidenced by flank pain radiating to the groin, hematuria, and pyuria.
   - **e.** Monitor for confusion, aphasia, or dysphasia, which may indicate central nervous system emboli.
   - **f.** Monitor for pulmonary emboli as evidenced by pleuritic chest pain, dyspnea, and cough.
   - **g.** Assess skin, mucous membranes, and conjunctiva for petechiae.
   - **h.** Assess nail beds for splinter hemorrhages.
   - **i.** Assess for Osler's nodes on the pads of the fingers, hands, and toes.
   - **j.** Assess for Janeway lesions on the fingers, toes, nose, or earlobes.
   - **k.** Assess for clubbing of the fingers.
   - **l.** Evaluate blood culture results.
   - **m.** Administer antibiotics intravenously as prescribed.
   - **n.** Plan and arrange for discharge, providing resources required for the continued administration of IV antibiotics.
4. Client education (Box 53.7)

XIII. Cardiac Tamponade (see Clinical Judgment: Evaluate Outcomes Box)

A. Description
1. A pericardial effusion occurs when the space between the parietal and visceral layers of the pericardium fills with fluid.
2. Pericardial effusion places the client at risk for cardiac tamponade, an accumulation of fluid in the pericardial cavity.
3. Tamponade restricts ventricular filling, and cardiac output drops.

⚠ Acute cardiac tamponade can occur when small volumes (20 to 50 mL) of fluid accumulate rapidly in the pericardium.

B. Assessment
1. Pulsus paradoxus
2. Increased CVP
3. Jugular venous distention with clear lungs
4. Distant, muffled heart sounds
5. Decreased cardiac output
6. Narrowing **pulse pressure**

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 53.7 Home Care Instructions for the Client with Infective Endocarditis

- Teach the client to maintain aseptic technique during set-up and administration of intravenous (IV) antibiotics.
- Instruct the client to administer IV antibiotics at scheduled times to maintain the blood level.
- Instruct the client to monitor IV catheter sites and report signs of infection immediately to the PHCP or cardiologist.
- Instruct the client to record the temperature daily for up to 6 weeks and to report fever.
- Encourage oral hygiene at least twice a day with a soft toothbrush and thorough rinsing.
- Teach the client to cleanse any skin lacerations thoroughly and apply an antibiotic ointment as prescribed.
- Client should inform all PHCPs of history of endocarditis and ask about the use of prophylactic antibiotics prior to invasive respiratory procedures and dentistry.
- Teach the client to observe for signs and symptoms of embolic conditions and heart failure.

TABLE 53.3 Aortic Valve Disorders

Aortic Stenosis	Aortic Insufficiency
Symptoms	
Dyspnea on exertion	Dyspnea
Angina	Angina
Syncope on exertion	Tachycardia
Fatigue	Fatigue
Orthopnea	Orthopnea
Paroxysmal nocturnal dyspnea	Paroxysmal nocturnal dyspnea
Harsh systolic crescendo-decrescendo murmur	Blowing decrescendo diastolic murmur
Interventions	
Refer to the section on repair procedures.	
Prepare the client for valve replacement as indicated.	

Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology*. (7th ed.). St. Louis: Elsevier. pp. 614, 644.

C. Interventions
   1. The client needs to be placed in a critical care unit for hemodynamic monitoring.
   2. Administer fluids intravenously as prescribed to manage decreased cardiac output.
   3. Prepare the client for chest x-ray or echocardiography.
   4. Prepare the client for pericardiocentesis to withdraw pericardial fluid if prescribed.
   5. Monitor for recurrence of tamponade following pericardiocentesis.
   6. If the client experiences recurrent tamponade or recurrent effusions or develops adhesions from chronic pericarditis, a portion (pericardial window) or all of the pericardium (pericardiectomy) may be removed to allow adequate ventricular filling and contraction.

CLINICAL JUDGMENT: EVALUATE OUTCOMES

The nurse is evaluating the condition of a client after pericardiocentesis performed to treat cardiac tamponade. The nurse determines that the procedure was effective when noting the following, when comparing preprocedure and postprocedure assessment findings.

- Clear breath sounds
- Increased blood pressure
- Normal jugular veins
- Decreased central venous pressure
- Signs of increased cardiac output (blood pressure and pulse rate and rhythm normal for the client, strong peripheral pulses; no chest pain, dyspnea, or syncope)

XIV. Valvular Heart Disease

A. Description
   1. Valvular heart disease occurs when the heart valves cannot open fully (stenosis) or close completely (insufficiency or regurgitation).
   2. Valvular heart disease prevents efficient blood flow through the heart.

B. Types
   1. Mitral stenosis: Valvular tissue thickens and narrows the valve opening, preventing blood from flowing from the left atrium to the left ventricle.
   2. Mitral insufficiency, regurgitation: Valve is incompetent, preventing complete valve closure during systole.
   3. Mitral valve prolapse: Valve leaflets protrude into the left atrium during **systole.**
   4. Aortic stenosis: Valvular tissue thickens and narrows the valve opening, preventing blood from flowing from the left ventricle into the aorta.
   5. Aortic insufficiency: Valve is incompetent, preventing complete valve closure during **diastole.**
   6. For aortic disorders, see Table 53.3.
   7. For tricuspid disorders, see Table 53.4.
   8. For pulmonary valve disorders, see Table 53.5.

C. Repair procedures
   1. Percutaneous balloon valvuloplasty
      a. A balloon catheter is passed from the femoral vein through the atrial septum to the mitral valve or through the femoral artery to the aortic valve.
      b. The balloon is inflated to enlarge the orifice.
      c. Monitor for bleeding from the catheter insertion site.

TABLE 53.4 Tricuspid Valve Disorders

Tricuspid Stenosis	Tricuspid Insufficiency
Symptoms	
Easily fatigued with minimal effort	Asymptomatic in mild situations
Reports fluttering sensations in the neck (obstructed venous flow)	Signs of right ventricular failure, including ascites, hepatomegaly, peripheral edema
Cyanosis	Pleural effusion
Rumbling diastolic murmur	Systolic murmur heard at the left sternal border, fourth intercostal space
Signs of right ventricular failure, including ascites, hepatomegaly, peripheral edema, jugular vein distention with clear lung fields	
Symptoms of decreased cardiac output	
Interventions	
Refer to the section on repair procedures.	
Prepare the client for valve replacement as indicated.	

Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology*. (7th ed.). St. Louis: Elsevier. p. 565; Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Elsevier. p. 613.

TABLE 53.5 Pulmonary Valve Disorders

Pulmonary Stenosis	Pulmonary Insufficiency
Symptoms	
Asymptomatic in a mild condition	Asymptomatic in mild condition
Dyspnea	Dyspnea
Fatigue	Fatigue
Syncope	Syncope
Signs of right ventricular failure, including ascites, hepatomegaly, peripheral edema	Signs of right ventricular failure, including ascites, hepatomegaly, peripheral edema
Systolic thrill heard at left sternal border	Systolic thrill heard at left sternal border
Interventions	
Refer to the section on repair procedures.	Refer to the section on repair procedures.
Prepare the client for pulmonary valve commissurotomy as indicated.	Prepare the client for pulmonary valve replacement as indicated.

Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology*. (7th ed.). St. Louis: Elsevier. p. 645.

d. Institute precautions for arterial puncture if appropriate; site care and monitoring is similar to that after cardiac catheterization.
e. Monitor for signs of systemic emboli.
f. Monitor for signs of a regurgitant valve by monitoring cardiac rhythm, heart sounds, and cardiac output.

2. Mitral annuloplasty: Tightening and suturing the malfunctioning valve annulus to eliminate or greatly reduce regurgitation; percutaneous or open surgical approach
3. Commissurotomy, valvotomy
a. Thrombi are removed and calcium deposits are debrided; the valve is incised and widened.
b. Percutaneous route or open heart surgical approach

D. Valve replacement procedures
1. Mechanical prosthetic valves are durable.
2. Risk of clot formation is high as the body reacts to the artificial materials; anticoagulation is required.

⚠ Thromboembolism can be a complication following valve replacement with a mechanical prosthetic valve, and lifetime anticoagulant therapy is required.

3. Bioprosthetic valves
a. Biological grafts are xenografts (valves from other species, such as porcine valves [pig] or bovine valves [cow]) or homografts (from human cadavers). These valves are less durable than mechanical prosthetic valves.
b. The risk of clot formation is small; therefore, long-term anticoagulation may not be indicated.
4. Open heart surgical approach
5. Preoperative interventions: Consult with the PHCP regarding discontinuing anticoagulants 72 hours before surgery.
6. Postoperative interventions
a. Monitor closely for signs of bleeding.
b. Monitor cardiac output and for signs of heart failure.
c. Client education (Box 53.8)

XV. Cardiomyopathy (Table 53.6)

A. Description
1. Cardiomyopathy is a subacute or chronic disorder of the heart muscle.
2. Treatment is palliative, not curative, and the client needs to deal with numerous lifestyle changes and a shortened life span.

B. Types, signs and symptoms, and treatment (see Table 53.6)

XVI. Vascular Disorders

A. Venous thrombosis
1. Description
a. Thrombus can be associated with an inflammatory process.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 53.8 Client Instructions Following Valve Replacement

- Adequate rest is important; fatigue is common.
- Anticoagulant therapy is necessary if a mechanical prosthetic valve has been inserted.
- Instruct the client concerning hazards related to anticoagulant therapy and to notify the PHCP or cardiologist of any bleeding or excessive bruising.
- Monitor incision and report any drainage or redness.
- Instruct the client concerning the importance of good oral hygiene to reduce the risk of infective endocarditis.
- Brush teeth twice daily with a soft toothbrush, followed by oral rinses.
- Avoid irrigation devices, electric toothbrushes, and flossing, because these activities can cause the gums to bleed, allowing bacteria to enter the mucous membranes and bloodstream.
- Avoid any dental procedures for 6 months.
- Avoid heavy lifting (more than 10 lb [4.5 kg] or as prescribed), and exercise caution when in an automobile to prevent injury to the sternal incision.
- If a mechanical valve was inserted, a soft, audible clicking sound may be heard.
- Instruct the client concerning the importance of prophylactic antibiotics before any invasive procedure and the importance of informing all PHCPs of history of valve replacement or repair.
- Obtain and wear a MedicAlert bracelet.

b. When a thrombus develops, inflammation occurs, thickening the vein wall and leading to embolization.

2. Types
- **a.** Thrombophlebitis: Thrombus associated with vein inflammation
- **b.** Phlebothrombosis: Thrombus without vein inflammation
- **c.** Phlebitis: Vein inflammation associated with invasive procedures, such as IV lines
- **d.** Deep vein thrombophlebitis: More serious than a superficial thrombophlebitis because of the risk for pulmonary embolism

3. Risk factors for thrombus formation
- **a.** Venous stasis from varicose veins, heart failure, immobility
- **b.** Hypercoagulability disorders
- **c.** Injury to the venous wall from IV injections; administration of vessel irritants (chemotherapy, hypertonic solutions)
- **d.** Following surgery, particularly orthopedic and abdominal surgery
- **e.** Pregnancy
- **f.** Ulcerative colitis
- **g.** Use of oral contraceptives
- **h.** Certain malignancies
- **i.** Fractures or other injuries of the pelvis or lower extremities

B. Phlebitis

1. Assessment
- **a.** Red, warm area radiating up the vein and extremity
- **b.** Pain
- **c.** Swelling

2. Interventions
- **a.** Apply warm, moist soaks as prescribed to dilate the vein and promote circulation (assess temperature of soak before applying).
- **b.** Assess for signs of complications such as tissue necrosis, infection, or pulmonary embolus.

C. Deep vein thrombophlebitis

1. Assessment
- **a.** Calf or groin tenderness or pain with or without swelling
- **b.** Positive Homans' sign may be noted; however, false-positive results are common, so this is not a reliable assessment measure.
- **c.** Warm skin that is tender to touch

2. Interventions
- **a.** Provide bed rest if prescribed.
- **b.** Elevate the affected extremity above the level of the heart as prescribed.
- **c.** Avoid using the knee gatch or a pillow under the knees.
- **d.** Do not massage the extremity.
- **e.** Provide thigh-high or knee-high antiembolism stockings as prescribed to reduce venous stasis and assist in the venous return of blood to the heart; teach how to apply and remove stockings.
- **f.** Administer intermittent or continuous warm, moist compresses as prescribed.
- **g.** Palpate the site gently, monitoring for warmth and edema.
- **h.** Measure and record the circumferences of the thighs and calves.
- **i.** Monitor for shortness of breath and chest pain, which can indicate pulmonary emboli.
- **j.** Administer thrombolytic therapy (tissue plasminogen activator) if prescribed, which must be initiated within 5 days after the onset of symptoms.
- **k.** Administer heparin therapy as prescribed to prevent enlargement of the existing clot and prevent the formation of new clots.
- **l.** Monitor activated partial thromboplastin time during heparin therapy.
- **m.** Administer warfarin as prescribed following heparin therapy when the symptoms of deep vein thrombophlebitis have resolved.
- **n.** Monitor prothrombin time and international normalized ratio during warfarin therapy.
- **o.** Monitor for the adverse effects associated with anticoagulant therapy.
- **p.** Client education (Box 53.9)

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

TABLE 53.6 Pathophysiology, Signs and Symptoms, and Treatment of Cardiomyopathies

	Hypertrophic Cardiomyopathy		
Dilated Cardiomyopathy	**Nonobstructed**	**Obstructed**	**Restrictive Cardiomyopathy**
Pathophysiology			
▪ Fibrosis of myocardium and endocardium ▪ Dilated chambers ▪ Mural wall thrombi prevalent	▪ Hypertrophy of the walls ▪ Hypertrophied septum ▪ Relatively small chamber size	▪ Same as for nonobstructed except for obstruction of left ventricular outflow tract associated with the hypertrophied septum and mitral valve incompetence	▪ Mimics constrictive pericarditis ▪ Fibrosed walls cannot expand or contract ▪ Chambers narrowed; emboli common
			Signs and Symptoms			
▪ Fatigue and weakness ▪ Heart failure (left side) ▪ Dysrhythmias or heart block ▪ Systemic or pulmonary emboli ▪ S_3 and S_4 gallops ▪ Moderate to severe cardiomegaly	▪ Dyspnea ▪ Angina ▪ Fatigue, syncope, palpitations ▪ Mild cardiomegaly ▪ S_4 gallop ▪ Ventricular dysrhythmias ▪ Sudden death common ▪ Heart failure	▪ Same as for nonobstructed except with mitral regurgitation murmur ▪ Atrial fibrillation	▪ Dyspnea and fatigue ▪ Heart failure (right side) ▪ Mild to moderate cardiomegaly ▪ S_3 and S_4 gallops ▪ Heart block ▪ Emboli
Treatment			
▪ Symptomatic treatment of heart failure ▪ Vasodilators ▪ Control of dysrhythmias ▪ Surgery: Heart transplant	For both nonobstructed and obstructed: ▪ Symptomatic treatment ▪ Beta blockers ▪ Conversion of atrial fibrillation ▪ Surgery: Ventriculomyotomy or muscle resection with mitral valve replacement ▪ Digoxin, nitrates, and other vasodilators contraindicated with the obstructed form		▪ Supportive treatment of symptoms ▪ Treatment of hypertension ▪ Conversion from dysrhythmias ▪ Exercise restrictions ▪ Emergency treatment of acute pulmonary edema

Adapted from Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Elsevier. p. 692.

BOX 53.9 Instructions for the Client with Deep Vein Thrombophlebitis

- Instruct the client concerning the hazards of anticoagulation therapy.
- Recognize the signs and symptoms of bleeding.
- Avoid prolonged sitting or standing, constrictive clothing, or crossing the legs when seated.
- Elevate the legs for 10 to 20 minutes every few hours each day.
- Plan a progressive walking program.
- Inspect the legs for edema, and measure the circumference of the legs.
- Wear antiembolism stockings as prescribed.
- Avoid smoking.
- Avoid any medications unless prescribed by the PHCP or cardiologist.
- Instruct the client concerning the importance of follow-up PHCP visits and laboratory studies.
- Obtain and wear a MedicAlert bracelet.

D. Venous insufficiency

1. Description

a. Venous insufficiency results from prolonged venous hypertension, which stretches the veins and damages the valves.

b. The resultant edema and venous stasis cause venous stasis ulcers, swelling, and cellulitis.

c. Treatment focuses on decreasing edema and promoting venous return from the affected extremity.

d. Treatment for venous stasis ulcers focuses on healing the ulcer and preventing stasis and ulcer recurrence.

2. Assessment

a. Stasis dermatitis or brown discoloration along the ankles and lower calf

b. Edema

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

c. Ulcer formation: Edges are uneven, ulcer bed is pink, and granulation is present; usually located on the lateral malleolus.

3. Interventions

⚠ For venous insufficiency, leg elevation is usually prescribed to assist with the return of blood to the heart.

a. Instruct the client to wear elastic or compression stockings during the day and evening if prescribed (instruct the client to put on elastic stockings on awakening, before getting out of bed); stockings may be necessary for the remainder of the client's life.

b. Instruct the client to avoid prolonged sitting or standing, constrictive clothing, or crossing the legs when seated.

c. Instruct the client to elevate the legs above the level of the heart for 10 to 20 minutes every few hours each day.

d. Instruct the client in the use of an intermittent sequential pneumatic compression system, if prescribed (used twice daily for 1 hour in the morning and evening).

e. Advise the client with an open ulcer to apply the compression system over a dressing.

4. Wound care

a. Provide care to the wound as prescribed.

b. Assess the client's ability to care for the wound, and initiate home care resources as necessary.

c. If an Unna boot (dressing constructed of gauze moistened with zinc oxide) is prescribed, the PHCP will change it weekly.

d. The wound is cleansed with normal saline before application of the Unna boot; povidone-iodine and hydrogen peroxide are not used, because they destroy granulation tissue.

e. The Unna boot is covered with an elastic wrap that hardens to promote venous return and prevent stasis.

f. Monitor for signs of arterial occlusion from an Unna boot that may be too tight.

g. Keep tape off the client's skin.

h. Occlusive dressings such as polyethylene film or a hydrocolloid dressing may be used to cover the ulcer.

5. Medications

a. Apply topical agents to the wound as prescribed to debride the ulcer, eliminate necrotic tissue, and promote healing.

b. When applying topical debriding agents, apply an oil-based agent such as petroleum jelly on surrounding skin to protect healthy tissue.

c. Administer antibiotics as prescribed if infection or cellulitis occurs.

E. Varicose veins

1. Description

a. Distended, protruding veins that appear darkened and tortuous.

b. Vein walls weaken and dilate, and valves become incompetent.

2. Assessment

a. Pain in the legs with dull aching after standing

b. A feeling of fullness in the legs

c. Ankle edema

3. Trendelenburg's test

a. Place the client in a supine position with the legs elevated.

b. When the client sits up, if varicosities are present, veins fill from the proximal end; veins normally fill from the distal end.

4. Interventions

a. Emphasize wearing antiembolism stockings as prescribed.

b. Instruct the client to elevate the legs as much as possible.

c. Instruct the client to avoid constrictive clothing and pressure on the legs.

d. Prepare the client for sclerotherapy or vein stripping as prescribed.

5. Sclerotherapy

a. A solution is injected into the vein, followed by the application of a pressure dressing.

b. Incision and drainage of the trapped blood in the sclerosed vein is performed 14 to 21 days after the injection, followed by the application of a pressure dressing for 12 to 18 hours.

6. Laser therapy: A laser fiber is used to heat and close the main vessel contributing to the varicosity.

7. Vein stripping: Varicose veins may be removed if they are larger than 4 mm in diameter or if they are in clusters; other treatments are usually tried before vein stripping.

XVII. Arterial Disorders

A. Peripheral arterial disease

1. Description

a. Chronic disorder in which partial or total arterial occlusion deprives the lower extremities of oxygen and nutrients

b. Tissue damage occurs below the level of the arterial occlusion.

c. Atherosclerosis is the most common cause of peripheral arterial disease.

2. Assessment

a. Intermittent claudication (pain in the muscles during exercise, resulting from an inadequate blood supply)

b. Rest pain, characterized by numbness, burning, or aching in the distal portion of the lower extremities, which awakens the client

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

at night and is relieved by placing the extremity in a dependent position
- **c.** Lower back or buttock discomfort
- **d.** Dry, scaly skin and loss of hair on the legs
- **e.** Thickened toenails
- **f.** Cold and gray-blue color of skin in the lower extremities
- **g.** Elevational pallor and dependent rubor in the lower extremities
- **h.** Decreased or absent peripheral pulses
- **i.** Painful arterial ulcer formation on or between the toes or on the upper aspect of the foot
- **j.** BP measurements at the thigh, calf, and ankle are lower than the brachial pressure (normally, BP readings in the thigh and calf are higher than those in the upper extremities).

3. Interventions

Because swelling in the extremities prevents arterial blood flow, the client with peripheral arterial disease is instructed to elevate the feet at rest but to refrain from elevating them above the level of the heart, because extreme elevation slows arterial blood flow to the feet. In severe cases of peripheral arterial disease, clients with edema may sleep with the affected limb hanging from the bed, or they may sit upright (without leg elevation) in a chair for comfort.

- **a.** Assess pain.
- **b.** Monitor the extremities for color, motion and sensation, and pulses.
- **c.** Obtain distal extremity BP measurements.
- **d.** Assess for signs of ulcer formation or signs of gangrene.
- **e.** Assist in developing an individualized exercise program, which is increased slowly to improve arterial flow through the development of collateral circulation.
- **f.** Instruct the client to walk to the point of claudication pain, stop and rest, and then walk a little farther.
- **g.** Instruct the client with peripheral arterial disease to avoid crossing the legs, which interferes with blood flow.
- **h.** Instruct the client to avoid exposing extremities to cold (causes vasoconstriction) and to wear socks or insulated shoes for warmth at all times.
- **i.** Instruct the client never to apply direct heat to the limb, such as with a heating pad or hot water, because the decreased sensitivity in the limb can cause burns.
- **j.** Instruct the client to inspect the skin on the extremities daily and to report any signs of skin breakdown.
- **k.** Instruct the client to avoid tobacco and caffeine because of their vasoconstrictive effects.
- **l.** Instruct the client in the use of hemorheological and antiplatelet medications as prescribed.

4. Procedures to improve arterial blood flow
   - **a.** Percutaneous transluminal angioplasty, with or without intravascular stent
   - **b.** Laser-assisted angioplasty
   - **c.** Atherectomy
   - **d.** Peripheral arterial bypass surgery: Graft material is sutured above and below the occlusion to facilitate blood flow around the occlusion. Inflow procedures bypass the occlusion above the superficial femoral arteries and include aortoiliac, aortofemoral, and axillofemoral bypasses; outflow procedures bypass the occlusion at or below the superficial femoral arteries and include femoropopliteal and femorotibial bypass (Fig. 53.12).
5. Preoperative interventions
   - **a.** Assess baseline vital signs and peripheral pulses.
   - **b.** Insert an IV line and urinary catheter as prescribed.
   - **c.** Maintain a central venous catheter and/or arterial line if inserted.
6. Postoperative interventions
   - **a.** Assess vital signs and notify the PHCP if changes occur.
   - **b.** Monitor for hypotension, which may indicate hypovolemia.
   - **c.** Monitor for hypertension, which may place stress on the graft and cause clot formation.

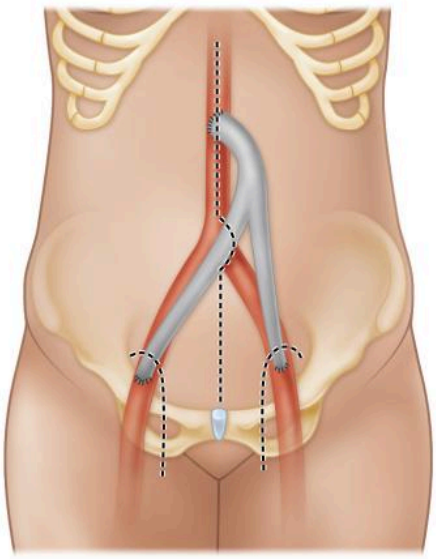

FIG. 53.12 In aortoiliac and aortofemoral bypass surgery, a midline incision into the abdominal cavity is required, with an additional incision in each groin.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

d. Maintain bed rest for 24 hours as prescribed.
e. Instruct the client to keep the affected extremity straight, limit movement, and avoid bending the knee and hip.
f. Monitor for warmth, redness, and edema, which often are expected outcomes because of increased blood flow.
g. Monitor for vessel or graft occlusion, which often occurs within the first 24 hours.
h. Assess peripheral pulses and assess for adverse changes in color and temperature of the extremity.
i. Assess the incision for drainage, warmth, or swelling.
j. Monitor for excessive bleeding (a small amount of bloody drainage is expected).
k. Monitor the area over the graft for hardness, tenderness, and warmth, which may indicate infection; if this occurs, notify the PHCP immediately.
l. Instruct the client about proper foot care and measures to prevent ulcer formation.
m. Assist the client in modifying lifestyle to prevent further plaque formation.
n. Following arterial revascularization, monitor for a sharp increase in pain, because pain is frequently the first indicator of postoperative graft occlusion. If signs of graft occlusion occur, notify the PHCP immediately.

B. Raynaud's disease
1. Description
a. Raynaud's disease is vasospasm of the arterioles and arteries of the upper and lower extremities.
b. Vasospasm causes constriction of the cutaneous vessels.
c. Attacks occur with exposure to cold or stress.
d. Affects primarily fingers, toes, ears, and cheeks
2. Assessment
a. Blanching of the extremity, followed by cyanosis from vasoconstriction
b. Reddened tissue when the vasospasm is relieved
c. Numbness, tingling, swelling, and a cold temperature at the affected body part
3. Interventions
a. Monitor pulses.
b. Administer vasodilators as prescribed.
c. Instruct the client regarding medication therapy.
d. Assist the client to identify and avoid precipitating factors such as cold and stress.
e. Instruct the client to avoid smoking.
f. Instruct the client to wear warm clothing, socks, and gloves in cold weather.
g. Advise the client to avoid injuries to fingers and hands.

C. Buerger's disease (thromboangiitis obliterans)
1. Description
a. Buerger's disease is an occlusive disease of the median and small arteries and veins.
b. The distal upper and lower limbs are affected most commonly.
2. Assessment
a. Intermittent claudication
b. Ischemic pain occurring in the digits while at rest
c. Aching pain that is more severe at night
d. Cool, numb, or tingling sensation
e. Diminished pulses in the distal extremities
f. Extremities that are cool and red in the dependent position
g. Development of ulcerations in the extremities
3. Interventions: See Raynaud's disease

XVIII. Aortic Aneurysms

A. Description
1. An aortic aneurysm is an abnormal dilation of the arterial wall caused by localized weakness and stretching in the medial layer or wall of the aorta.
2. The aneurysm can be located anywhere along the abdominal aorta.
3. The goal of treatment is to limit the progression of the disease by modifying risk factors, controlling the BP to prevent strain on the aneurysm, recognizing symptoms early, and preventing rupture.

B. Types of aortic aneurysm
1. Fusiform: Diffuse dilation that involves the entire circumference of the arterial segment
2. Saccular: Distinct localized outpouching of the artery wall
3. Dissecting: Created when blood separates the layers of the artery wall, forming a cavity between them
4. False (pseudoaneurysm): Occurs when the clot and connective tissue are outside the arterial wall as a result of vessel injury or trauma to all three layers of the arterial wall.

C. Assessment
1. Thoracic aneurysm
a. Pain extending to neck, shoulders, lower back, or abdomen
b. Syncope
c. Dyspnea
d. Increased pulse
e. Cyanosis
f. Hoarseness, difficulty swallowing because of pressure from the aneurysm

Telegram & Insta: NCLEX_RN_Edu

2. Abdominal aneurysm
   a. Prominent, pulsating abdominal mass at or above the umbilicus
   b. Systolic bruit over the aorta
   c. Abdominal distention
   d. Tenderness on deep palpation
   e. Abdominal or lower back pain
3. Rupturing aneurysm
   a. Severe abdominal or back pain
   b. Lumbar pain radiating to the flank and groin
   c. Hypotension
   d. Increased pulse rate
   e. Signs of shock
   f. Hematoma at flank area
4. Diagnostic tests
   a. Diagnostic tests are done to confirm the presence, size, and location of the aneurysm.
   b. Tests include abdominal ultrasound, computed tomography scan, and arteriography.
5. Interventions
   a. Monitor vital signs.
   b. Assess for back or abdominal pain.
   c. Question the client regarding the sensation of pulsation in the abdomen.
   d. Avoid palpating the abdomen if an abdominal aneurysm is suspected.
   e. Check peripheral circulation, including pulses, temperature, and color.
   f. Observe for signs of rupture (back pain, abdominal pain, changes in vital signs, signs of shock).
6. Nonsurgical interventions
   a. Modify risk factors.
   b. Instruct the client regarding the procedure for monitoring BP.
   c. Instruct the client on the importance of regular PHCP visits to monitor the size of the aneurysm.
   d. Instruct the client to notify the PHCP immediately if they experience severe back or abdominal pain or fullness, soreness over the umbilicus, sudden development of discoloration in the extremities, or a persistent elevation of BP.

Instruct the client with an aortic aneurysm to report immediately the occurrence of chest or back pain, shortness of breath, difficulty swallowing, or hoarseness.

D. Pharmacological interventions
   1. Administer antihypertensives to maintain the BP within normal limits and to prevent strain on the aneurysm.
   2. Instruct the client about the purpose, side effects, and schedule of the medications.

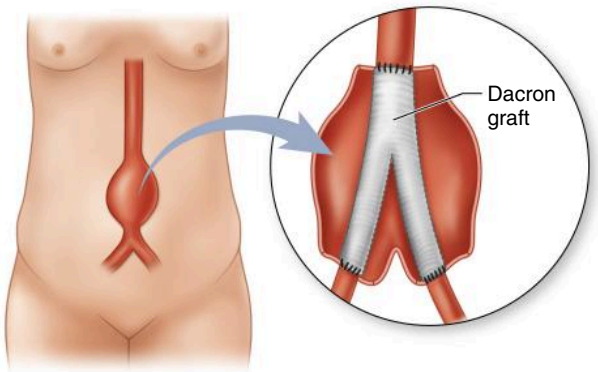

FIG. 53.13 Surgical repair of an abdominal aortic aneurysm with a woven Dacron graft.

E. Abdominal aortic aneurysm resection
   1. Description: Surgical resection or excision of the aneurysm; the excised section is replaced with a graft that is sewn end to end (Fig. 53.13).
   2. Preoperative interventions
      a. Assess all peripheral pulses as a baseline for postoperative comparison.
      b. Instruct the client in coughing and deep-breathing exercises.
   3. Postoperative interventions
      a. Monitor vital signs.
      b. Monitor peripheral pulses distal to the graft site.
      c. Monitor for signs of graft occlusion, including changes in pulses, cool to cold extremities below the graft, white or blue extremities or flanks, severe pain, or abdominal distention.
      d. Limit elevation of the head of the bed to 45 degrees to prevent flexion of the graft.
      e. Maintain nasogastric tube to low suction until bowel sounds return; monitor for bowel sounds.
      f. Monitor for hypovolemia and kidney failure resulting from significant blood loss during surgery.
      g. Monitor urine output hourly, and notify the PHCP if it is lower than 30 to 50 mL/hr.
      h. Monitor serum creatinine and blood urea nitrogen levels daily.
      i. Monitor respiratory status, and auscultate breath sounds to identify respiratory complications.
      j. Encourage turning, coughing and deep breathing, and splinting the incision.
      k. Monitor incision site for bleeding and signs of infection.
      l. Monitor pain level, and administer pain medication as prescribed.
      m. Ambulate as prescribed.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

n. Prepare the client for discharge by providing instructions regarding pain management, wound care, and activity restrictions.
o. Instruct the client not to lift objects heavier than 15 to 20 lb for 6 to 12 weeks.
p. Advise the client to avoid activities requiring pushing, pulling, or straining.
q. Instruct the client not to drive a vehicle until approved by the PHCP.
r. Endovascular aneurysm grafting involves insertion of a graft using a vascular catheter; it does not require an abdominal incision. The preoperative and postoperative care is similar to that of a surgical abdominal aneurysm repair.

F. Thoracic aneurysm repair
1. Description
a. A thoracotomy or median sternotomy approach is used to enter the thoracic cavity.
b. The aneurysm is exposed and excised, and a graft or prosthesis is sewn onto the aorta.
c. Total cardiopulmonary bypass is necessary for excision of aneurysms in the ascending aorta.
d. Partial cardiopulmonary bypass is used for clients with an aneurysm in the descending aorta.
2. Postoperative interventions
a. Monitor vital signs and neurological and renal status.
b. Monitor for signs of hemorrhage, such as a drop in BP and increased pulse rate and respirations, and report them to the PHCP immediately.
c. Monitor chest tubes for an increase in chest drainage, which may indicate bleeding or separation at the graft site.
d. Assess sensation and motion of all extremities and notify the PHCP if deficits are noted, which can occur because of a lack of blood supply to the spinal cord during surgery.
e. Monitor respiratory status and auscultate breath sounds to identify respiratory complications.
f. Encourage turning, coughing, and deep breathing while splinting the incision.
g. Prepare the client for discharge by providing instructions regarding pain management, wound care, and activity restrictions.
h. Instruct the client not to lift objects heavier than 15 lb for 6 to 12 weeks.
i. Advise the client to avoid activities requiring pushing, pulling, or straining.
j. Instruct the client not to drive a vehicle until approved by the PHCP.

XIX. Embolectomy

A. Description
1. Embolectomy is removal of an embolus from an artery, using a catheter.
2. A patch graft may be required to close the artery.

B. Preoperative interventions
1. Obtain a baseline assessment of peripheral pulses.
2. Administer anticoagulants as prescribed.
3. Administer thrombolytics as prescribed.
4. Place a bed cradle on the bed to keep the weight of linens from causing pain and pressure.
5. Avoid bumping or jarring the bed.
6. Maintain the extremity in a slightly dependent position.

C. Postoperative interventions
1. Assess cardiac, respiratory, and neurological status.
2. Monitor affected extremity for color, temperature, and pulse.
3. Assess sensory and motor function of the affected extremity.
4. Monitor for signs and symptoms of new thrombi or emboli.
5. Administer oxygen as prescribed.
6. Monitor pulse oximetry.
7. Monitor for complications caused by reperfusion of the artery, such as spasms and swelling of the skeletal muscles.
8. Monitor for signs of swollen skeletal muscles such as edema, pain on passive movement, poor capillary refill, numbness, and muscle tenseness.
9. Maintain bed rest initially, with the client in a semi-Fowler's position.
10. Place a bed cradle on the bed.
11. Check the incision site for bleeding or hematoma.
12. Administer anticoagulants as prescribed.
13. Monitor laboratory values related to anticoagulant therapy.
14. Instruct the client to recognize the signs and symptoms of infection and edema.
15. Instruct the client to avoid prolonged sitting or crossing the legs when sitting.
16. Instruct the client to elevate the legs when sitting.
17. Instruct the client to wear antiembolism stockings as prescribed and how to remove and reapply the stockings.
18. Instruct the client to ambulate daily.
19. Instruct the client about anticoagulant therapy and the hazards associated with anticoagulants.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

XX. Vena Cava Filter

A. Vena cava filter: Insertion of an intracaval filter (umbrella) that partially occludes the inferior vena cava and traps emboli to prevent pulmonary emboli (Fig. 53.14)

B. The filter is placed through a catheter placed in a large vein in the neck or groin and advanced to the inferior vena cava.

C. Preoperative interventions: If the client has been taking an anticoagulant, consult with the PHCP regarding discontinuation of the medication preoperatively to prevent hemorrhage.

D. Postoperative interventions: Similar to care after embolectomy.

XXI. Hypertension

A. Description

1. For an adult (ages 18 years and older), a normal BP is a systolic BP below 120 mm Hg and a diastolic pressure below 80 mm Hg.
2. Elevated blood pressure is defined as a systolic BP between 120 and 129 mm Hg and a diastolic BP below 80 mm Hg.
3. Hypertension (Stage 1) is defined as an SBP between 130 and 139 mm Hg or a diastolic BP between 80 and 89 mm Hg.
4. Hypertension (Stage 2) is defined as a SBP at least 140 mm Hg or a diastolic BP at least 90 mm Hg.
5. If either the SBP or DBP is outside of a range, the higher measurement determines the classification.
6. Hypertension is a major risk factor for coronary, cerebral, renal, and peripheral vascular disease.
7. The disease is initially asymptomatic.
8. The goals of treatment include reduction of the BP and preventing or lessening the extent of organ damage.
9. Nonpharmacological approaches, such as lifestyle changes, may be prescribed initially; if the BP cannot be decreased after 1 to 3 months, the client may require pharmacological treatment.

B. Primary or essential hypertension

1. Risk factors
   - **a.** Aging
   - **b.** Family history
   - **c.** Obesity
   - **d.** Smoking
   - **e.** Stress
   - **f.** Excessive alcohol
   - **g.** Hyperlipidemia
   - **h.** Increased intake of salt or caffeine

C. Secondary hypertension

1. Secondary hypertension occurs as a result of other disorders or conditions.
2. Treatment depends on the cause and the organs involved.
3. Precipitating disorders or conditions
   - **a.** Cardiovascular disorders
   - **b.** Renal disorders
   - **c.** Endocrine system disorders
   - **d.** Pregnancy
   - **e.** Medications (e.g., estrogens, glucocorticoids, mineralocorticoids)

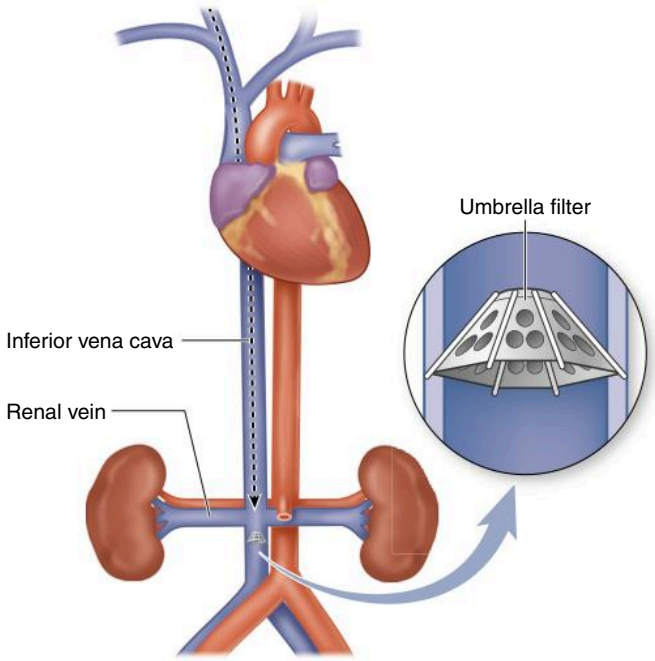

FIG. 53.14 An inferior vena cava filter.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

D. Assessment
1. May be asymptomatic
2. Headache
3. Visual disturbances
4. Dizziness
5. Chest pain
6. Tinnitus
7. Flushed face
8. Epistaxis

E. Interventions
1. Goals: To reduce the BP and to prevent or lessen the extent of organ damage
2. Question the client regarding the signs and symptoms of hypertension.
3. Obtain the BP two or more times on both arms, with the client supine and standing.
4. Compare the BP with prior documentation.
5. Determine family history of hypertension.
6. Identify current medication therapy.
7. Obtain weight.
8. Evaluate dietary patterns and sodium intake.
9. Assess for visual changes or retinal damage.
10. Assess for cardiovascular changes such as distended neck veins, increased heart rate, and dysrhythmias.
11. Evaluate chest x-ray for heart enlargement.
12. Assess the neurological system.
13. Evaluate renal function.
14. Evaluate results of diagnostic and laboratory studies.

F. Nonpharmacological interventions
1. Weight reduction, if necessary, or maintenance of ideal weight
2. Dietary sodium restriction to 2 g daily as prescribed
3. Moderate intake of alcohol and caffeine-containing products
4. Initiation of a regular exercise program
5. Avoidance of smoking
6. Relaxation techniques and biofeedback therapy
7. Elimination of unnecessary medications that may contribute to the hypertension

G. Pharmacological interventions
1. Medication therapy is individualized for each client, and the selection of the medication is based on such factors as the client's age, preferences, coexisting conditions, and hypertension severity.
2. See Chapter 54 for medications to treat hypertension.

H. See Box 53.10 for client education.

XXII. Hypertensive Crisis

A. Description
1. A hypertensive crisis is an acute and life-threatening condition requiring immediate reduction in BP.
2. Emergency treatment is required, because target organ damage (brain, heart, kidneys, retina of the eye) can occur quickly.
3. Death can be caused by stroke, kidney failure, or cardiac disease.

B. Assessment
1. An extremely high BP; systolic over 180 mm Hg and/or diastolic over 120 mm Hg
2. Headache
3. Drowsiness and confusion
4. Blurred vision
5. Changes in neurological status
6. Tachycardia and tachypnea
7. Dyspnea
8. Cyanosis
9. Seizures

C. Interventions
1. Maintain a patent airway.
2. Administer antihypertensive medications intravenously as prescribed.
3. Monitor vital signs, assessing the BP every 5 minutes.

BOX 53.10 Education for the Client with Hypertension

- Describe the importance of adherence with the treatment plan.
- Describe the disease process, explaining that symptoms usually do not develop until organs have suffered damage.
- Assist the client in planning a gradual regular exercise program, avoiding heavy weight-lifting and isometric exercises.
- Encourage the client to express feelings about daily stresses.
- Assist the client to identify ways to reduce stress.
- Teach relaxation techniques and encourage the client to incorporate them into the day.
- Instruct the client and family in the technique for monitoring blood pressure (BP).
- Instruct the client to maintain a diary of BP readings.
- Emphasize the importance of lifelong medication.
- Instruct the client and family about dietary restrictions, which may include sodium, fat, calories, and cholesterol.
- Instruct the client in how to shop for and prepare low-sodium meals.
- Provide a list of products that contain sodium.
- Instruct the client to read labels of products to determine sodium content, focusing on substances listed as sodium, NaCl, or MSG (monosodium glutamate).
- Instruct the client to bake, roast, or boil foods; to avoid salt in the preparation of foods; and to avoid the use of salt at the table.
- Instruct the client to consume fresh foods and to avoid canned foods.
- Instruct the client about the actions, side effects, and scheduling of medications.
- Advise the client that if uncomfortable side effects occur, to contact the primary health care provider or cardiologist and not to stop the medication.
- Instruct the client to avoid over-the-counter medications.
- Stress the importance of follow-up care.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Monitor neurological status.
5. Maintain bed rest, with the head of the bed elevated at 45 degrees.
6. Assess for hypotension during the administration of antihypertensives; place the client in a supine position if hypotension occurs.
7. Have emergency medications and resuscitation equipment readily available.
8. Monitor IV therapy, assessing for fluid overload.
9. Insert a Foley catheter as prescribed.
10. Monitor intake and urinary output; if oliguria or anuria occurs, notify the PHCP.

PRACTICE QUESTIONS

1. A client with a history of type 2 diabetes is admitted to the hospital with chest pain and scheduled for a cardiac catheterization. Which medication would need to be withheld for 24 hours before the procedure and for 48 hours after the procedure?
   1. Glipizide
   2. Metformin
   3. Repaglinide
   4. Regular insulin

2. A client in sinus bradycardia, with a heart rate of 45 beats per minute and blood pressure of 82/60 mm Hg, reports dizziness. Which intervention would the nurse anticipate will be prescribed?
   1. Administer digoxin.
   2. Defibrillate the client.
   3. Continue to monitor the client.
   4. Prepare for transcutaneous pacing.

3. The nurse in a medical unit is caring for a client with heart failure. The client suddenly develops extreme dyspnea, tachycardia, and lung crackles. The nurse immediately asks another nurse to contact the primary health care provider and prepares to implement which **priority** interventions? **Select all that apply.**
   - ❑ 1. Administering oxygen
   - ❑ 2. Inserting a Foley catheter
   - ❑ 3. Administering furosemide
   - ❑ 4. Administering morphine sulfate intravenously
   - ❑ 5. Transporting the client to the coronary care unit
   - ❑ 6. Placing the client in a low-Fowler's side-lying position

4. A client with myocardial infarction suddenly becomes tachycardic, shows signs of air hunger, and begins coughing frothy, pink-tinged sputum. Which finding would the nurse anticipate when auscultating the client's breath sounds?
   1. Stridor
   2. Crackles
   3. Scattered rhonchi
   4. Diminished breath sounds

5. A client with myocardial infarction is developing cardiogenic shock. Which potential condition would the nurse anticipate and monitor the client for to detect cardiogenic shock?
   1. Pulsus paradoxus
   2. Ventricular dysrhythmias
   3. Rising diastolic blood pressure
   4. Falling central venous pressure

6. The nurse is reviewing an electrocardiogram rhythm strip. The P waves and QRS complexes are regular. The PR interval is 0.16 seconds, and QRS complexes measure 0.06 seconds. The overall heart rate is 64 beats per minute. Which action would the nurse take?
   1. Check vital signs.
   2. Check laboratory test results.
   3. Monitor for any rhythm change.
   4. Notify the primary health care provider.

7. A client is wearing a continuous cardiac monitor, which begins to sound its alarm. The nurse sees no electrocardiographic complexes on the screen. Which is the **priority** nursing action?
   1. Call a code.
   2. Check the client's status.
   3. Call the primary health care provider.
   4. Document the lack of complexes.

8. The nurse is watching the cardiac monitor and notices that a client's rhythm suddenly changes. There are no P waves, the QRS complexes are wide, and the ventricular rate is regular but more than 140 beats per minute. The nurse determines that the client is experiencing which dysrhythmia?
   1. Sinus tachycardia
   2. Ventricular fibrillation
   3. Ventricular tachycardia
   4. Premature ventricular contractions

9. A client has frequent bursts of ventricular tachycardia on the cardiac monitor. Which factor is **highest priority** with regard to this dysrhythmia?
   1. It can develop into ventricular fibrillation at any time.
   2. It is almost impossible to convert to a normal rhythm.
   3. It is uncomfortable for the client, giving a sense of impending doom.
   4. It produces a high cardiac output with cerebral and myocardial ischemia.

10. A client is having frequent premature ventricular contractions. The nurse would place **priority** on assessment of which information?
    1. Causative factors, such as caffeine
    2. Sensation of fluttering or palpitations
    3. Blood pressure and oxygen saturation
    4. Precipitating factors, such as infection

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

11. The client has developed atrial fibrillation, with a ventricular rate of 150 beats per minute. Which associated findings would the nurse anticipate in the assessment? **Select all that apply.**
- ❑ 1. Syncope
- ❑ 2. Dizziness
- ❑ 3. Palpitations
- ❑ 4. Hypertension
- ❑ 5. Flat neck veins

12. A client's cardiac rhythm suddenly changes on the monitor. There are no P waves; instead, there are fibrillatory waves before each QRS complex. How would the nurse interpret the rhythm?
1. Atrial fibrillation
2. Sinus tachycardia
3. Ventricular fibrillation
4. Ventricular tachycardia

13. The nurse is assisting to defibrillate a client in ventricular fibrillation. Which intervention is a **priority** after placing the pads on the client's chest and before discharging the device?
1. Ensure that the client has been intubated.
2. Set the defibrillator to "synchronize" mode.
3. Administer an amiodarone bolus.
4. Confirm the cardiac rhythm.

14. A client in ventricular fibrillation is about to be defibrillated. Which energy level (in joules, J) would the nurse set on the monophasic defibrillator machine for the first delivery?
1. 50 J
2. 120 J
3. 200 J
4. 360 J

15. The nurse is evaluating a client's response to cardioversion. Which assessment would be the **priority**?
1. Blood pressure
2. Airway patency
3. Oxygen flow rate
4. Level of consciousness

16. The nurse is caring for a client who has just had implantation of an automatic internal cardioverter-defibrillator. Which assessment is the nursing **priority**?
1. Anxiety level of the client and family
2. Activation status and settings of the device
3. Presence of a MedicAlert card for the client to carry
4. Knowledge of restrictions on postdischarge physical activity

17. A client's electrocardiogram strip shows atrial and ventricular rates of 110 beats per minute. The PR interval is 0.14 seconds, the QRS complex measures 0.08 seconds, and the PP and RR intervals are regular. How would the nurse interpret this rhythm?
1. Sinus tachycardia
2. Sinus bradycardia
3. Sinus dysrhythmia
4. Normal sinus rhythm

18. The nurse is assessing the neurovascular status of a client who returned to the surgical nursing unit 4 hours ago after undergoing aortoiliac bypass graft. The affected leg is warm, and the nurse notes redness and edema. The pedal pulse is palpable. How would the nurse interpret the client's neurovascular status?
1. The neurovascular status is expected because of increased blood flow through the leg.
2. The neurovascular status is moderately impaired, and the surgeon needs to be called.
3. The neurovascular status is slightly deteriorating and needs to be monitored for another hour.
4. The neurovascular status shows adequate arterial flow, but venous complications are arising.

19. The nurse is caring for a client who had a resection of an abdominal aortic aneurysm yesterday. The client has an intravenous (IV) infusion at a rate of 150 mL/hr, unchanged for the last 10 hours. The client's urine output for the last 3 hours has been 90, 50, and 28 mL (28 mL is most recent). The client's blood urea nitrogen level is 35 mg/dL (12.6 mmol/L), and the serum creatinine level is 1.8 mg/dL (159 mcmol/L), measured this morning. Which nursing action is the **priority?**
1. Check the serum albumin level.
2. Check the urine specific gravity.
3. Continue to monitor urine output.
4. Call the primary health care provider.

20. A client with variant angina is scheduled to receive an oral calcium channel blocker twice daily. Which statement by the client indicates the **need for further teaching**?
1. "I need to notify my cardiologist if my feet or legs start to swell."
2. "I am supposed to report to my cardiologist if my pulse rate decreases below 60."
3. "Avoiding grapefruit juice will definitely be a challenge for me, since I usually drink it every morning with breakfast."
4. "My spouse told me that since I have this problem, we are going to stop walking in the mall every morning."

ANSWERS

1. *Answer:* 2

Rationale: Metformin needs to be withheld 24 hours before and for 48 hours after cardiac catheterization because of the injection of contrast medium during the procedure. If the contrast medium affects kidney function, with metformin in the system the client would be at increased risk for lactic acidosis. The medications in the remaining options do not need to be withheld before and after cardiac catheterization.

Test-Taking Strategy: Eliminate glipizide and repaglinide first because they are **comparable or alike**. Although these medications may be withheld on the morning of the procedure because of the client's NPO (nothing by mouth) status, there is no indication for withholding the medication on the day prior to the procedure and postprocedure. Regular insulin may be administered if elevated blood glucose levels from infused intravenous solutions occur on the day of the procedure.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 628-629, 1275.

2. *Answer:* 4

Rationale: Sinus bradycardia is noted with a heart rate of less than 60 beats per minute. This rhythm becomes a concern when the client becomes symptomatic. Hypotension and dizziness are signs of decreased cardiac output. Transcutaneous pacing provides a temporary measure to increase the heart rate and thus perfusion in the symptomatic client. Defibrillation is used for treatment of pulseless ventricular tachycardia and ventricular fibrillation. Digoxin will further decrease the client's heart rate. Continuing to monitor the client delays necessary intervention.

Test-Taking Strategy: Focus on the **subject,** interventions for sinus bradycardia. Eliminate the option indicating to continue to monitor the client, because the client is symptomatic and requires intervention. Digoxin is eliminated because it will further decrease the client's heart rate. Defibrillation is used for treatment of pulseless ventricular tachycardia and ventricular fibrillation, so that option can be eliminated.

Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 187, 190.

3. *Answer:* 1, 2, 3, 4

Rationale: Extreme dyspnea, tachycardia, and lung crackles in a client with heart failure indicate pulmonary edema, a life-threatening event. In pulmonary edema, the left ventricle fails to eject sufficient blood, and pressure increases in the lungs because of the accumulated blood. Oxygen is always prescribed, and the client is placed in a high-Fowler's position to ease the work of breathing. Furosemide, a rapid-acting diuretic, will eliminate accumulated fluid. A Foley catheter is inserted to measure output accurately. Intravenously administered morphine sulfate reduces venous return (preload), decreases anxiety, and also reduces the work of breathing. Transporting the client to the coronary care unit is not a priority intervention. In fact, this may not be necessary at all if the client's response to treatment is successful.

Test-Taking Strategy: Note the **strategic word,** *priority*, and focus on the client's diagnosis. Recall the pathophysiology associated with pulmonary edema, and use the **ABCs—airway, breathing, and circulation**—to help determine priority interventions.

Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 173-174.

4. *Answer:* 2

Rationale: Pulmonary edema is characterized by extreme breathlessness, dyspnea, air hunger, and the production of frothy, pink-tinged sputum. Auscultation of the lungs reveals crackles. Rhonchi and diminished breath sounds are not associated with pulmonary edema. Stridor is a crowing sound associated with laryngospasm or edema of the upper airway.

Test-Taking Strategy: Focus on the **subject,** breath sounds characteristic of pulmonary edema. Recalling that fluid produces sounds that are called *crackles* will assist you in eliminating the incorrect options.

Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 173.

5. *Answer:* 2

Rationale: Dysrhythmias commonly occur as a result of decreased oxygenation and severe damage to greater than 40% of the myocardium. Classic signs of cardiogenic shock as they relate to myocardial ischemia include low blood pressure and tachycardia. The central venous pressure would rise as the backward effects of the severe left ventricular failure become apparent. Pulsus paradoxus is a finding associated with cardiac tamponade.

Test-Taking Strategy: Focus on the **subject,** cardiogenic shock, and note the words *myocardial ischemia*. Recall that ischemia makes the myocardium irritable, producing dysrhythmias. Also, knowledge of the classic signs of shock helps eliminate the incorrect options.

Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 128, 156.

6. *Answer:* 3

Rationale: Normal sinus rhythm is defined as a regular rhythm, with an overall rate of 60 to 100 beats per minute. The PR and QRS measurements are normal, measuring between 0.12 and 0.20 seconds and 0.04 and 0.10 seconds, respectively. There are no irregularities in this rhythm currently, so there is no immediate need to check vital signs or laboratory results, or to notify the primary health care provider. Therefore, the nurse would continue to monitor the client for any rhythm change.

Test-Taking Strategy: Focus on the **subject,** electrocardiogram rhythm strip measurements. A baseline knowledge of normal electrocardiographic measurements is needed to answer this question. Focusing on the **data in the question** and recalling the characteristics of normal sinus rhythm will help you prioritize your actions.

Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 117-118, 122.

Telegram & Insta: NCLEX_RN_Edu

7. *Answer:* 2
Rationale: Sudden loss of electrocardiographic complexes indicates ventricular asystole or possibly electrode displacement. Accurate assessment of the client is necessary to determine the cause and identify the appropriate intervention. The remaining options are secondary to client assessment.
Test-Taking Strategy: Note the **strategic word**, *priority*. Use the **steps of the nursing process.** Always assess the client directly before taking any action related to equipment. The correct option is the only one that addresses assessment.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 669.

8. *Answer:* 3
Rationale: Ventricular tachycardia is characterized by the absence of P waves, wide QRS complexes (longer than 0.12 seconds), and typically a rate between 140 and 180 impulses per minute. The rhythm is regular.
Test-Taking Strategy: Focus on the **subject,** the characteristics of an electrocardiogram pattern, and note the **data in the question**. Eliminate sinus tachycardia first, because there are no P waves. Premature ventricular contractions are isolated ectopic beats superimposed on an underlying rhythm, so that option is eliminated next. Recalling that there are no true QRS complexes with ventricular fibrillation will direct you to the correct option from those remaining.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 766-767.

9. *Answer:* 1
Rationale: Ventricular tachycardia is a life-threatening dysrhythmia that results from an irritable ectopic focus that takes over as the pacemaker for the heart. Ventricular tachycardia can deteriorate into ventricular fibrillation with cardiac arrest at any time. Clients frequently experience a feeling of impending doom. The low cardiac output that results can lead quickly to cerebral and myocardial ischemia. Ventricular tachycardia is treated with antidysrhythmic medications, cardioversion (if the client is awake), or defibrillation (loss of consciousness).
Test-Taking Strategy: Note the **strategic words,** highest priority. The correct option identifies a life-threatening condition, so that is the highest priority. The option indicating that it is impossible to convert and the option indicating that it produces a high cardiac output are incorrect and are eliminated first. The client experiencing a feeling of impending doom is a concern that should be addressed promptly after interventions to stabilize the rhythm have begun.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 130.

10. *Answer:* 3
Rationale: Premature ventricular contractions can cause hemodynamic compromise. Therefore, the priority is to monitor the blood pressure and oxygen saturation. The shortened ventricular filling time can lead to decreased cardiac output. The client may be asymptomatic or may feel palpitations. Premature ventricular contractions can be caused by cardiac disorders; states of hypoxemia; any number of physiological stressors, such as infection, illness, surgery, or trauma; and intake of caffeine, nicotine, or alcohol.
Test-Taking Strategy: Note the **strategic word,** *priority*. Use the **ABCs—airway, breathing, and circulation**—to direct you to the correct option.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp.766-767; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 128-129.

11. *Answer:* 1, 2, 3
Rationale: The client with uncontrolled atrial fibrillation with a ventricular rate more than 100 beats per minute is at risk for low cardiac output because of loss of atrial kick. The nurse assesses the client for palpitations, chest pain or discomfort, hypotension, pulse deficit, fatigue, weakness, dizziness, syncope, shortness of breath, and distended neck veins. Hypertension and flat neck veins are not associated with the loss of cardiac output.
Test-Taking Strategy: Focus on the **subject,** signs and/or symptoms associated with atrial fibrillation. Flat neck veins are normal or indicate hypovolemia, so this option can be eliminated. From the remaining options, think of the consequences of a falling cardiac output to direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 652-653.

12. *Answer:* 1
Rationale: Atrial fibrillation is characterized by a loss of P waves and fibrillatory waves before each QRS complex. The atria quiver, which can lead to thrombus formation.
Test-Taking Strategy: Focus on the **subject,** interpreting a heart rhythm. Note the **data in the question.** Noting the words *There are no P waves* should direct you to the correct option. Loss of P waves is characteristic of this dysrhythmia.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 763-764.

13. *Answer:* 4
Rationale: Until the defibrillator is attached and charged, the client is resuscitated by using cardiopulmonary resuscitation. Once the defibrillator has been attached, the electrocardiogram is checked to verify that the rhythm is ventricular fibrillation or pulseless ventricular tachycardia. Leads also are checked for any loose connections. The client does not have to be intubated to be defibrillated. The machine is not set to the synchronous mode because there is no underlying rhythm with which to synchronize. Defibrillation should not be delayed for administration of any drugs, including amiodarone.

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Note the **strategic word,** *priority*. Focus on the **subject,** ventricular fibrillation. Note that the correct option directly addresses this subject and also addresses assessment of the client.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 769-770.

14. *Answer:* 4
Rationale: The energy level used for all defibrillation attempts with a monophasic defibrillator is 360 joules.
Test-Taking Strategy: Focus on the **subject,** monophasic defibrillation. As a general rule, though, remember that lower levels of energy are used for cardioversion and biphasic defibrillation. Higher levels are used in monophasic defibrillation.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 769.

15. *Answer:* 2
Rationale: Nursing responsibilities after cardioversion include maintenance first of a patent airway, and then oxygen administration, assessment of vital signs and level of consciousness, and dysrhythmia detection.
Test-Taking Strategy: Note the **strategic word**, *priority*. Use the **ABCs—airway, breathing, and circulation**—to direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 654.

16. *Answer:* 2
Rationale: The nurse who is caring for the client after insertion of an automatic internal cardioverter-defibrillator needs to assess device settings, similar to care after insertion of a permanent pacemaker. Specifically, the nurse needs to know whether the device is activated, the heart rate cutoff above which it will fire, and the number of shocks it is programmed to deliver. The remaining options are also nursing interventions but are not the priority.
Test-Taking Strategy: Note the **strategic word,** *priority*. Use **Maslow's Hierarchy of Needs theory**. The correct option is the one that identifies the physiological need.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 771.

17. *Answer:* 1
Rationale: Sinus tachycardia has the characteristics of normal sinus rhythm, including a regular PP interval and normal-width PR and QRS intervals; however, the rate is the differentiating factor. In sinus tachycardia, the atrial and ventricular rates are greater than 100 beats per minute.
Test-Taking Strategy: Focus on the **subject,** interpreting a cardiac rhythm. Eliminate sinus bradycardia and normal sinus rhythm first, because the ventricular rate is 110 beats per minute. Next eliminate sinus dysrhythmia, because this is an irregular rhythm, with changing PP and RR intervals.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 122.

18. *Answer:* 1
Rationale: An expected outcome of aortoiliac bypass graft surgery is warmth, redness, and edema in the surgical extremity because of increased blood flow. The remaining options are incorrect interpretations.
Test-Taking Strategy: Focus on the **subject,** expected outcomes following aortoiliac bypass graft surgery. Venous complications from immobilization resulting from surgery would not be apparent within 4 hours, so eliminate option 4. From the remaining options, note that the pedal pulse is unchanged from admission, and think about the effects of sudden reperfusion in an ischemic limb. There would be redness from new blood flow and edema from the sudden change in pressure in the blood vessels.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 715-716.

19. *Answer:* 4
Rationale: Following abdominal aortic aneurysm resection or repair, the nurse monitors the client for signs of acute kidney injury. Acute kidney injury can occur because often much blood is lost during the surgery and, depending on the aneurysm location, the renal arteries may be hypoperfused for a short period during surgery. Normal reference levels are BUN 10 to 20 mg/dL (3.6 to 7.1 mmol/L), and creatinine 0.5 to 1.2 mg/dL (44 to 106 mcmol/L). Continuing to monitor urine output or checking other parameters can wait. Urine output lower than 30 mL/hr is reported to the PHCP for urgent treatment.
Test-Taking Strategy: Note the **strategic word,** *priority*. Focus on the **data in the question** and the abnormal assessment data. This question indicates elevations in blood urea nitrogen and creatinine levels and a significant drop in hourly urine output. These assessment findings should direct you to an option that includes active collaboration with the PHCP.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 808-809, 812.

20. *Answer:* 4
Rationale: Variant angina, or Prinzmetal's angina, is prolonged and severe and occurs at the same time each day, most often at rest. The pain is a result of coronary artery spasm. The treatment of choice is usually a calcium channel blocker, which relaxes and dilates the vascular smooth muscle, thus relieving the coronary artery spasm in variant angina. Adverse effects can include peripheral edema, hypotension, bradycardia, and heart failure. Grapefruit juice interacts with calcium channel blockers and needs to be avoided. If bradycardia occurs, the client needs to contact the primary health care provider or cardiologist. Clients need to also be taught to change positions slowly to prevent orthostatic

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

hypotension. Physical exertion does not cause this type of angina; therefore, the client would be able to continue morning walks with their spouse.

Test-Taking Strategy: Note the **strategic words,** *need for further teaching,* and focus on the **data in the question.** These words indicate a **negative event query** and the need to select the incorrect client statement. Recall that walking is a low-impact exercise and is usually recommended for clients with heart problems.

Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 152.

CHAPTER 54

Cardiovascular Medications

Contributors: Debra Hagler, PhD, RN, aCNS-BC, cNE, CHSE, ANEF, FAAN
Diana Rabbani Hagler, MSN-Ed, RN, CCRN
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS Health Promotion; Perfusion

I. Anticoagulants (Box 54.1)

A. Description

1. Anticoagulants prevent the extension and formation of clots by inhibiting factors in the clotting cascade and decreasing blood coagulability.

2. Anticoagulants are administered when there is evidence of or likelihood of clot formation—myocardial infarction, unstable angina, atrial fibrillation, deep vein thrombosis, pulmonary embolism, and the presence of mechanical heart valves.

3. Anticoagulants are contraindicated with active bleeding (except for disseminated intravascular coagulation), bleeding disorders or blood dyscrasias, ulcers, liver and kidney disease, and hemorrhagic brain injuries (Box 54.2).

B. Side and adverse effects

1. Hemorrhage
2. Hematuria
3. Epistaxis
4. Ecchymosis
5. Bleeding gums
6. Thrombocytopenia
7. Hypotension

C. Heparin sodium

1. Description

a. Heparin prevents thrombin from converting fibrinogen to fibrin.
b. Heparin prevents thromboembolism.
c. The therapeutic dose does not dissolve clots but prevents new thrombus formation.

2. Blood levels

a. The normal activated partial thromboplastin time (aPTT) is 30 to 40 seconds (conventional and SI units) in most laboratories (values depend on reagent and instrumentation used).
b. To maintain a therapeutic level of anticoagulation when the client is receiving a continuous infusion of heparin, the aPTT should be 1.5 to 2.5 times the normal value. Some agencies use two different protocols, a high-intensity protocol such as for acute coronary syndrome and a low-intensity protocol such as for venous thromboembolism prophylaxis, and the dosages and recommended aPTT ranges are slightly different for the two protocols.
c. Activated partial thromboplastin time therapy should be measured every 4 to 6 hours during initial continuous infusion therapy or until the client has been therapeutic for a specified time frame and then daily per agency policy.
d. If the aPTT is too long, per agency procedure, the dosage should be lowered.
e. If the aPTT is too short, per agency procedure, the dosage should be increased.

3. Interventions

a. Monitor aPTT.
b. Monitor platelet count.
c. Observe for bleeding gums, bruises, nosebleeds, hematuria, hematemesis, occult blood in the stool, and petechiae.
d. Instruct the client regarding measures to prevent bleeding.
e. The antidote to heparin is protamine sulfate.
f. When administering heparin subcutaneously, inject into the abdomen with a ⅝-inch (16-mm) needle (25 to 28 gauge) at a 90-degree angle and do not aspirate or rub the injection site.
g. Continuous IV infusions must be run on an infusion pump to ensure a precise rate of delivery.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 54.1 Anticoagulants

Oral
- Apixaban
- Dabigatran etexilate mesylate
- Edoxaban
- Rivaroxaban
- Warfarin sodium

Parenteral
- Argatroban
- Bivalirudin
- Dalteparin
- Desirudin
- Enoxaparin
- Fondaparinux
- Heparin sodium

BOX 54.2 Substances to Avoid with Anticoagulants

- Allopurinol
- Cimetidine
- Corticosteroids
- Fluoroquinolones
- Ginkgo and ginseng (herbs)
- Green, leafy vegetables and other foods high in vitamin K
- Macrolide antibiotics
- Nonsteroidal antiinflammatory drugs
- Oral hypoglycemic agents
- Phenytoin
- Salicylates
- Sulfonamides

D. Enoxaparin or Rivaroxaban—low-molecular-weight heparins
1. Description: Enoxaparin and rivaroxaban have the same mechanism of action and use as heparin but are not interchangeable with heparin; they have longer half-lives than heparin does.
2. Interventions
   - **a.** Administer enoxaparin only to the recumbent client by subcutaneous injection into the anterolateral or posterolateral abdominal wall; do not expel the air bubble from the prefilled syringe or aspirate during injection.
   - **b.** Rivaroxaban is taken orally, once daily.
   - **c.** Monitor results of the Anti-Xa assay. The therapeutic range for anticoagulation is 0.5 to 1.2 IU/mL (conventional and SI units). Observe for bleeding.
   - **d.** The antidote to low-molecular-weight heparins is protamine sulfate.

E. Warfarin sodium
1. Description
   - **a.** Warfarin suppresses coagulation by acting as an antagonist of vitamin K by inhibiting four dependent clotting factors (X, IX, VII, and II).
   - **b.** Warfarin prolongs clotting time and is monitored by the prothrombin time (PT) and the international normalized ratio (INR).
   - **c.** It is used for long-term anticoagulation and is used mainly to prevent thromboembolic conditions such as thrombophlebitis, pulmonary embolism, and embolism formation caused by atrial fibrillation, thrombosis, myocardial infarction, or heart valve damage.
2. Blood levels
   - **a.** The normal PT is 11 to 12.5 seconds (conventional and SI units).
   - **b.** Warfarin sodium prolongs the PT; the therapeutic range is 1.5 to 2 times the control value.
3. INR
   - **a.** The normal INR is 0.81 to 1.2 (conventional and SI units).
   - **b.** The INR is determined by multiplying the observed PT ratio (the ratio of the client's PT to a control PT) by a correction factor specific to a particular thromboplastin preparation used in the testing.
   - **c.** The treatment goal of warfarin sodium is to raise the INR to an appropriate value.
   - **d.** An INR of 2 to 3 is appropriate for standard warfarin therapy; an INR of 3 to 4.5 is appropriate for high-dose warfarin therapy.
   - **e.** If the PT value is longer than 30 seconds and the INR is greater than 3.0 in a client receiving standard warfarin therapy, initiate bleeding precautions.
   - **f.** If the INR is below the recommended range, warfarin sodium dose should be increased.
   - **g.** Clients may sometimes be prescribed "bridge therapy," whereby heparin sodium is used concurrently with warfarin sodium until the INR reaches the recommended range. Once this occurs, the heparin is discontinued.
4. Interventions
   - **a.** Monitor PT and INR.
   - **b.** Observe for bleeding gums, bruises, nosebleeds, hematuria, hematemesis, occult blood in the stool, and petechiae.
   - **c.** Instruct the client regarding diet and measures to prevent bleeding.
   - **d.** The antidote for warfarin is phytonadione.

F. Dabigatran etexilate
1. Description
   - **a.** Dabigatran etexilate works through direct inhibition of thrombin, preventing the conversion of fibrinogen into fibrin and activation of factor XIII.
   - **b.** Current approved use is for clot prevention associated with nonvalvular atrial fibrillation.
   - **c.** It is administered in a fixed dose twice daily.
2. Blood levels: No blood testing is required.
3. Interventions: Same as for warfarin, except no routine monitoring is required.

Telegram & Insta: NCLEX_RN_Edu

BOX 54.3 Thrombolytic Medications

- Alteplase
- Reteplase
- Tenecteplase

BOX 54.4 Antiplatelet Medications

Oral
- Acetylsalicylic acid
- Anagrelide
- Cilostazol
- Clopidogrel
- Dipyridamole
- Ticagrelor
- Ticlopidine

Parenteral
- Abciximab
- Eptifibatide
- Tirofiban

II. Thrombolytic Medications (Box 54.3)

A. Description
1. Thrombolytic medications activate plasminogen; plasminogen generates plasmin (the enzyme that dissolves clots).
2. Thrombolytic medications are used early in the course of myocardial infarction (within 4 to 6 hours of the onset of the infarct) to restore blood flow, limit myocardial damage, preserve left ventricular function, and prevent death.
3. Thrombolytics are also used in arterial thrombosis, deep vein thrombosis, occluded shunts or catheters, pulmonary emboli, and ischemic stroke.

B. Contraindications
1. Active internal bleeding
2. History of hemorrhagic stroke
3. Intracranial problems, including trauma
4. Intracranial or intraspinal surgery within the previous 2 months
5. Thoracic, pelvic, or abdominal surgery in the previous 10 days
6. History of hepatic or renal disease
7. Uncontrolled hypertension
8. Recent, prolonged cardiopulmonary resuscitation
9. Known allergy to the product or its preservatives

C. Side and adverse effects
1. Bleeding
2. Dysrhythmias
3. Allergic reactions

D. Interventions
1. Determine aPTT, PT, fibrinogen level, hematocrit, and platelet count.
2. Monitor vital signs.
3. Assess pulses.
4. Monitor for bleeding, and check all excretions for occult blood.
5. Monitor for neurological changes such as slurred speech, lethargy, confusion, and hemiparesis.
6. Monitor for hypotension and tachycardia.
7. Avoid injections and venipunctures if possible.
8. Apply direct pressure over a puncture site for 20 to 30 minutes.
9. Handle the client gently and as little as possible when moving.
10. Instruct the client to use an electric razor for shaving and to brush teeth gently.
11. Withhold the medication if bleeding develops, and notify the primary health care provider (PHCP).
12. Antidote: Aminocaproic acid is the antidote.

! Bleeding is the primary concern for a client taking an anticoagulant, thrombolytic, or antiplatelet medication.

III. Antiplatelet Medications (Box 54.4)

A. Description
1. Antiplatelet medications inhibit the aggregation of platelets in the clotting process, thereby prolonging the bleeding time.
2. Antiplatelet medications may be used with anticoagulants.
3. Used in the prophylaxis of long-term complications following myocardial infarction, coronary revascularization, stents, and stroke
4. These medications are contraindicated in those with bleeding disorders and known sensitivity.

B. Side and adverse effects
1. Bruising
2. Hematuria
3. Gastrointestinal bleeding
4. Tarry stools

C. Interventions
1. A blood test may be prescribed to determine the client's sensitivity to the medication before beginning administration.
2. Monitor vital signs.
3. Instruct the client to take medication with food if gastrointestinal upset occurs.
4. Monitor bleeding time.
5. Instruct the client to monitor for side and adverse effects and in the measures to prevent bleeding.

IV. Positive Inotropic and Cardiotonic Medications (Box 54.5)

A. Description
1. These medications stimulate myocardial contractility and produce a positive inotropic effect.
2. These medications are used for short-term management of advanced heart failure; the increase in myocardial contractility improves cardiac, peripheral, and kidney function by increasing

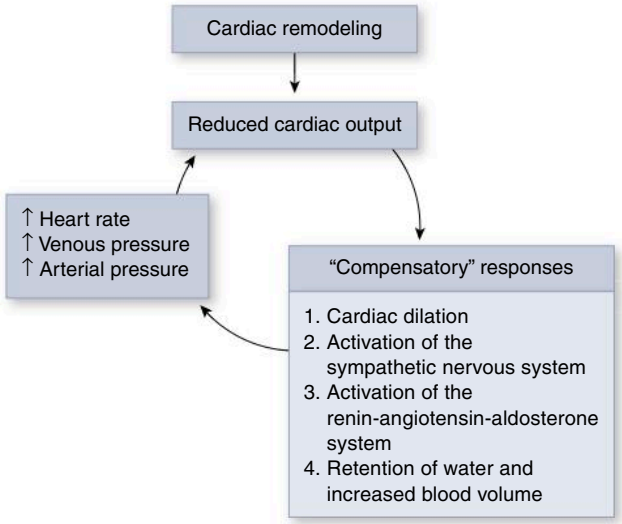
Telegram & Insta: NCLEX_RN_Edu

BOX 54.5 Positive Inotropic and Cardiotonic Medications

Dobutamine
- Used for short-term management of heart failure
- Increases myocardial contractility, thereby improving cardiac performance

Dopamine
- Used as a short-term rescue measure for clients with severe, acute heart failure
- Increases myocardial contractility, thereby improving cardiac performance
- Dilates renal blood vessels and increases renal blood flow and urine output

Milrinone Lactate
- Used for short-term management of heart failure; may be given before heart transplantation



Cardiac remodeling
Reduced cardiac output
↑ Heart rate
↑ Venous pressure
↑ Arterial pressure
"Compensatory" responses
1. Cardiac dilation
2. Activation of the sympathetic nervous system
3. Activation of the renin-angiotensin-aldosterone system
4. Retention of water and increased blood volume

FIG. 54.1 The vicious cycle of maladaptive compensatory responses to a failing heart.

cardiac output, decreasing preload, improving blood flow to the periphery and kidneys, decreasing edema, and increasing fluid excretion. As a result, fluid retention in the lungs and extremities is decreased (Fig. 54.1).

B. Side and adverse effects
1. Dysrhythmias
2. Hypotension
3. Thrombocytopenia
4. Hepatotoxicity manifested by elevated liver enzyme levels
5. Hypersensitivity manifested by wheezing, shortness of breath, pruritus, urticaria, clammy skin, and flushing

C. Interventions
1. Positive inotropic and cardiotonic medications are administered intravenously.
   a. For continuous intravenous (IV) infusion, administer with an infusion pump.
   b. Stop the infusion if the client's blood pressure (BP) drops or dysrhythmias occur.
2. Monitor the apical pulse and BP.
3. Monitor for hypersensitivity.
4. Assess lung sounds for wheezing and crackles.
5. Monitor for edema.
6. Monitor for relief of heart failure as noted by reduction in edema and lessening of dyspnea, orthopnea, and fatigue.
7. Monitor electrolyte and liver enzyme levels, platelet count, and renal function studies; the medications may decrease potassium and increase liver enzyme levels; continuous electrocardiographic monitoring is done during administration.

V. Cardiac Glycosides

A. Digoxin
1. Description
   a. Cardiac glycosides inhibit the sodium-potassium pump, thus increasing intracellular calcium, which causes the heart muscle fibers to contract more efficiently.
   b. Cardiac glycosides produce a positive inotropic action, which increases the force of myocardial contractions.
   c. Cardiac glycosides produce a negative chronotropic action, which slows the heart rate.
   d. Cardiac glycosides produce a negative dromotropic action, which slows conduction velocity through the atrioventricular (AV) node.
   e. The increase in myocardial contractility increases cardiac, peripheral, and kidney function by increasing cardiac output, decreasing preload, improving blood flow to the periphery and kidneys, decreasing edema, and increasing fluid excretion; as a result, fluid retention in the lungs and extremities is decreased.
   f. Cardiac glycosides are a second-line medication for heart failure (medications affecting the renin-angiotensin-aldosterone system are used more often) and cardiogenic shock, atrial tachycardia, atrial fibrillation, and atrial flutter; they are used less frequently for rate control in atrial dysrhythmias (beta blockers and calcium channel blockers are used more often).
   g. These medications are contraindicated in those with ventricular dysrhythmias and second- or third-degree heart block. They should

Telegram & Insta: NCLEX_RN_Edu

be used with caution in clients with renal disease, hypothyroidism, and hypokalemia.

2. Side and adverse effects
   - **a.** Anorexia, nausea, vomiting, diarrhea
   - **b.** Bradycardia
   - **c.** Visual disturbances: Diplopia, blurred vision, yellow vision, photophobia
   - **d.** Headache
   - **e.** Fatigue, weakness
   - **f.** Drowsiness

Early signs of digoxin toxicity present as gastrointestinal manifestations (anorexia, nausea, vomiting, diarrhea); then, heart rate abnormalities and visual disturbances appear.

3. Interventions
   - **a.** Monitor for toxicity as evidenced by anorexia, nausea, vomiting, visual disturbances (blurred or yellow vision), and dysrhythmias.
   - **b.** Monitor serum digoxin level, electrolyte levels, and renal function test results.
   - **c.** The optimal therapeutic range for digoxin is 0.5 to 2.0 ng/dL (0.63 to 2.56 nmol/L). However, a level on the low end of normal may be preferred to avoid toxicity.
   - **d.** An increased risk of toxicity exists in clients with hypercalcemia, hypokalemia, hypomagnesemia, or hypothyroidism.
   - **e.** Note that older clients are more sensitive to digoxin toxicity.
   - **f.** Monitor the potassium level; if hypokalemia occurs (potassium lower than 3.5 mEq/L [3.5 mmol/L]), notify the PHCP.
   - **g.** Monitor the client taking a potassium-losing diuretic or corticosteroids closely for hypokalemia, because the hypokalemia can cause digoxin toxicity.
   - **h.** Instruct the client to avoid over-the-counter medications.
   - **i.** Advise the client to eat foods high in potassium, such as fresh and dried fruits, fruit juices, vegetables, and potatoes.
   - **j.** Monitor the apical pulse for 1 full minute; if the apical pulse rate is lower than 60 beats per minute, the medication should be withheld and the PHCP notified.
   - **k.** Teach the client how to measure the pulse and to notify the PHCP if the pulse rate is lower than 60 or more than 100 beats per minute.
   - **l.** Teach the client the signs and symptoms of toxicity.
   - **m.** Antidote: Digoxin immune Fab is used in extreme toxicity.

BOX 54.6 Classifications of Diuretics

- Aldosterone antagonists
- Loop diuretics
- Potassium-sparing diuretics
- Thiazide diuretics

BOX 54.7 Thiazide and Thiazide-Like Diuretics

- Chlorothiazide
- Chlorthalidone
- Hydrochlorothiazide
- Indapamide
- Metolazone

VI. Antihypertensive Medications: Diuretics (Box 54.6)

A. Thiazide diuretics (Box 54.7)

1. Description
   - **a.** Thiazide diuretics increase sodium and water excretion by inhibiting sodium reabsorption in the distal tubule of the kidney.
   - **b.** Used for hypertension and peripheral edema
   - **c.** Not effective for immediate diuresis
   - **d.** Used in clients with normal renal function (contraindicated in clients with renal failure)
   - **e.** Thiazide diuretics should be used with caution in the client taking lithium, because lithium toxicity can occur, and in the client taking digoxin, corticosteroids, or hypoglycemic medications.
2. Side and adverse effects
   - **a.** Hypercalcemia, hyperglycemia, hyperuricemia
   - **b.** Hypokalemia, hyponatremia
   - **c.** Hypovolemia
   - **d.** Hypotension
   - **e.** Rashes
   - **f.** Photosensitivity
   - **g.** Dehydration
3. Interventions
   - **a.** Monitor vital signs.
   - **b.** Monitor weight.
   - **c.** Monitor urine output.
   - **d.** Monitor electrolytes, glucose, calcium, blood urea nitrogen (BUN), creatinine, and uric acid levels.
   - **e.** Check peripheral extremities for edema.
   - **f.** Monitor for signs of digoxin or lithium toxicity if the client is taking these medications.
   - **g.** Instruct the client to take the medication in the morning to avoid nocturia and sleep interruption.
   - **h.** Instruct the client in how to record the BP.
   - **i.** Instruct the client to eat foods high in potassium.

Telegram & Insta: NCLEX_RN_Edu

BOX 54.8 Loop Diuretics

- Bumetanide
- Ethacrynic acid
- Furosemide
- Torsemide

BOX 54.9 Potassium-Sparing Diuretics

- Amiloride hydrochloride
- Eplerenone
- Spironolactone
- Triamterene

j. Instruct the client in how to take potassium supplements if prescribed.
k. Instruct the client to take medication with food to avoid gastrointestinal upset.
l. Instruct the client to change positions slowly to prevent orthostatic hypotension.
m. Instruct the client to use sunscreen when in direct sunlight because of increased photosensitivity.
n. Instruct the client with diabetes mellitus to have the blood glucose level checked periodically.

B. Loop diuretics (Box 54.8)
1. Description
a. Loop diuretics inhibit sodium and chloride reabsorption from the loop of Henle and the distal tubule.
b. Loop diuretics have little effect on the blood glucose level; however, they cause depletion of water and electrolytes, increased uric acid levels, and the excretion of calcium.
c. Loop diuretics are more potent than thiazide diuretics, causing rapid diuresis, thus decreasing vascular fluid volume, cardiac output, and BP.
d. Used for hypertension, pulmonary edema, edema associated with heart failure, hypercalcemia, and renal disease
e. Use loop diuretics with caution in the client taking digoxin or lithium and in the client taking aminoglycosides, anticoagulants, corticosteroids, or amphotericin B.
2. Side and adverse effects
a. Hypokalemia, hyponatremia, hypocalcemia, hypomagnesemia
b. Thrombocytopenia
c. Hyperuricemia
d. Orthostatic hypotension
e. Rash
f. Ototoxicity and deafness
g. Thiamine deficiency
h. Dehydration
3. Interventions: See section VI, A, 3 (Interventions for thiazide diuretics).
a. Monitor electrolytes, calcium, magnesium, BUN, creatinine, and uric acid levels.
b. Administer IV furosemide slowly over 1 to 2 minutes, because hearing loss can occur if injected rapidly.

C. Aldosterone antagonists (osmotic diuretics): See Chapter 60.
D. Potassium-sparing diuretics (Box 54.9)
1. Description
a. Potassium-sparing diuretics act on the distal tubule to promote sodium and water excretion and potassium retention.
b. Used for edema and hypertension, to increase urine output, and to treat fluid retention and overload associated with heart failure, ascites resulting from cirrhosis or nephrotic syndrome, and diuretic-induced hypokalemia
c. Potassium-sparing diuretics are contraindicated in severe kidney or hepatic disease and in severe hyperkalemia.
d. Potassium-sparing diuretics should be used with caution in clients with diabetes mellitus, clients taking antihypertensives or lithium, or clients taking angiotensin-converting enzyme inhibitors or potassium supplements because hyperkalemia can result.

The primary concern with administering potassium-sparing diuretics is hyperkalemia.

2. Side and adverse effects
a. Hyperkalemia
b. Nausea, vomiting, diarrhea
c. Rash
d. Dizziness, weakness
e. Headache
f. Dry mouth
g. Photosensitivity
h. Anemia
i. Thrombocytopenia
3. Interventions
a. Monitor vital signs.
b. Monitor urine output.
c. Monitor for signs and symptoms of hyperkalemia such as nausea; diarrhea; abdominal cramps; tachycardia followed by bradycardia; tall, peaked T waves on the electrocardiogram; and oliguria.
d. Monitor for a potassium level greater than 5.0 mEq/L (5.0 mmol/L), which indicates hyperkalemia.
e. Instruct the client to avoid foods high in potassium.

Telegram & Insta: NCLEX_RN_Edu

f. Instruct the client to avoid exposure to direct sunlight.
g. Instruct the client to monitor for signs of hyperkalemia.
h. Instruct the client to avoid salt substitutes because they contain potassium.
i. Instruct the client to take the medication with or after meals to decrease gastrointestinal irritation.

VII. Peripherally Acting α-Adrenergic Blockers (Box 54.10)

A. Description
1. These medications decrease sympathetic vasoconstriction by reducing the effects of norepinephrine at peripheral nerve endings, resulting in vasodilation and decreased BP.
2. These medications are used to treat hypertension and maintain renal blood flow.

B. Side and adverse effects
1. Orthostatic hypotension
2. Reflex tachycardia
3. Sodium and water retention
4. Edema
5. Weight gain
6. Gastrointestinal disturbances
7. Drowsiness
8. Nasal congestion

C. Interventions
1. Monitor vital signs.
2. Monitor for fluid retention and edema.
3. Instruct the client to change positions slowly to prevent orthostatic hypotension.
4. Instruct the client in how to monitor the BP.
5. Instruct the client to monitor for edema.
6. Instruct the client to decrease salt intake.
7. Instruct the client to avoid over-the-counter medications.

VIII. Centrally Acting Sympatholytics (Adrenergic Blockers) (Box 54.11)

A. Description
1. Centrally acting sympatholytics stimulate α-receptors in the central nervous system to inhibit vasoconstriction, thus reducing peripheral resistance.
2. Used to treat hypertension
3. Contraindicated in impaired liver function

B. Side and adverse effects
1. Sodium and water retention
2. Edema
3. Drowsiness, dizziness
4. Dry mouth
5. Hypotension
6. Bradycardia
7. Impotence
8. Depression

BOX 54.10 Peripherally Acting α-Adrenergic Blockers

- Doxazosin
- Prazosin
- Terazosin

BOX 54.11 Centrally Acting Sympatholytics (Adrenergic Blockers)

- Clonidine
- Guanfacine
- Methyldopa

BOX 54.12 Angiotensin-Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers

Angiotensin-Converting Enzyme Inhibitors
- Benazepril
- Captopril
- Enalapril
- Fosinopril
- Lisinopril
- Moexipril
- Perindopril
- Quinapril
- Ramipril
- Trandolapril

Angiotensin II Receptor Blockers
- Azilsartan
- Candesartan
- Eprosartan
- Irbesartan
- Losartan
- Olmesartan
- Telmisartan
- Valsartan

C. Interventions
1. Monitor vital signs.
2. Instruct the client not to discontinue medication, because abrupt withdrawal can cause severe rebound hypertension.
3. Monitor liver function tests.

IX. Angiotensin-Converting Enzyme (ACE) Inhibitors and Angiotensin II Receptor Blockers (ARBs) (Box 54.12)

A. Description
1. ACE inhibitors prevent peripheral vasoconstriction by blocking conversion of angiotensin I to angiotensin II (AII).
2. ARBs prevent peripheral vasoconstriction and secretion of aldosterone and block the binding of AII to type 1 AII receptors.
3. These medications are used to treat hypertension and heart failure; also, ACE inhibitors are administered for their cardioprotective effect after myocardial infarction.
4. Avoid use with potassium supplements and potassium-retaining (sparing) diuretics.

Telegram & Insta: NCLEX_RN_Edu

B. Side and adverse effects
1. Nausea, vomiting, diarrhea
2. Persistent dry cough (ACE inhibitors)
3. Hypotension
4. Hyperkalemia
5. Tachycardia
6. Headache
7. Dizziness, fatigue
8. Insomnia
9. Hypoglycemic reaction in the client with diabetes mellitus
10. Bruising, petechiae, bleeding
11. Diminished taste (ACE inhibitors)

⚠ A persistent dry cough is common for those taking an ACE inhibitor, but this often subsides after a few weeks. Instruct the client to contact the PHCP if this occurs and persists.

C. Interventions
1. Monitor vital signs.
2. Monitor white blood cells, and protein, albumin, BUN, creatinine, and potassium levels.
3. Monitor for hypoglycemic reactions in the client with diabetes mellitus.
4. If captopril is prescribed, instruct the client to take the medication 20 to 60 minutes before a meal.
5. Monitor for bruising, petechiae, or bleeding with captopril.
6. Instruct the client not to discontinue medications, because rebound hypertension can occur.
7. Instruct the client not to take over-the-counter medications.
8. Instruct the client in how to take the BP.
9. Inform the client that the taste of food may be diminished during the first month of therapy.
10. Instruct the client to report adverse effects to the PHCP.

X. Antianginal Medications (Box 54.13)

A. Nitrates (see Clinical Judgment: Take Action Box)
1. Description
   - **a.** Nitrates produce vasodilation, decrease preload and **afterload**, and reduce myocardial oxygen consumption.

BOX 54.13 Antianginal Medications (Organic Nitrates)

- Isosorbide dinitrate
- Isosorbide mononitrate
- Nitroglycerin, sublingual
- Nitroglycerin, translingual
- Nitroglycerin, transdermal patches
- Nitroglycerin ointment
- Intravenous nitroglycerin

   - **b.** Contraindicated in the client with significant hypotension, increased intracranial pressure, or severe anemia and in those taking medication to treat erectile dysfunction
   - **c.** Should be used with caution with severe renal or hepatic disease
   - **d.** Avoid abrupt withdrawal of long-acting preparations to prevent the rebound effect of severe pain from myocardial ischemia.
2. Side and adverse effects
   - **a.** Headache
   - **b.** Orthostatic hypotension
   - **c.** Dizziness, weakness
   - **d.** Faintness
   - **e.** Flushing or pallor
   - **f.** Dry mouth
   - **g.** Reflex tachycardia
3. Sublingual medications
   - **a.** Monitor vital signs.
   - **b.** Offer sips of water before giving, because dryness may inhibit medication absorption.
   - **c.** Instruct the client to sit down before taking the medication because of the potential for dizziness and risk of falling.
   - **d.** Instruct the client to place under the tongue and leave until fully dissolved.
   - **e.** Instruct the client not to swallow the medication.
   - **f.** Instruct the at-home client to take 1 tablet for pain and to immediately contact emergency medical services if pain is not relieved; in the hospitalized client, 1 tablet is administered every 5 minutes for a total of three doses, and the PHCP is notified immediately if pain is not relieved following the three doses (the BP is checked before each administration).
   - **g.** Inform the client that a stinging or burning sensation may indicate that the tablet is fresh.
   - **h.** Instruct the client to store medication in a dark, tightly closed bottle.
   - **i.** Instruct the client to take acetaminophen for a headache.

⚠ Instruct the client using nitroglycerin tablets to check the expiration date on the medication bottle, because expiration may occur within 6 months of obtaining the medication. The tablets will not relieve chest pain if they have expired.

4. Translingual medications (spray)
   - **a.** Instruct the client to direct the spray against the oral mucosa.
   - **b.** Instruct the client to avoid inhaling the spray.
5. Sustained-released medications: Instruct the client to swallow and not to chew or crush the medication.
6. Transdermal patch

Telegram & Insta: NCLEX_RN_Edu

   a. Instruct the client to apply the patch to a hairless area, using a new patch and different site each day.
   b. As prescribed, instruct the client to remove the patch after 12 to 14 hours, allowing 10 to 12 "patch-free" hours each day to prevent tolerance.
7. Topical ointments
   a. Instruct the client to remove the ointment on the skin from the previous dose.
   b. Instruct the client to squeeze a ribbon of ointment of the prescribed length onto the applicator or dose-measuring paper.
   c. Instruct the client to spread the ointment over a 2.5- by 3.5-inch (6.5 by 9 cm) area and cover with plastic wrap, using the chest, back, abdomen, upper arm, or anterior thigh (avoid hairy areas).
   d. Instruct the client to rotate sites and to avoid touching the ointment when applying.
8. Patches and ointments
   a. Wear gloves when applying.
   b. Do not apply on the chest in the area of defibrillator-cardioverter pad placement, because skin burns can result if the pads need to be used.

CLINICAL JUDGMENT: TAKE ACTION

The nurse is caring for a hospitalized client with coronary artery disease. The client calls the nurse and reports substernal crushing chest pain that radiates to the left arm. The nurse takes the following actions:

- Quickly assesses the client, specifically characteristics of pain, heart rate and rhythm, and blood pressure (BP)
- Administers a nitroglycerin tablet sublingually
- Stays with the client
- Reassesses the client in 5 minutes
- Administers another nitroglycerin tablet sublingually if pain is not relieved and the BP is stable
- Reassesses the client in 5 minutes
- Administers a third nitroglycerin tablet sublingually if pain is not relieved and the BP is stable
- Reassesses in 5 minutes; contacts the PHCP if the third nitroglycerin tablet does not relieve the pain
- Documents the event, actions taken, and the client's response to treatment

XI. β-Adrenergic Blockers (Box 54.14)

A. Description
1. β-Adrenergic blockers inhibit response to β-adrenergic stimulation, thus decreasing cardiac output.

BOX 54.14 β-Adrenergic Blockers

Nonselective (Block β_1 and β_2)	Cardioselective (Block β_1)
Carvedilol	Acebutolol
Labetalol	Atenolol
Nadolol	Betaxolol
Pindolol	Bisoprolol
Propranolol	Esmolol
Sotalol	Metoprolol
	Nebivolol

2. They block the release of catecholamines, epinephrine, and norepinephrine, thus decreasing the heart rate and BP; they also decrease the workload of the heart and decrease oxygen demands.
3. Used for angina, dysrhythmias, hypertension, migraine headaches, prevention of myocardial infarction, and glaucoma
4. β-Adrenergic blockers are contraindicated in the client with asthma, bradycardia, heart failure (with exceptions), severe renal or hepatic disease, hyperthyroidism, or stroke; carvedilol, metoprolol, and bisoprolol have been approved for use in heart failure once the client has been stabilized by ACE inhibitor and diuretic therapy.
5. β-Adrenergic blockers should be used with caution in the client with diabetes mellitus, because the medication may mask symptoms of hypoglycemia.
6. β-Adrenergic blockers should be used with caution in the client taking antihypertensive medications.

B. Side and adverse effects
1. Bradycardia
2. Bronchospasm
3. Hypotension
4. Weakness, fatigue
5. Nausea, vomiting
6. Dizziness
7. Hyperglycemia
8. Agranulocytosis
9. Behavioral or psychotic response
10. Depression
11. Nightmares

C. Interventions
1. Monitor vital signs.
2. Withhold the medication if the pulse or BP is not within the prescribed parameters.
3. Monitor for signs of heart failure or worsening heart failure.
4. Assess for respiratory distress and for signs of wheezing and dyspnea.
5. Instruct the client to report dizziness, lightheadedness, or nasal congestion.

Telegram & Insta: NCLEX_RN_Edu

BOX 54.15 Calcium Channel Blockers

- Amlodipine
- Clevidipine
- Diltiazem
- Felodipine
- Isradipine
- Levamlodipine
- Nicardipine
- Nifedipine
- Nimodipine
- Nisoldipine
- Verapamil

6. Instruct the client not to stop the medication, because rebound hypertension, rebound tachycardia, or an anginal attack can occur.
7. Advise the client taking insulin that the β-adrenergic blocker can mask early signs of hypoglycemia, such as tachycardia and nervousness.
8. Instruct the client taking insulin to monitor the blood glucose level.
9. Instruct the client in how to take pulse and BP.
10. Instruct the client to change positions slowly to prevent orthostatic hypotension.
11. Instruct the client to avoid over-the-counter medications, especially cold medications and nasal decongestants.

XII. Calcium Channel Blockers (Box 54.15)

A. Description
1. Calcium channel blockers decrease cardiac contractility (negative inotropic effect by relaxing smooth muscle) and the workload of the heart, thus decreasing the need for oxygen.
2. Calcium channel blockers promote vasodilation of the coronary and peripheral vessels.
3. Used for angina, dysrhythmias, or hypertension
4. Used with caution in the client with heart failure, bradycardia, or atrioventricular block

B. Side and adverse effects
1. Bradycardia
2. Hypotension
3. Reflex tachycardia as a result of hypotension
4. Headache
5. Dizziness, light-headedness
6. Fatigue
7. Peripheral edema
8. Constipation
9. Flushing of the skin
10. Changes in liver and kidney function

C. Interventions
1. Monitor vital signs.
2. Monitor for signs of heart failure.
3. Monitor liver enzyme levels.
4. Monitor kidney function tests.
5. Instruct the client not to discontinue the medication.
6. Instruct the client in how to take the pulse.

BOX 54.16 Peripheral Vasodilators

α-Adrenergic Blockers
- Doxazosin
- Prazosin
- Terazosin

Calcium Channel Blockers
- Diltiazem
- Nifedipine
- Nimodipine
- Verapamil

Hemorheological
- Pentoxifylline (increases microcirculation and tissue perfusion)

7. Instruct the client to notify the PHCP if dizziness or fainting occurs.
8. Instruct the client not to crush or chew sustained-release tablets.

XIII. Peripheral Vasodilators (Box 54.16)

A. Description
1. Peripheral vasodilators decrease peripheral resistance by exerting a direct action on the arteries or on the arteries and the veins.
2. These medications increase blood flow to the extremities and are used in peripheral vascular disorders of venous and arterial vessels.
3. Peripheral vasodilators are most effective for disorders resulting from vasospasm (Raynaud's disease).
4. These medications may decrease some symptoms of cerebral vascular insufficiency.

B. Side and adverse effects
1. Light-headedness, dizziness
2. Orthostatic hypotension
3. Tachycardia
4. Palpitations
5. Flushing
6. Gastrointestinal distress

C. Interventions
1. Monitor vital signs, especially the BP and the heart rate.
2. Monitor for orthostatic hypotension and tachycardia.
3. Monitor for signs of inadequate blood flow to the extremities, such as pallor, pain, or feeling cold.
4. Instruct the client that it may take up to 3 months for a desired therapeutic response.
5. Advise the client not to smoke, because smoking increases vasospasm.
6. Instruct the client to avoid aspirin or aspirin-like compounds unless approved by the PHCP.

Telegram & Insta: NCLEX_RN_Edu

BOX 54.17 Direct-Acting Arteriolar Vasodilators

- Diazoxide
- Fenoldopam
- Hydralazine
- Nitroglycerin
- Sodium nitroprusside

7. Instruct the client to take the medication with meals if gastrointestinal disturbances occur.
8. Instruct the client to avoid alcohol, because it may cause a hypotensive reaction.
9. Encourage the client to change positions slowly to avoid orthostatic hypotension.

XIV. Direct-Acting Arteriolar Vasodilators (Box 54.17)

A. Description
1. Direct-acting vasodilators relax the smooth muscles of the blood vessels, mainly the arteries, causing vasodilation; with vasodilation, the BP drops and sodium and water are retained, resulting in peripheral edema (diuretics may be given to decrease the edema).
2. Direct-acting vasodilators promote an increase in blood flow to the brain and kidneys.
3. These medications are used in the client with moderate to severe hypertension and for acute hypertensive emergencies.

B. Side and adverse effects
1. Hypotension
2. Reflex tachycardia caused by vasodilation and the drop in BP
3. Palpitations
4. Edema
5. Dizziness
6. Headaches
7. Nasal congestion
8. Gastrointestinal bleeding
9. Neurological symptoms
10. Confusion
11. With sodium nitroprusside, cyanide toxicity and thiocyanate toxicity can occur.

C. Interventions
1. Monitor vital signs, especially BP.
2. Sodium nitroprusside
   a. Monitor cyanide and thiocyanate levels.
   b. Protect from light because the medication decomposes.
   c. When administering, solution must be covered by a dark bag provided by the manufacturer and is stable for 24 hours.
   d. Discard if the medication is red, green, or blue.

Vasodilators cause orthostatic hypotension. Instruct the client about safety measures when taking these medications, such as when rising from a lying to a sitting or standing position slowly.

XV. Miscellaneous Vasodilator

A. Description
1. Nesiritide
   a. Recombinant version of human B-type natriuretic peptide that vasodilates arteries and veins
   b. Used for the treatment of decompensated heart failure
2. Side and adverse effects
   a. Hypotension
   b. Confusion
   c. Dizziness
   d. Dysrhythmias
3. Interventions
   a. Administer via continuous IV infusion device.
   b. Monitor BP, cardiac rhythm, urine output, and body weight.
   c. Monitor for signs of resolving heart failure.

XVI. Antidysrhythmic Medications

A. Description: Antidysrhythmic medications suppress dysrhythmias by inhibiting abnormal pathways of electrical conduction through the heart.

B. Class I antidysrhythmics are sodium channel blockers, class II are beta blockers, class III are potassium channel blockers (medications that delay repolarization), and class IV are calcium channel blockers.

C. Class IA antidysrhythmics
1. Disopyramide
2. Procainamide
3. Quinidine sulfate

D. Class IB antidysrhythmics
1. Lidocaine
2. Mexiletine hydrochloride
3. Phenytoin

E. Class IC antidysrhythmics
1. Flecainide acetate
2. Propafenone hydrochloride
3. Side and adverse effects: Class I antidysrhythmics
   a. Hypotension
   b. Heart failure
   c. Worsened or new dysrhythmias
   d. Nausea, vomiting, or diarrhea

F. Class II antidysrhythmics
1. Acebutolol
2. Esmolol
3. Propranolol
4. Metoprolol
5. Nadolol
6. Atenolol
7. Side and adverse effects: Class II antidysrhythmics
   a. Dizziness
   b. Fatigue
   c. Hypotension

Telegram & Insta: NCLEX_RN_Edu

- **d.** Bradycardia
- **e.** Heart failure
- **f.** Dysrhythmias
- **g.** Heart block
- **h.** Bronchospasms
- **i.** Gastrointestinal distress

G. Class III antidysrhythmics
1. Amiodarone
2. Dofetilide
3. Ibutilide
4. Sotalol
5. Side and adverse effects: Class III antidysrhythmics
   - **a.** Hypotension
   - **b.** Bradycardia
   - **c.** Nausea, vomiting
   - **d.** Amiodarone hydrochloride may cause pulmonary fibrosis, photosensitivity, bluish skin discoloration, corneal deposits, peripheral neuropathy, tremor, poor coordination, abnormal gait, and hypothyroidism.
   - **e.** The electrocardiogram should be monitored for clients receiving amiodarone or dofetilide, because they may prolong the QT interval, potentially leading to torsades de pointes (a ventricular tachycardia that occurs in the setting of long QT interval).

H. Class IV antidysrhythmics
1. Verapamil
2. Diltiazem
3. Side and adverse effects: Class IV antidysrhythmics
   - **a.** Dizziness
   - **b.** Hypotension
   - **c.** Bradycardia
   - **d.** Edema
   - **e.** Constipation

I. Other antidysrhythmics
1. Adenosine
2. Digoxin

J. Interventions for antidysrhythmics
1. Monitor heart rate, respiratory rate, and BP.
2. Monitor electrocardiogram.
3. Provide continuous cardiac monitoring.
4. Maintain therapeutic serum medication levels.
5. Before administering lidocaine, always check the vial label to prevent administering a form that contains epinephrine or preservatives, because these solutions are used for local anesthesia only.
6. Do not administer antidysrhythmics with food, because food may affect absorption.
7. Mexiletine may be administered with food or antacids to reduce gastrointestinal distress.
8. Always administer IV antidysrhythmics via an infusion pump.

BOX 54.18 Adrenergic Agonists

- Dobutamine
- Dopamine
- Epinephrine
- Norepinephrine

9. Monitor for signs of fluid retention such as weight gain, peripheral edema, or shortness of breath.
10. Advise the client to limit fluid and salt intake to minimize fluid retention.
11. Monitor respiratory, thyroid, and neurological functions.
12. Instruct the client to change positions slowly to minimize orthostatic hypotension.
13. Instruct the client taking amiodarone to use sunscreen and protective clothing to prevent photosensitivity reactions.
14. Encourage the client to increase fiber intake to prevent constipation.

XVII. Adrenergic Agonists (Box 54.18)

A. Dobutamine
1. Increases myocardial force and cardiac output through stimulation of β-receptors
2. Used in clients with heart failure and for clients undergoing cardiopulmonary bypass surgery

B. Dopamine
1. Increases BP and cardiac output through positive inotropic action and increases renal blood flow through its action on α- and β-receptors
2. Used to treat mild kidney failure caused by low cardiac output

C. Epinephrine
1. Used for cardiac stimulation in cardiac arrest
2. Used for bronchodilation in asthma or allergic reactions
3. Produces mydriasis
4. Produces local vasoconstriction when combined with local anesthetics and prolongs anesthetic action by decreasing blood flow to the site

D. Norepinephrine
1. Stimulates the heart in cardiac arrest
2. Vasoconstricts and increases the BP in hypotension and shock

E. Side and adverse effects
1. Dysrhythmias
2. Tachycardia
3. Angina
4. Restlessness
5. Urgency or urinary incontinence

F. Interventions
1. Monitor vital signs.
2. Monitor lung sounds.

Telegram & Insta: NCLEX_RN_Edu

3. Monitor urinary output.
4. Monitor electrocardiogram.
5. Administer the medication through a large vein.

XVIII. Antilipemic Medications

A. Description

1. Antilipemic medications reduce serum levels of cholesterol, triglycerides, or low-density lipoprotein.
2. When cholesterol, triglyceride, and low-density lipoprotein levels are elevated, the client is at increased risk for coronary artery disease.
3. In many cases, diet alone will not lower blood lipid levels; therefore, antilipemic medications will be prescribed.

B. Bile sequestrants (see Chapter 50)

1. Description
   a. Bind with acids in the intestines, which prevents reabsorption of cholesterol
   b. Should not be used as the only therapy in clients with elevated triglyceride levels because they may raise triglyceride levels
2. Side and adverse effects
   a. Constipation
   b. Gastrointestinal disturbances: Heartburn, nausea, belching, bloating
3. Interventions
   a. Cholestyramine comes in a gritty powder that must be mixed thoroughly in juice or water before administration.
   b. Monitor the client for early signs of peptic ulcer such as nausea and abdominal discomfort followed by abdominal pain and distention.
   c. Instruct the client that the medication must be taken with and followed by sufficient fluids.

C. HMG-CoA reductase inhibitors (Box 54.19)

1. Description
   a. Lovastatin is highly protein-bound and should not be administered with anticoagulants.
   b. Lovastatin should not be administered with gemfibrozil.
   c. Administer lovastatin with caution to the client taking immunosuppressive medications.
2. Side and adverse effects
   a. Nausea
   b. Diarrhea or constipation
   c. Abdominal pain or cramps
   d. Flatulence
   e. Dizziness
   f. Headache
   g. Blurred vision
   h. Rash
   i. Pruritus
   j. Elevated liver enzyme levels
   k. Muscle cramps and fatigue

BOX 54.19 HMG-CoA Reductase Inhibitors

- Atorvastatin
- Fluvastatin
- Lovastatin
- Pitavastatin
- Pravastatin
- Rosuvastatin
- Simvastatin

BOX 54.20 Other Antilipemic Medications

- Cholestyramine
- Colesevelam
- Colestipol
- Ezetimibe
- Fenofibrate
- Gemfibrozil
- Icosapent
- Lomitapide
- Nicotinic acid
- Omega-3-acid ethyl esters

3. Interventions
   a. Monitor serum liver enzyme levels.
   b. Instruct the client to have an annual eye examination, because the medications can cause cataract formation.
   c. If lovastatin is not effective in lowering the lipid level after 3 months, it should be discontinued.

! Instruct the client who is taking an antilipemic medication to report any unexplained muscular pain to the PHCP immediately.

D. Other antilipemic medications (Box 54.20)

1. Description
   a. Gemfibrozil should not be taken with anticoagulants, because they compete for protein sites; if the client is taking an anticoagulant, the anticoagulant dose should be reduced during antilipemic therapy and the INR should be monitored closely.
   b. Do not administer gemfibrozil with HMG-CoA reductase inhibitors, because it increases the risk for myositis, myalgias, and rhabdomyolysis.
   c. Fish oil supplements have been associated with a decreased risk for cardiovascular heart disease; plant stanol and sterol esters and cholestin have been associated with reducing cholesterol levels.
2. Interventions
   a. Monitor vital signs.
   b. Monitor liver enzyme levels.
   c. Monitor serum cholesterol and triglyceride levels.
   d. Instruct the client that it will take several weeks before the lipid level declines.
   e. Instruct the client to restrict intake of fats, cholesterol, carbohydrates, and alcohol.

Telegram & Insta: NCLEX_RN_Edu

f. Instruct the client to follow an exercise program.
g. Instruct the client to have an annual eye examination and to report changes in vision.
h. Instruct the client with diabetes mellitus who is taking gemfibrozil to monitor blood glucose levels regularly.
i. Instruct the client to increase fluid intake.
j. Nicotinic acid has numerous side and adverse effects, including gastrointestinal disturbances, flushing of the skin, elevated liver enzyme levels, hyperglycemia, and hyperuricemia.
k. Instruct the client that taking aspirin or nonsteroidal antiinflammatory drugs 30 minutes before nicotinic acid may assist in reducing the side effect of cutaneous flushing.
l. Instruct the client to take nicotinic acid with meals to reduce gastrointestinal discomfort.

PRACTICE QUESTIONS

1. A client with atrial fibrillation is receiving a continuous heparin infusion at 1000 units/hr. Which result would indicate to the nurse that the client is receiving a therapeutic dose?
1. Prothrombin time of 12.5 seconds
2. Activated partial thromboplastin time of 28 seconds
3. Activated partial thromboplastin time of 60 seconds
4. Activated partial thromboplastin time longer than 120 seconds

2. The nurse provides discharge instructions to a client with atrial fibrillation who is taking warfarin sodium. Which statement by the client reflects the **need for further teaching**?
1. "I will avoid alcohol consumption."
2. "I will take coated aspirin for my headaches."
3. "I will take my pills every day at the same time."
4. "I have already called my family to pick up a MedicAlert bracelet."

3. A client who is receiving digoxin daily has a serum potassium level of 3 mEq/L (3 mmol/L) and reports anorexia. The cardiologist prescribes a serum digoxin level to be done. Which level would the nurse recognize as being outside of the therapeutic range?
1. 0.5 ng/mL (0.63 nmol/L)
2. 0.8 ng/mL (1.02 nmol/L)
3. 0.9 ng/mL (1.14 nmol/L)
4. 2.2 ng/mL (2.8 nmol/L)

4. A client is being treated with procainamide for a cardiac dysrhythmia. Following intravenous administration of the medication, the client complains of dizziness. Which intervention would the nurse implement **first**?
1. Obtain a 12-lead electrocardiogram.
2. Check the client's fingerstick blood glucose level.
3. Auscultate the client's apical pulse and blood pressure.
4. Measure the QRS interval duration on the rhythm strip.

5. The nurse is monitoring a client with hypertension who is taking propranolol. Which assessment finding indicates a potential adverse complication associated with this medication?
1. Report of infrequent insomnia
2. Development of expiratory wheezes
3. A baseline blood pressure of 150/80 mm Hg followed by a blood pressure of 138/72 mm Hg after two doses of the medication
4. A baseline resting heart rate of 88 beats per minute followed by a resting heart rate of 72 beats per minute after two doses of the medication

6. A client with valvular heart disease who has a clot in the right atrium is receiving a heparin sodium infusion at 1000 units/hr and warfarin sodium 7.5 mg at 1600 daily. The morning laboratory results are as follows: activated partial thromboplastin time (aPTT), 32 seconds; international normalized ratio (INR), 1.3. Which action would the nurse take based on the client's laboratory results?
1. Collaborate with the PHCP to discontinue the heparin infusion and administer the warfarin sodium as prescribed.
2. Collaborate with the PHCP to obtain a prescription to increase the heparin infusion and continue the warfarin sodium as prescribed.
3. Collaborate with the PHCP to withhold the warfarin sodium since the client is receiving a heparin infusion and the aPTT is within the therapeutic range.
4. Collaborate with the PHCP to continue the heparin infusion at the same rate and to discuss use of dabigatran etexilate in place of warfarin sodium.

7. A client is diagnosed with an ST segment elevation myocardial infarction (STEMI) and is receiving a tissue plasminogen activator, alteplase. Which action is a **priority** nursing intervention?
1. Monitor for kidney failure.
2. Monitor psychosocial status.
3. Monitor for signs of bleeding.
4. Have heparin sodium available.

Telegram & Insta: NCLEX_RN_Edu

8. The nurse is monitoring a client for adverse effects of medications. Which findings are characteristic of adverse effects of hydrochlorothiazide? **Select all that apply.**
   - ❑ 1. Sulfa allergy
   - ❑ 2. Osteoporosis
   - ❑ 3. Hypokalemia
   - ❑ 4. Hypouricemia
   - ❑ 5. Hyperglycemia
   - ❑ 6. Hypercalcemia

9. The home health care nurse is visiting a client with coronary artery disease with elevated triglyceride levels and a serum cholesterol level of 398 mg/dL (10 mmol/L). The client is taking cholestyramine, and the nurse teaches the client about the medication. Which statement by the client indicates the **need for further teaching**?
   1. "Constipation and bloating might be a problem."
   2. "I'll continue to watch my diet and reduce my fats."
   3. "Walking a mile each day will help the whole process."
   4. "I'll continue my nicotinic acid from the health food store."

10. The nurse is monitoring a client with heart failure who is taking digoxin. Which findings are characteristic of digoxin toxicity? **Select all that apply.**
    - ❑ 1. Tremors
    - ❑ 2. Diarrhea
    - ❑ 3. Irritability
    - ❑ 4. Blurred vision
    - ❑ 5. Nausea and vomiting

11. Prior to administering a client's daily dose of digoxin to treat heart failure, the nurse reviews the client's laboratory data and notes the following results: serum calcium, 9.8 mg/dL (2.45 mmol/L); serum magnesium, 1.0 mEq/L (0.4 mmol/L); serum potassium, 4.1 mEq/L (4.1 mmol/L); serum creatinine, 0.9 mg/dL (79.5 mcmol/L). Which result would alert the nurse that the client is at risk for digoxin toxicity?
    1. Serum calcium level
    2. Serum potassium level
    3. Serum creatinine level
    4. Serum magnesium level

12. The nurse administered intravenous bumetanide to a client being treated for heart failure. Which outcome indicates that the medication has achieved the expected effect?
    1. Cough becomes productive of frothy pink sputum.
    2. Urine output increases from 10 mL/hr to greater than 50 mL hourly.
    3. The serum potassium level changes from 3.8 to 3.1 mEq/L (3.8 to 3.1 mmol/L).
    4. B-type natriuretic peptide (BNP) factor increases from 200 to 262 ng/mL (200 to 262 mcg/L).

13. Intravenous heparin therapy is prescribed for a client with atrial fibrillation. While implementing this prescription, the nurse ensures that which medication is available on the nursing unit?
    1. Vitamin K
    2. Protamine sulfate
    3. Potassium chloride
    4. Aminocaproic acid

14. A client receiving thrombolytic therapy with a continuous infusion of alteplase suddenly becomes extremely anxious and reports itching. The nurse hears stridor and notes generalized urticaria and hypotension. Which interventions would the nurse take? **Select all that apply.**
    - ❑ 1. Stop the infusion.
    - ❑ 2. Raise the head of the bed.
    - ❑ 3. Administer protamine sulfate.
    - ❑ 4. Administer diphenhydramine.
    - ❑ 5. Call for the Rapid Response Team (RRT).

15. The nurse would report which assessment finding to the primary health care provider (PHCP) before initiating thrombolytic therapy in a client with pulmonary embolism?
    1. Adventitious breath sounds
    2. Temperature of 99.4° F (37.4° C) orally
    3. Blood pressure of 198/110 mm Hg
    4. Respiratory rate of 28 breaths per minute

16. The nurse provides instructions to the client about nicotinic acid prescribed for hyperlipidemia. Which statement by the client indicates understanding of the instructions?
    1. "The medication needs to be taken with meals to decrease flushing."
    2. "I don't need to stop drinking alcohol when taking nicotinic acid."
    3. "Clay-colored stools are a common side effect and are not a concern."
    4. "Ibuprofen taken 30 minutes before the nicotinic acid may decrease the flushing."

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 3

Rationale: Common laboratory ranges for activated partial thromboplastin time (aPTT) are 30 to 40 seconds. Because the aPTT should be 1.5 to 2.5 times the normal value, the client's aPTT would be considered therapeutic if it was 60 seconds. Prothrombin time assesses response to warfarin therapy.

Test-Taking Strategy: Focus on the **subject,** the therapeutic effect of heparin. Prothrombin time is eliminated because it assesses response to warfarin therapy. The aPTT of 28 seconds is eliminated because this result indicates that the client is receiving no therapeutic effect from the continuous heparin infusion. Finally, the aPTT greater than 120 seconds can be eliminated because this value is beyond the therapeutic range and the client is at risk for bleeding.

References: Gahart, B., Nazareno, A., & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. pp. 703-704; Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 34, 723.

2. *Answer:* 2

Rationale: Aspirin-containing products need to be avoided when a client is taking this medication. Alcohol consumption needs to be avoided by a client taking warfarin sodium. Taking the prescribed medication at the same time each day increases client compliance. The MedicAlert bracelet provides health care personnel with emergency information.

Test-Taking Strategy: Note the **strategic words**, *need for further teaching.* These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Recalling that warfarin is an anticoagulant and that coated aspirin is an aspirin-containing product will direct you to the correct option.

Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. p. 1246.

3. *Answer:* 4

Rationale: The optimal therapeutic range for digoxin is 0.5 to 2.0 ng/mL (0.63 to 2.56 nmol/L). If the client is experiencing symptoms such as anorexia and is experiencing hypokalemia as evidenced by a low potassium level, digoxin toxicity is a concern. Therefore, option 4 is correct because it is outside of the therapeutic level and elevated.

Test-Taking Strategy: Focus on the **subject,** a digoxin level outside of the therapeutic range. Additionally, **determine if an abnormality exists.** Note that the client is experiencing anorexia and has a low serum potassium level. Therefore, it is best to select the option that identifies the highest level. Recall that in hypokalemia, the client is at greater risk for digoxin toxicity.

Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 398.

4. *Answer:* 3

Rationale: Signs of toxicity from procainamide include confusion, dizziness, drowsiness, decreased urination, nausea, vomiting, and tachydysrhythmias. If the client complains of dizziness, the nurse would assess the vital signs first. Although measuring the QRS duration on the rhythm strip and obtaining a 12-lead electrocardiogram may be interventions, these would be done after the vital signs are taken. Dizziness directly following the procainamide indicates that the medication was the likely cause and needs to be addressed before assessing for other possible causes such as hypoglycemia.

Test-Taking Strategy: Note the **strategic word**, *first.* Also use the **steps of the nursing process** to answer correctly. Remember to always assess the client first, not the monitoring devices. Therefore, auscultating the apical pulse and taking the blood pressure are the first actions.

Reference: Gahart, B., Nazareno, A. & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. p. 1134.

5. *Answer:* 2

Rationale: Audible expiratory wheezes may indicate a serious adverse reaction, bronchospasm. Beta blockers may induce this reaction, particularly in clients with chronic obstructive pulmonary disease or asthma. Normal decreases in blood pressure and heart rate are expected. Insomnia is a frequent mild side effect and need to be monitored.

Test-Taking Strategy: Focus on the **subject,** a potential adverse complication. Eliminate options indicating a decrease in blood pressure and a decrease in heart rate first, because these are expected effects from the medication. Next, focusing on the **subject** will direct you to the correct option.

Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. pp. 969-970.

6. *Answer:* 2

Rationale: When a client is receiving warfarin for clot prevention due to atrial fibrillation, an INR of 2 to 3 is appropriate for most clients. Until the INR has achieved a therapeutic range, the client should be maintained on a continuous heparin infusion with the aPTT ranging between 60 and 80 seconds. Therefore, the nurse would collaborate with the HCP to obtain a prescription to increase the heparin infusion and to administer the warfarin as prescribed.

Test-Taking Strategy: Focus on the **subject,** laboratory result analysis related to these medications. First, eliminate the option that indicates to discuss use of dabigatran etexilate, recalling that it is contraindicated for use in atrial fibrillation associated with valvular heart disease. Next, recall that if the warfarin sodium has achieved the therapeutic range for the INR for clot prevention in atrial fibrillation, the heparin infusion is no longer necessary. This will help you eliminate the option that indicates to withhold the warfarin sodium because the INR is not therapeutic. Last, keep in mind that if both the aPTT and the INR are not within therapeutic range, the client is left unprotected from clot formation.

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 614, 629-631.

7. *Answer:* 3

Rationale: Tissue plasminogen activator is a thrombolytic. Hemorrhage is a complication of any type of thrombolytic medication. The client is monitored for bleeding. Monitoring

Telegram & Insta: NCLEX_RN_Edu

for renal failure and monitoring the client's psychosocial status are important but are not the most critical interventions. Heparin may be administered after thrombolytic therapy, but the question is not asking about follow-up medications.
Test-Taking Strategy: Note the **strategic word**, *priority*. Remember that bleeding is a priority for thrombolytic medications.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 632, 626-627.

8. *Answer:* 1, 3, 5, 6
Rationale: Thiazide diuretics such as hydrochlorothiazide are sulfa-based medications, and a client with a sulfa allergy is at risk for an allergic reaction. Also, clients are at risk for hypokalemia, hyperglycemia, hypercalcemia, hyperlipidemia, and hyperuricemia.
Test-Taking Strategy: Focus on the **subject,** a concern related to administration of hydrochlorothiazide. Recall that the chemical makeup of thiazide diuretics carries a sulfa ring.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 464-465, 470.

9. *Answer:* 4
Rationale: Nicotinic acid, even an over-the-counter form, needs to be avoided because it may lead to liver abnormalities. All lipid-lowering medications also can cause liver abnormalities, so a combination of nicotinic acid and cholestyramine resin needs to be avoided. Constipation and bloating are the two most common adverse effects. Walking and the reduction of fats in the diet are therapeutic measures to reduce cholesterol and triglyceride levels.
Test-Taking Strategy: Note the **strategic words**, *need for further teaching*. These words indicate a **negative event query** and ask you to select an option that is an incorrect statement. Remembering that over-the-counter medications need to be avoided when a client is taking a prescription medication will direct you to the correct option.
References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 584, 590; Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 435-436.

10. *Answer:* 2, 4, 5
Rationale: Digoxin is a cardiac glycoside. The risk of toxicity can occur with the use of this medication. Toxicity can lead to life-threatening events and the nurse needs to monitor the client closely for signs of toxicity. Early signs of toxicity include gastrointestinal manifestations such as anorexia, nausea, vomiting, and diarrhea. Subsequent manifestations include headache; visual disturbances such as diplopia, blurred vision, yellow-green halos, and photophobia; drowsiness; fatigue; and weakness. Cardiac rhythm abnormalities can also occur. The nurse also monitors the digoxin level. The optimal therapeutic range for digoxin is 0.5 to 2.0 ng/mL (0.63 to 2.56 nmol/L).
Test-Taking Strategy: Focus on the **subject,** digoxin toxicity. Specific knowledge regarding the characteristics of digoxin toxicity is needed to answer this question. Recall that the early signs are gastrointestinal manifestations. Next, recall that visual disturbances can occur.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 378.

11. *Answer:* 4
Rationale: An increased risk of toxicity exists in clients with hypercalcemia, hypokalemia, hypomagnesemia, hypothyroidism, and impaired renal function. The calcium, creatinine, and potassium levels are all within normal limits. The normal range for magnesium is 1.8–2.6 mEq/L (0.74–1.07 mmol/L), and the results in the laboratory data are reflective of hypomagnesemia.
Test-Taking Strategy: Focus on the **subject,** the laboratory result that places the client at risk for digoxin toxicity. Recalling the normal laboratory values for each electrolyte identified in the options will assist in answering correctly.
Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. p. 344.

12. *Answer:* 2
Rationale: Bumetanide is a diuretic and expected outcomes include increased urine output, decreased crackles, and decreased weight. Potassium loss is a side effect rather than an expected effect of the diuretic. Frothy pink sputum indicates progression to pulmonary edema. A BNP greater than 100 ng/mL (100 mcg/L) is indicative of heart failure; thus, a rise from a previous level indicates worsening of the condition.
Test-Taking Strategy: Focus on the **subject,** assessment findings indicative of the expected effect of bumetanide. Keep in mind when answering this question that an expected effect of a medication refers to a positive outcome versus a side or adverse effect. This will help you eliminate the option that refers to the potassium loss.
Reference: Gahart, B., Nazareno, A., & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. pp. 217-218.

13. *Answer:* 2
Rationale: The antidote to heparin is protamine sulfate; it needs to be readily available for use if excessive bleeding or hemorrhage occurs. Vitamin K is an antidote for warfarin sodium. Potassium chloride is administered for a potassium deficit. Aminocaproic acid is the antidote for thrombolytic therapy.
Test-Taking Strategy: Focus on the **subject,** the antidote for heparin. Knowledge regarding the various antidotes is needed to answer this question. Remember that the antidote to heparin is protamine sulfate.
Reference: Gahart, B., Nazareno, A., & Ortega, M. (2021). *Gahart's 2021 intravenous medications: A handbook for nurses and health professionals.* (37th ed.). St. Louis: Elsevier. p. 708.

14. *Answer:* 1, 4, 5
Rationale: The client is experiencing an anaphylactic reaction. Therefore, the priority action is to stop the infusion and notify the RRT. The client may be treated with antihistamines. Raising the head of the bed would not be helpful, as that may

Telegram & Insta: NCLEX_RN_Edu

exacerbate the hypotension. Protamine sulfate is the antidote for heparin, so it is not useful for a client receiving alteplase.
Test-Taking Strategy: Note the **strategic word**, *priority.* Recall that an allergic reaction and possible anaphylaxis are risks associated with alteplase therapy. Also, focusing on the signs and symptoms in the question will assist in answering correctly. When a severe allergic reaction occurs, the offending substance should be stopped, and lifesaving treatment should begin.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 351.

15. *Answer:* 3
Rationale: Thrombolytic therapy is contraindicated in severe uncontrolled hypertension because of the risk of cerebral hemorrhage. Therefore, the nurse would report the results of the blood pressure to the PHCP before initiating therapy.
Test-Taking Strategy: Focus on the **subject,** a contraindication for the use of thrombolytic therapy. Adventitious breath sounds, temperature of 99.4° F (37.4° C), and respiratory rate of 28 breaths per minute may be present in the client with pulmonary embolism but are not necessarily signs that warrant reporting before thrombolytic therapy is initiated.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 590-591, 761.

16. *Answer:* 4
Rationale: Flushing is an adverse effect of this medication. Aspirin or a nonsteroidal antiinflammatory drug, as prescribed, can be taken 30 minutes prior to taking the medication to decrease flushing. Alcohol consumption needs to be avoided because it will enhance this effect. The medication needs to be taken with meals to decrease gastrointestinal upset; however, taking the medication with meals has no effect on the flushing. Clay-colored stools are a sign of hepatic dysfunction and need to be reported to the primary health care provider (PHCP) immediately.
Test-Taking Strategy: Focus on the **subject,** client understanding of the medication. Alcohol must be abstained from, so this option can be eliminated. Taking the medication with meals helps decrease the gastrointestinal symptoms rather than flushing. Clay-colored stools are a sign of hepatic dysfunction and need to be reported to the PHCP immediately.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p. 436.

UNIT XIII

Renal and Urinary Problems of the Adult Client

Pyramid to Success

Pyramid Points focus on acute kidney injury and chronic kidney disease, dialysis procedures, urinary diversions, and postoperative care following urinary or renal surgery. Medical conditions and diagnostic tests that place the client at risk for acute kidney injury are addressed. Major problems associated with kidney failure and the rationale for the prescribed treatment modalities are a focus. The complications associated with hemodialysis and peritoneal dialysis, the specific assessment data related to complications, and the expected treatment are noted. The care of a peritoneal catheter and hemodialysis access devices, the complications associated with these access devices, and the appropriate nursing interventions if a complication is suspected are reviewed. Assessment data indicating rejection following kidney transplantation is emphasized.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Consulting with the interprofessional health care team
Identifying the guidelines related to kidney organ donation
Maintaining asepsis related to wound care and dialysis access devices
Maintaining confidentiality related to the renal disorder
Maintaining standard and other precautions related to care for the client
Preventing injury related to complications of the disorder
Prioritizing hypotheses based on client needs
Upholding client rights
Verifying that informed consent related to diagnostic and surgical procedures has been obtained

Health Promotion and Maintenance

Generating solutions for a home care plan for the client
Performing urinary and renal physical assessment techniques
Providing client instructions regarding prescribed treatments related to the urinary or renal problem
Providing client instructions on prevention of a urinary or renal problem
Recognizing cues in the client that increase the risk of developing renal problems

Psychosocial Integrity

Assisting the client to use appropriate coping mechanisms
Discussing body image disturbances
Discussing the loss of renal function
Identifying cultural, religious, and spiritual influences on health
Identifying grief and loss and end-of-life issues
Identifying support systems and appropriate community resources

Physiological Integrity

Administering medications and other measures for the treatment of renal or urinary problems
Analyzing assessment findings to determine client status
Ensuring elimination measures
Evaluating the effectiveness of the therapeutic regimen
Informing the client about diagnostic tests and laboratory results
Monitoring for fluid and electrolyte imbalances and acid-base disorders
Obtaining assessment data indicating rejection of kidney transplant
Preventing complications arising as a result of dialysis
Providing care related to hemodialysis and peritoneal dialysis and dialysis access devices
Recognizing cues that indicate a complication of a urinary or renal problem
Taking action in an emergency situation
Teaching the client about the prescribed nutrition and fluid measures

CHAPTER 55

Renal and Urinary Problems

Contributor: Erica Shae Lee, MSN-Ed, RN

PRIORITY CONCEPTS **Fluids and Electrolytes; Elimination**

I. Anatomy and Physiology

A. Kidney anatomy

1. Each person has two kidneys, which are located behind the peritoneum; they are attached at the level of the last thoracic and first three lumbar vertebrae, on the right and left sides.
2. The kidneys are enclosed in the renal capsule.
3. The renal cortex is the outer layer of the renal capsule, which contains blood-filtering mechanisms (glomeruli).
4. The renal medulla is the inner region, which contains the renal pyramids and renal tubules.
5. Together, the renal cortex, pyramids, and medulla constitute the parenchyma.
6. Nephrons
   - **a.** Located within the parenchyma
   - **b.** Composed of glomerulus and tubules
   - **c.** Selectively secretes and reabsorbs ions and filtrates, including fluid, wastes, electrolytes, acids, and bases

The nephrons are the functional units of the kidney.

7. Glomerulus
   - **a.** Each nephron contains tufts of capillaries, which filter large plasma proteins and blood cells.
   - **b.** Blood flows into the glomerular capillaries from the afferent arteriole and flows out of the glomerular capillaries into the efferent arteriole.
8. Bowman's capsule
   - **a.** Thin double-walled capsule that surrounds the glomerulus
   - **b.** Fluid and particles from the blood such as electrolytes, glucose, amino acids, and metabolic waste (glomerular filtrate) are filtered through the glomerular membrane into a fluid-filled space in Bowman's capsule (Bowman's space) and then enter the proximal convoluted tubule (PCT).
9. Tubules
   - **a.** The tubules include the PCT, the loop of Henle, and the distal convoluted tubule (DCT).
   - **b.** The PCT receives filtrate from the glomerular capsule and reabsorbs water and electrolytes through active and passive transport.
   - **c.** The descending loop of Henle passively reabsorbs water from the filtrate.
   - **d.** The ascending loop of Henle passively reabsorbs sodium and chloride from the filtrate and helps maintain osmolality.
   - **e.** The DCT actively and passively removes sodium and water.
   - **f.** The filtered fluid is converted to urine in the tubules; then the urine moves to the pelvis of the kidney.
   - **g.** The urine flows from the pelvis of the kidneys through the ureters and empties into the bladder.

B. Functions of kidneys

1. Maintain acid–base balance
2. Excrete end products of body metabolism
3. Control fluid and electrolyte balance
4. Excrete bacterial toxins, water-soluble medications, and medication metabolites
5. Secrete renin to regulate the blood pressure (BP) and erythropoietin to stimulate the bone marrow to produce red blood cells
6. Synthesize vitamin D for calcium absorption and regulation of the parathyroid hormones

Telegram & Insta: NCLEX_RN_Edu

C. Urine production
   1. As fluid flows through the tubules, water, electrolytes, and solutes are reabsorbed, and other solutes such as creatinine, hydrogen ions, and potassium are secreted.
   2. Water and solutes that are not reabsorbed become urine.
   3. The process of selective reabsorption determines the amount of water and solutes to be secreted.

D. Homeostasis of water
   1. Antidiuretic hormone (ADH) is primarily responsible for the reabsorption of water by the kidneys.
   2. ADH is produced by the hypothalamus and secreted from the posterior lobe of the pituitary gland.
   3. Secretion of ADH is stimulated by dehydration or high sodium intake and by a decrease in blood volume.
   4. ADH makes the distal convoluted tubules and collecting duct permeable to water.
   5. Water is drawn out of the tubules by osmosis and returns to the blood; concentrated urine remains in the tubule to be excreted.
   6. When ADH is lacking, the client develops diabetes insipidus (DI).
   7. Clients with DI produce large amounts of dilute urine; treatment is necessary because the client cannot drink sufficient water to survive.

E. Homeostasis of sodium
   1. When the amount of sodium increases, extra water is retained to preserve osmotic pressure.
   2. An increase in sodium and water produces an increase in blood volume and BP.
   3. When the BP increases, glomerular filtration increases, and extra water and sodium are lost; blood volume is reduced, returning the BP to normal.
   4. Reabsorption of sodium in the distal convoluted tubules is controlled by the renin-angiotensin system.
   5. Renin, an enzyme, is released from the nephron when the BP or fluid concentration in the distal convoluted tubule is low.
   6. Renin catalyzes the splitting of angiotensin I from angiotensinogen; angiotensin I converts to angiotensin II as blood flows through the lung.
   7. Angiotensin II, a potent vasoconstrictor, stimulates the secretion of aldosterone.
   8. Aldosterone stimulates the distal convoluted tubules to reabsorb sodium and secrete potassium.
   9. The additional sodium increases water reabsorption and increases blood volume and BP, returning the BP to normal; the stimulus for the secretion of renin then is removed.

F. Homeostasis of potassium
   1. Increases in the serum potassium level stimulate the secretion of aldosterone.
   2. Aldosterone stimulates the distal convoluted tubules to secrete potassium; this action returns the serum potassium concentration to normal.

G. Homeostasis of acidity (pH)
   1. Blood pH is controlled by maintaining the concentration of buffer systems.
   2. Carbonic acid and sodium bicarbonate form the most important buffers for neutralizing acids in the plasma.
   3. The concentration of carbonic acid is controlled by the respiratory system.
   4. The concentration of sodium bicarbonate is controlled by the kidneys.
   5. Normal arterial pH is 7.35 to 7.45, maintained by keeping the ratio of concentrations of sodium bicarbonate to carbon dioxide constant at 20:1.
   6. Strong acids are neutralized by sodium bicarbonate to produce carbonic acid and the sodium salts of the strong acid; this process quickly restores the ratio and thus blood pH.
   7. The carbonic acid dissociates into carbon dioxide and water; because the concentration of carbon dioxide is maintained at a constant level by the respiratory system, the excess carbonic acid is rapidly excreted.
   8. Sodium combined with the strong acid is actively reabsorbed in the distal convoluted tubules in exchange for hydrogen or potassium ions. The strong acid is neutralized by ammonia and is excreted as ammonia or potassium salts.

H. Adrenal glands (see Chapter 47 for information about the adrenal glands)
   1. One adrenal gland is on top of each kidney.
   2. The adrenal glands influence BP and sodium and water retention.

I. Bladder
   1. The bladder detrusor muscle, composed of smooth muscle, distends during bladder filling and contracts during bladder emptying.
   2. The ureterovesical sphincter prevents reflux of urine from the bladder to the ureter.
   3. The total bladder capacity is 1 L; normal adult urine output is 1500 mL/day.

J. Prostate gland
   1. The prostate gland surrounds the urethra.
   2. The prostate gland contains a duct that opens into the prostatic portion of the urethra and secretes the alkaline portion of seminal fluid, which protects sperm.

K. Risk factors associated with renal problems (Box 55.1)

II. Diagnostic Tests

A. See Chapter 10 and Box 55.2 for information regarding normal values for renal function studies.

B. Determination of serum creatinine level
   1. Description: A test that measures the amount of creatinine in the serum. Creatinine is an end product of protein and muscle metabolism.

Telegram & Insta: NCLEX_RN_Edu

BOX 55.1 Risk Factors Associated with Renal Problems

- Advanced age
- Chemical or environmental toxin exposure, smoking
- Contact sports
- Diabetes mellitus, obesity, hypertension
- Family history of renal disease
- Frequent urinary tract infections
- Heart failure
- High-sodium diet
- Medications
- Polycystic kidney disease
- Trauma
- Urolithiasis or nephrolithiasis

BOX 55.2 Normal Renal Function Values

- Blood urea nitrogen (BUN) level, 10 to 20 mg/dL (3.6 to 7.1 mmol/L)
- Serum creatinine level, 0.6 to 1.2 mg/dL (53 to 106 mcmol/L) for males and 0.5 to 1.1 mg/dL (44 to 97 mcmol/L) for females
- BUN/creatinine ratio, 6 to 25

TABLE 55.1 Normal Urinalysis Values

Color	Amber yellow
Odor	Specific aromatic odor, similar to ammonia
pH	4.0-8.0 (4.0-8.0)
Osmolality	300-1300 mOsm/kg (300-1300 mmol/kg)
Specific gravity	1.003-1.030
Glucose	Negative
Ketones	Negative
Protein	Negative
Bilirubin	Negative
Casts	Negative
Bacteria	None or <1000/mL
Hemoglobin	Negative
Myoglobin	Negative
Culture for organisms	Negative

Pagana, K., Pagana, T., & Pagana, T.N. (2021). *Mosby's diagnostic and laboratory test reference*. (15th ed.). St. Louis: Elsevier. pp. 933, 936-937; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management*. (9th ed.). St. Louis: Elsevier. p. 649.

2. Analysis
   a. Creatinine level reflects the glomerular filtration rate.
   b. Kidney disease is the only pathological condition that increases the serum creatinine level.
   c. Serum creatinine level increases only when at least 50% of renal function is lost.

C. Determination of blood urea nitrogen (BUN) level
1. Description: A serum test that measures the amount of nitrogenous urea, a byproduct of protein metabolism in the liver
2. Analysis
   a. BUN levels indicate the extent of renal clearance of urea nitrogenous waste products.
   b. An elevation does not always mean that renal disease is present.
   c. Some factors that can elevate the BUN level include dehydration, poor renal perfusion, intake of a high-protein diet, infection, stress, corticosteroid use, gastrointestinal (GI) bleeding, and factors that cause muscle breakdown.

D. BUN/creatinine ratio
1. The BUN level is divided by the creatinine level to obtain the ratio.
2. When the BUN and serum creatinine levels increase at the same rate, the ratio of BUN to creatinine remains constant.
3. Elevated serum creatinine and BUN levels suggest renal dysfunction.
4. A decreased BUN/creatinine ratio occurs with fluid volume deficit, obstructive uropathy, catabolic state, and a high-protein diet.
5. An increased BUN/creatinine ratio occurs with fluid volume excess.

E. Urinalysis
1. Description: A urine test for evaluation of the renal system and renal disease (Table 55.1)
2. Interventions
   a. Wash perineal area and use a clean container for collection.
   b. Obtain 10 to 15 mL of the first morning voiding if possible.
   c. Refrigerating samples may alter the specific gravity.
   d. If the client is menstruating, note this on the laboratory requisition form.

F. A 24-hour urine collection
1. Check with the laboratory about specific instructions for the client to follow, such as dietary or medication restrictions.
2. Instruct the client about the urine collection.
3. At the start time, instruct the client to void and discard that sample.
4. Collect all urine for the prescribed time (24 hours).
5. Keep the urine specimen on ice or refrigerated, and check with the laboratory regarding adding a preservative to the specimen during collection.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

6. At the end of the prescribed time, instruct the client to empty the bladder and add that urine to the collection container.

G. Specific gravity determination
   1. Description: A urine test that measures the ability of the kidneys to concentrate urine
   2. Interventions
      a. Specific gravity can be measured by a multiple-test dipstick method (most common method), refractometer (an instrument used in the laboratory setting), or urinometer (least accurate method).
      b. Factors that interfere with an accurate reading include radiopaque contrast agents, glucose, and proteins.
      c. Cold specimens may produce a false high reading.
      d. Normal random reference interval is 1.003 to 1.030 (may vary depending on the laboratory).
      e. An increase in specific gravity (more concentrated urine) occurs with insufficient fluid intake, decreased renal perfusion, or increased ADH.
      f. A decrease in specific gravity (less concentrated urine) occurs with increased fluid intake or diabetes insipidus; it may also indicate renal disease or the kidneys' inability to concentrate urine.

H. Urine culture and sensitivity testing
   1. Description: A urine test that identifies the presence of microorganisms (culture) and determines the specific antibiotics to treat the existing microorganism (sensitivity) appropriately
   2. Interventions
      a. Clean the perineal area and urinary meatus with a bacteriostatic solution.
      b. Collect the midstream sample in a sterile container (clean catch specimen); if the client is unable to obtain a clean catch specimen, a specimen obtained by straight catheterization may be prescribed.
      c. Send the collected specimen to the laboratory immediately.
      d. Identify any sources of potential contaminants during the collection of the specimen, such as the hands, skin, clothing, hair, or vaginal or rectal secretions; if contamination occurs, the specimen is discarded and a new specimen needs to be collected. Urine from the client who drank a very large amount of fluids may be too dilute to provide a positive culture.

I. Creatinine clearance test
   1. Description
      a. The creatinine clearance test evaluates how well the kidneys remove creatinine from the blood, and is an estimate of glomerular filtration rate (GFR).
      b. The test includes obtaining a blood sample and timed urine specimens.
      c. Blood is drawn when the urine specimen collection is complete.
      d. The urine specimen for the creatinine clearance is usually collected for 24 hours, but shorter periods such as 8 or 12 hours could be prescribed.

The creatinine clearance test provides the best estimate of the GFR; the normal GFR is 125 mL per minute in a young adult. The GFR decreases with age (10% for each decade). By age 65 years the GFR is approximately 65 mL per minute.

   2. Interventions
      a. Encourage fluids before and during the test.
      b. Instruct the client to avoid caffeinated beverages during testing.
      c. Check with the primary health care provider (PHCP) regarding the administration of any prescribed medications during testing.
      d. Instruct the client about the urine collection.
      e. At the start time, ask the client to void (or empty the tubing and drainage bag if the client has a urinary catheter) and discard the first sample.
      f. Collect all urine for the prescribed time.
      g. Keep the urine specimen on ice or refrigerated and check with the laboratory regarding adding a preservative to the specimen during collection.
      h. At the end of the prescribed time, ask the client to empty the bladder (or empty the tubing and drainage bag if the client has a urinary catheter), and add that final urine to the collection container.
      i. Send the labeled urine specimen to the laboratory.
      j. Document specimen collection, time started and completed, and pertinent assessments.

J. KUB (kidneys, ureters, and bladder) radiography
   1. Description: An x-ray of the urinary system and adjacent structures to detect urinary calculi
   2. Interventions: No specific preparation is necessary.

K. Bladder ultrasonography (bladder scanning)
   1. Bladder ultrasonography is a noninvasive method for measuring the volume of urine in the bladder.
   2. Bladder ultrasonography may be performed to evaluate urinary frequency, inability to urinate, or amount of residual urine (the amount of urine remaining in the bladder after voiding).

L. Intravenous urography
   1. Description: An x-ray procedure in which an intravenous (IV) injection of a radiopaque dye is used to visualize and identify abnormalities in the renal system

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Preprocedure interventions
   a. Verify that an **informed consent** was obtained.
   b. Assess the client for allergies to iodine, seafood, and radiopaque dyes and for contraindications for the test, including a positive pregnancy test; cautions include medical history of asthma, significant cardiac disease, and renal insufficiency.
   c. Withhold food and fluids for the time prescribed.
   d. Administer laxatives if prescribed.
   e. Inform the client about possible throat irritation, flushing of the face, warmth, or a salty or metallic taste during the test.
3. Postprocedure interventions
   a. Monitor vital signs.
   b. Instruct the client to drink at least 1 L of fluid unless contraindicated.
   c. Monitor urinary output.
   d. Monitor for signs of a possible allergic reaction to the dye used during the test, and instruct the client to notify the PHCP if any signs of an allergic reaction occur.
   e. Contrast dye is potentially damaging to kidneys; the risk is greater in older clients and those experiencing dehydration.

The dye (contrast media) used in IV urography may be nephrotoxic; therefore, encourage increased fluids unless contraindicated and monitor urinary output. Preprocedure BUN and creatinine levels may be assessed on a client undergoing a procedure in which dye might be injected. The PHCP may institute precautionary measures to prevent AKI or use smaller amounts of the dye.

M. Renography (kidney scan)
1. Description: An IV injection of a radioisotope for visual imaging of renal blood flow, glomerular filtration, tubular function, and excretion
2. Preprocedure interventions
   a. Verify that an informed consent was obtained.
   b. Assess for allergies.
   c. Inform the client that the test requires no dietary or activity restrictions.
   d. Instruct the client to remain motionless during the test and that imaging may be repeated at various intervals before the test is complete.
3. Postprocedure interventions
   a. Encourage fluid intake unless contraindicated.
   b. Assess the client for signs of an allergic reaction.
   c. The radioisotope is eliminated in 24 hours; wear gloves for excretion precautions.
   d. Follow standard precautions when caring for incontinent clients, and double-bag client linens per agency policy.
   e. If captopril was administered during the procedure, the client's BP should be checked frequently.

N. Cystoscopy and biopsy of the bladder
1. Description: The bladder mucosa is examined for inflammation, calculi, or tumors by means of a cystoscope; a sample for biopsy may be obtained.
2. Preprocedure interventions
   a. Verify that an informed consent was obtained.
   b. If a biopsy is planned, withhold food and fluids for the time prescribed.
   c. If a cystoscopy alone is planned, no special preparation is necessary, and the procedure may be performed in the PHCP's office; postprocedure interventions include increasing fluid intake.
3. Postprocedure interventions following biopsy
   a. Monitor vital signs.
   b. Increase fluid intake as prescribed.
   c. Monitor intake and output and assess urine characteristics.
   d. Encourage deep-breathing exercises to relieve bladder spasms, and administer analgesics as prescribed.
   e. Administer sitz or tub baths for back and abdominal pain if prescribed.
   f. Note that leg cramps are common because of the lithotomy position maintained during the procedure.
   g. Inform the client that burning on urination, pink-tinged or tea-colored urine, and urinary frequency are common after cystoscopy and resolve in a few days.
   h. Monitor for bright red urine or clots, and notify the PHCP if a fever occurs; an increase in white blood cell (WBC) count suggests infection.

O. Renal biopsy
1. Description: Insertion of a needle into the kidney to obtain a sample of tissue for examination; usually done percutaneously
2. Preprocedure interventions
   a. Assess vital signs.
   b. Assess baseline coagulation studies; notify the PHCP if abnormal results are noted.
   c. Verify that an informed consent was obtained.
   d. Withhold food and fluids as prescribed.
3. Intervention during the procedure: Position the client prone with a pillow under the abdomen and shoulders.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Postprocedure interventions
   a. Monitor vital signs, especially for hypotension and tachycardia, which could indicate bleeding.
   b. Provide pressure to the biopsy site for 30 minutes or as prescribed.
   c. Monitor the hemoglobin and hematocrit levels for decreases, which could indicate bleeding.
   d. Place the client on strict bed rest in the supine position with a back roll for additional support for 2 to 6 hours after the biopsy.
   e. Check the biopsy site and under the client for bleeding.
   f. Encourage fluid intake of 1500 to 2000 mL as prescribed.
   g. Observe the urine for gross and microscopic bleeding.
   h. Instruct the client to avoid heavy lifting and strenuous activity for 1 to 2 weeks.
   i. Instruct the client to notify the PHCP if either a temperature greater than 100° F (37.8° C) or hematuria occurs after the first 24 hours postprocedure.

III. Acute Kidney Injury

A. Description
1. **Acute kidney injury (AKI)** is the rapid loss of kidney function from renal cell damage.
2. Occurs abruptly and can be reversible
3. AKI leads to cell hypoperfusion, cell death, and decompensation of renal function.
4. The prognosis depends on the cause and the condition of the client.
5. Near-normal or normal kidney function may resume gradually.

B. Causes
1. Prerenal: Outside the kidney; caused by intravascular volume depletion such as with blood loss associated with trauma or surgery, dehydration, decreased cardiac output (as with cardiogenic shock), decreased peripheral vascular resistance, decreased renovascular blood flow, and prerenal infection or obstruction
2. Intrarenal: Within the parenchyma of the kidney; caused by tubular necrosis, prolonged prerenal ischemia, intrarenal infection or obstruction, and nephrotoxicity (Box 55.3)
3. Postrenal: Between the kidney and urethral meatus, such as bladder neck obstruction, bladder cancer, calculi, and postrenal infection

C. Phases of AKI and interventions (Box 55.4)
1. Onset: Begins with precipitating event
2. Oliguric phase
   a. For some clients, **oliguria** does not occur and the urine output is normal; otherwise, the duration of oliguria is 8 to 15 days; the longer the duration, the less chance of recovery.

BOX 55.3 Potentially Nephrotoxic Substances

Medications

Antibiotics: Antiinfectives
- Amphotericin B
- Methicillin
- Polymyxin B
- Rifampin
- Sulfonamides
- Tetracycline hydrochloride
- Vancomycin

Aminoglycoside Antibiotics
- Gentamicin
- Kanamycin
- Neomycin
- Tobramycin

Antineoplastics
- Cisplatin
- Cyclophosphamide
- Methotrexate

Nonsteroidal Antiinflammatory Drugs (NSAIDs)
- Celecoxib
- Flurbiprofen
- Ibuprofen
- Indomethacin
- Ketorolac
- Meclofenamate
- Meloxicam
- Nabumetone
- Naproxen
- Oxaprozin
- Rofecoxib
- Tolmetin

Other Medications
- Acetaminophen
- Captopril
- Cyclosporine
- Fluorinate anesthetics
- D-Penicillamine
- Phenazopyridine hydrochloride
- Quinine

Other Substances
- Carbon tetrachloride
- Ethylene glycol
- Organic solvents

Nonpharmacological Chemical Agents
- Fungicides
- Myoglobin (from breakdown of skeletal muscle)
- Radiographic contrast dye
- Pesticides

Heavy Metals and Ions
- Arsenic
- Bismuth
- Copper sulfate
- Gold salts
- Lead
- Mercuric chloride

Adapted from Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1377.

   b. Sudden decrease in urine output; urine output is less than 400 mL/day.
   c. Signs of excess fluid volume: Hypertension, edema, pleural and pericardial effusions, dysrhythmias, heart failure, and pulmonary edema
   d. Signs of uremia: Anorexia, nausea, vomiting, and pruritus
   e. Signs of metabolic acidosis: Kussmaul's respirations
   f. Signs of neurological changes: Tingling of extremities, drowsiness progressing to disorientation, and then coma
   g. Signs of pericarditis: Friction rub, chest pain with inspiration, and low-grade fever
   h. Laboratory analysis (see Box 55.4)
   i. With early recognition or potential for AKI, client may be treated with fluid challenges (IV boluses of 500 to 1000 mL over 1 hour).

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

j. Restrict fluid intake; if hypertension is present, daily fluid allowances may be 400 to 1000 mL plus the measured urinary output.

k. Administer medications, such as diuretics, as prescribed to increase renal blood flow and diuresis of retained fluid and electrolytes.

3. Diuretic phase

a. Urine output rises slowly, followed by diuresis (4 to 5 L/day).

b. Excessive urine output indicates that damaged nephrons are recovering their ability to excrete wastes.

c. Dehydration, hypovolemia, hypotension, and tachycardia can occur.

d. Level of consciousness improves.

e. Laboratory analysis (see Box 55.4)

f. Administer IV fluids as prescribed, which may contain electrolytes to replace losses.

4. Recovery phase (convalescent)

a. Recovery is a slow process; complete recovery may take 1 to 2 years.

b. Urine volume returns to normal.

c. Memory improves.

d. Strength increases.

e. The older adult is less likely than a younger adult to regain full kidney function.

f. Laboratory analysis (see Box 55.4)

g. AKI can progress to **chronic kidney disease (CKD).**

The signs and symptoms of AKI are primarily caused by the retention of nitrogenous wastes, the retention of fluids, and the inability of the kidneys to regulate electrolytes.

D. Assessment: Assess objective and subjective data noted in the phases of AKI (see Box 55.4).

E. Other interventions (see Clinical Judgment: Analyze Cues Box)

1. Monitor vital signs, especially for signs of hypertension, tachycardia, tachypnea, and an irregular heart rate.

2. Monitor urine and intake and output hourly and urine color and characteristics.

3. Monitor daily weight (same scale, same clothes, same time of day), noting that an increase of 0.5 to 1 lb/day (0.25 to 0.5 kg/day) indicates fluid retention.

4. Monitor for changes in the BUN, serum creatinine, and serum electrolyte levels.

5. Monitor for acidosis (may need to be treated with sodium bicarbonate).

6. Monitor urinalysis for protein level, hematuria, casts, and specific gravity.

7. Monitor for altered level of consciousness caused by uremia.

BOX 55.4 Acute Kidney Injury: Phases and Laboratory Findings

Onset

- Begins with precipitating event

Oliguric Phase

- Elevated blood urea nitrogen (BUN) and serum creatinine levels
- Decreased urine specific gravity (prerenal causes) or normal (intrarenal causes)
- Decreased glomerular filtration rate (GFR) and creatinine clearance
- Hyperkalemia
- Normal or decreased serum sodium level
- Hypervolemia
- Hypocalcemia
- Hyperphosphatemia

Diuretic Phase

- Gradual decline in BUN and serum creatinine levels, but still elevated
- Continued low creatinine clearance with improving GFR
- Hypokalemia
- Hyponatremia
- Hypovolemia

Recovery Phase (Convalescent)

- Increased GFR
- Stabilization or continual decline in BUN and serum creatinine levels toward normal
- Complete recovery (may take 1 to 2 years)

8. Monitor for signs of infection because the client may not exhibit an elevated temperature or an increased WBC count.

9. Monitor the lungs for fine **crackles**, wheezes, and rhonchi, and monitor for edema, which can indicate fluid overload.

10. Administer the prescribed diet, which is usually a low- to moderate-protein (to decrease the workload on the kidneys) and high-carbohydrate diet; ill clients may require nutritional support with supplements, enteral feedings, or parenteral nutrition.

11. Restrict potassium and sodium intake as prescribed based on the electrolyte level.

12. Administer medications as prescribed; be alert to the mechanism for metabolism and excretion of all prescribed medications.

13. Be alert to nephrotoxic medications, which may be prescribed (see Box 55.3).

14. Be alert to the PHCP's adjustment of medication dosages for kidney injury.

15. Prepare the client for **dialysis** if prescribed; continuous renal replacement therapy may be used in AKI to treat fluid volume overload or rapidly developing **azotemia** and metabolic acidosis.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

16. Provide emotional support by allowing opportunities for the client to express concerns and fears and by encouraging family interactions.
17. Promote consistency in caregivers.
18. Also refer to Section IV, E in this chapter (Special problems in kidney disease and interventions).

CLINICAL JUDGMENT: ANALYZE CUES

The nurse is caring for a hospitalized client with a history of heart failure and a diagnosis of urinary tract infection. On assessment, the nurse notes that the client's urine output has decreased to 15 mL/hour and that the blood pressure has increased to 190/110 mm Hg. Auscultation of lung sounds reveal fine crackles and wheezes in the lung bases bilaterally. The client is dyspneic and has jugular vein distention and peripheral edema. The nurse analyzes the cues and interprets the findings as indicating possible acute kidney injury and fluid overload.

IV. Chronic Kidney Disease (CKD)

A. Description
1. CKD is a slow, progressive, irreversible loss in kidney function, with a GFR less than or equal to 60 mL per minute for 3 months or longer.
2. It occurs in stages (with loss of 75% of functioning nephrons, the client becomes symptomatic) and eventually results in uremia or end-stage kidney disease (with loss of 90% to 95% of functioning nephrons) (Table 55.2).
3. Hypervolemia can occur because of the kidneys' inability to excrete sodium and water; hypovolemia can occur because of the kidneys' inability to conserve sodium and water.

CKD affects all major body systems and may require dialysis or kidney transplantation to maintain life.

B. Primary causes
1. May follow AKI
2. Diabetes mellitus and other metabolic disorders
3. Hypertension
4. Chronic urinary obstruction
5. Recurrent infections
6. Renal artery occlusion
7. Autoimmune disorders

C. Assessment
1. Assess body systems for the manifestations of CKD (Box 55.5).
2. Assess psychological changes, which could include emotional lability, withdrawal, depression, anxiety, denial, dependence–independence conflict, changes in body image, and suicidal behavior.

TABLE 55.2 Progression of Chronic Kidney Disease

Stage of CKD	Estimated GFR
At risk; normal kidney function (early kidney disease may or may not be present)	>90 mL/min
Mild CKD	60-89 mL/min
Moderate CKD	30-59 mL/min
Severe CKD	15-29 mL/min
ESRD	<15 mL/min

CKD, Chronic kidney disease; *ESRD*, end-stage renal disease; *GFR*, glomerular filtration rate.

Data from Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care*. (10th ed.). St. Louis: Elsevier. p. 1384.

D. Interventions
1. Same as the interventions for AKI.
2. Administer a prescribed diet, which is usually a moderate-protein (to decrease the workload on the kidneys) and high-carbohydrate, low-potassium, and low-phosphorus diet.
3. Provide oral care to prevent stomatitis and reduce discomfort from mouth sores.
4. Provide skin care to prevent pruritus.
5. Teach the client about fluid and dietary restrictions and about the importance of daily weights.
6. Provide support to promote acceptance of the chronic illness, and prepare the client for long-term dialysis and transplantation, or explain to the client about the choice to decline dialysis or transplantation; with elderly clients, provide information that kidney function is declining and in time may reach end-stage renal disease and require dialysis; encourage healthy lifestyle and discuss choices.

E. Special problems in kidney disease and interventions (Box 55.6)
1. Activity intolerance and insomnia
   a. Fatigue results from anemia and the buildup of wastes from the diseased kidneys.
   b. Provide adequate rest periods.
   c. Teach the client to plan activities to avoid fatigue.
   d. Mild central nervous system (CNS) depressants may be prescribed to promote rest.
2. Anemia
   a. Anemia results from the decreased secretion of erythropoietin by damaged nephrons, resulting in decreased production of red blood cells.
   b. Monitor for decreased hemoglobin and hematocrit levels.
   c. Administer hematopoietics such as epoetin alfa or darbepoetin alfa, as prescribed, to promote maturity of the red blood cells.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 55.5 Key Features of Chronic Kidney Disease

Neurological Manifestations
- Asterixis
- Ataxia (alteration in gait)
- Coma
- Inability to concentrate or decreased attention span
- Lethargy and daytime drowsiness
- Myoclonus
- Paresthesias
- Seizures
- Slurred speech
- Tremors, twitching, or jerky movements

Cardiovascular Manifestations
- Cardiac tamponade
- Cardiomyopathy
- Heart failure
- Hypertension
- Pericardial effusion
- Pericardial friction rub
- Peripheral edema
- Uremic pericarditis

Respiratory Manifestations
- Crackles
- Deep sighing, yawning
- Depressed cough reflex
- Kussmaul's respirations
- Shortness of breath
- Tachypnea
- Pleural effusion
- Pulmonary edema
- Uremic halitosis
- Uremic pneumonia

Hematological Manifestations
- Abnormal bleeding and bruising
- Anemia

Gastrointestinal Manifestations
- Anorexia, nausea, vomiting
- Changes in taste acuity and sensation
- Constipation
- Diarrhea
- Metallic taste in the mouth
- Stomatitis
- Uremic colitis (diarrhea)
- Uremic fetor
- Uremic gastritis (possible gastrointestinal bleeding)

Urinary Manifestations
- Diluted, straw-colored appearance
- Hematuria
- Oliguria, anuria (later)
- Polyuria, nocturia (early)
- Proteinuria

Integumentary Manifestations
- Decreased skin turgor
- Dry skin
- Ecchymosis
- Pruritus
- Purpura
- Soft tissue calcifications
- Uremic frost (late, premorbid)
- Yellow-gray pallor

Musculoskeletal Manifestations
- Bone pain
- Muscle weakness and cramping
- Pathological fractures
- Renal osteodystrophy

Reproductive Manifestations
- Decreased fertility
- Decreased libido
- Impotence
- Infrequent or absent menses

From Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1388.

BOX 55.6 Special Problems in Kidney Disease
- Activity intolerance and insomnia
- Anemia
- Gastrointestinal bleeding
- Hyperkalemia
- Hypermagnesemia
- Hyperphosphatemia
- Hypertension
- Hypervolemia
- Hypocalcemia
- Hypovolemia
- Infection
- Metabolic acidosis
- Muscle cramps
- Neurological changes
- Ocular irritation
- Potential for injury
- Pruritus
- Psychosocial problems

d. Administer folic acid as prescribed.
e. Administer iron orally as prescribed, but not at the same time as phosphate binders.
f. Administer stool softeners as prescribed because of the constipating effects of iron.
g. Note that oral iron is not well absorbed by the GI tract in CKD and causes nausea and vomiting; parenteral iron may be used if iron deficiencies persist despite folic acid or oral iron administration.
h. Administer blood transfusions, which are prescribed only when necessary (acute blood loss, symptomatic anemia) because they decrease the stimulus to produce red blood cells.
i. Blood transfusions also cause the development of antibodies against human tissues, which can make matching for organ transplantation difficult.

3. Gastrointestinal bleeding
   a. Urea is broken down by the intestinal bacteria to ammonia; ammonia irritates the GI mucosa, causing ulceration and bleeding.
   b. Monitor for decreasing hemoglobin and hematocrit levels.
   c. Monitor stools for occult blood.
   d. Avoid the administration of acetylsalicylic acid, because it is excreted by the kidneys; if administered, aspirin toxicity can occur and prolong the bleeding time.

! Place the client with kidney disease on continuous telemetry. The client can develop hyperkalemia, resulting in the risk for dysrhythmias.

4. Hyperkalemia
   a. Monitor vital signs for hypertension or hypotension and the apical heart rate; an irregular heart rate could indicate dysrhythmias.
   b. Monitor the serum potassium level; an elevated serum potassium level can cause decreased cardiac output, heart blocks, fibrillation, or asystole (Fig. 55.1).
   c. Provide a low-potassium diet (see Chapter 11 for a list of foods that are high in potassium).
   d. Administer electrolyte-binding and electrolyte-excreting medications such as oral or rectal sodium polystyrene sulfonate as prescribed to lower the serum potassium level.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

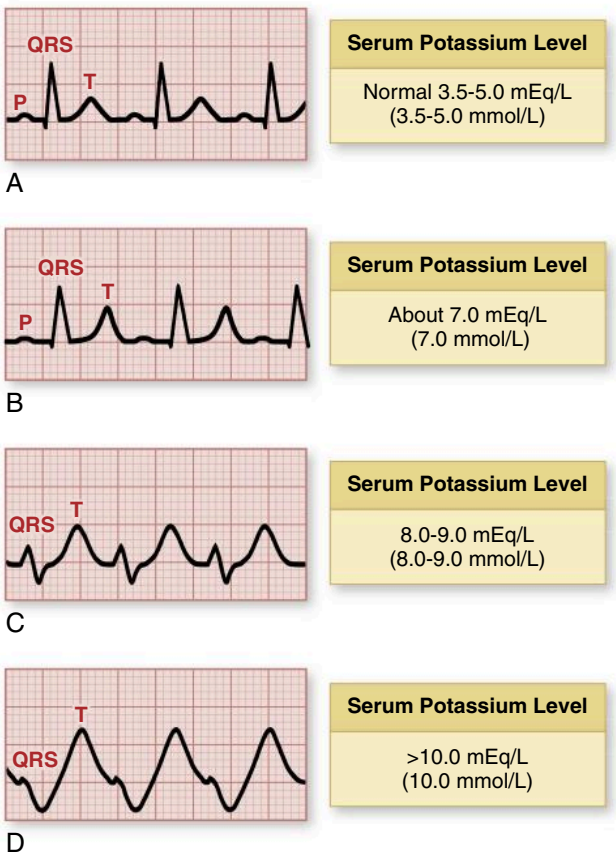

FIG. 55.1 Cardiac rhythm changes with hyperkalemia.

e. Administer prescribed medications: 50% dextrose and regular insulin IV may be prescribed to shift potassium into the cells; calcium gluconate IV may be prescribed to reduce myocardial irritability from hyperkalemia; and sodium bicarbonate IV may be prescribed to correct acidosis.

f. Administer prescribed loop diuretics to excrete potassium.

g. Avoid potassium-sparing medications such as spironolactone and triamterene because these medications will increase the potassium level.

h. Prepare the client for peritoneal dialysis (PD) or hemodialysis as prescribed.

5. Hypermagnesemia

a. Results from decreased renal excretion of magnesium.

b. Monitor for cardiac manifestations such as bradycardia, peripheral vasodilation, and hypotension.

c. Monitor CNS changes, such as drowsiness or lethargy.

d. Monitor neuromuscular manifestations, such as reduced or absent deep tendon reflexes or weak or absent voluntary skeletal muscle contractions.

e. Administer loop diuretics as prescribed to excrete magnesium.

f. Administer calcium as prescribed for resulting cardiac problems.

g. Avoid medications that contain magnesium, such as antacids; some laxatives and enemas may also contain magnesium.

h. During severe elevations, avoid foods that increase magnesium levels (see Chapter 11 for a list of foods that are high in magnesium).

6. Hyperphosphatemia

a. As the phosphorus level rises, the calcium level drops; this leads to the stimulation of parathyroid hormone, causing bone demineralization.

b. Treatment is aimed at lowering the serum phosphorus level.

c. Administer phosphate binders as prescribed with meals to lower serum phosphate levels.

d. Administer stool softeners and laxatives as prescribed, because phosphate binders are constipating.

e. Teach the client about the need to limit the intake of foods high in phosphorus (see Chapter 11 for a list of foods that are high in phosphorus).

7. Hypertension

a. Caused by failure of the kidneys to maintain BP homeostasis.

b. Monitor vital signs for elevated BP.

c. Maintain fluid and sodium restrictions as prescribed.

d. Administer diuretics and antihypertensives as prescribed.

8. Hypervolemia

a. Monitor vital signs for an elevated BP.

b. Monitor intake and output and daily weight for indications of fluid retention.

c. Monitor for periorbital, sacral, and peripheral edema.

d. Monitor the serum electrolyte levels.

e. Monitor for hypertension, and notify the PHCP if there are sustained elevations.

f. Monitor for signs of heart failure and pulmonary edema, such as restlessness, heightened anxiety, tachycardia, dyspnea, basilar lung crackles, and blood-tinged sputum; notify the PHCP immediately if signs occur.

g. Maintain fluid restriction.

h. Avoid the administration of large amounts of IV fluids.

i. Administer diuretics as prescribed.

j. Teach the client to maintain a low-sodium diet.

k. Teach the client to avoid over-the-counter medications without checking with the PHCP.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

9. Hypocalcemia
   a. Results from a high phosphorus level and the inability of the diseased kidney to activate vitamin D
   b. The absence of vitamin D causes poor calcium absorption from the intestinal tract.
   c. Monitor the serum calcium level.
   d. Administer calcium supplements as prescribed.
   e. Administer activated vitamin D as prescribed.
   f. See Chapter 11 for a list of foods that are high in calcium.
10. Hypovolemia
   a. Monitor the vital signs for hypotension and tachycardia.
   b. Monitor for decreasing intake and output and a reduction in the daily weight.
   c. Monitor for dehydration.
   d. Monitor electrolyte levels.
   e. Provide replacement therapy based on the serum electrolyte level values.
11. Infection
   a. The client is at risk for infection caused by a suppressed immune system, dialysis access site, and possible malnutrition.
   b. Monitor for signs of infection.
   c. Avoid urinary catheters when possible; if used, provide catheter care per protocol.
   d. Provide strict asepsis during urinary catheter insertion and other invasive procedures.
   e. Instruct the client to avoid fatigue and avoid persons with infections.
   f. Administer antibiotics as prescribed, monitoring for nephrotoxic effects.
12. Metabolic acidosis
   a. The kidneys are unable to excrete hydrogen ions or manufacture bicarbonate, resulting in acidosis.
   b. Administer alkalizers such as sodium bicarbonate as prescribed.
   c. Note that clients with CKD adjust to low bicarbonate levels and as a result do not become acutely ill.
13. Muscle cramps
   a. Occur from electrolyte imbalances and the effects of uremia on peripheral nerves
   b. Monitor serum electrolyte levels.
   c. Administer electrolyte replacements and medications to control muscle cramps as prescribed.
   d. Administer heat and massage as prescribed.
14. Neurological changes
   a. The buildup of active particles and fluids causes changes in the brain cells and leads to confusion and impairment in decision-making ability.
   b. Peripheral neuropathy results from the effects of uremia on peripheral nerves.
   c. Monitor the level of consciousness and for confusion.
   d. Monitor for restless legs syndrome, which is also common during dialysis treatments.
   e. Teach the client to examine areas of decreased sensation for signs of injury.
15. Ocular irritation
   a. Calcium deposits in the conjunctivae cause burning and watering of the eyes.
   b. Administer medications to control the calcium and phosphate levels as prescribed.
   c. Administer lubricating eye drops.
   d. Protect the client from injury.
16. Potential for injury
   a. The client is at risk for fractures caused by alterations in the absorption of calcium, excretion of phosphate, and vitamin D metabolism.
   b. Provide for a safe environment.
   c. Avoid injury; tissue breakdown causes increased serum potassium levels.
17. Pruritus
   a. To rid the body of excess wastes, urate crystals are excreted through the skin, causing pruritus.
   b. The deposit of urate crystals (uremic frost) occurs in advanced stages of kidney disease.
   c. Monitor for skin breakdown, rash, and uremic frost.
   d. Provide meticulous skin care and oral hygiene.
   e. Avoid the use of soaps.
   f. Administer antihistamines and antipruritics as prescribed to relieve itching.
   g. Teach the client to keep the nails trimmed to prevent local infection from scratching.
18. Psychosocial problems
   a. Listen to the client's concerns to determine how the client is handling the situation.
   b. Allow the client time to mourn the loss of kidney function.
   c. With client permission, include the family members in discussions of the client's concerns.
   d. Provide education about treatment options and support the client's decision; elderly clients with CKD may progress slowly toward end-stage kidney disease or require dialysis, and clients may decide on no treatment and opt for end-of-life care.
   e. Offer information about support groups.

V. Uremic Syndrome

A. Description: Systemic clinical and laboratory manifestations of severe and/or end-stage kidney disease due to accumulation of nitrogenous waste products in the blood caused by the kidneys' inability to filter out these waste products

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Assessment
1. Oliguria
2. Presence of protein, red blood cells, and casts in the urine
3. Elevated levels of urea, uric acid, potassium, and magnesium in the urine
4. Hypotension or hypertension
5. Alterations in the level of consciousness
6. Electrolyte imbalances
7. Stomatitis
8. Nausea or vomiting
9. Diarrhea or constipation

C. Interventions
1. Monitor vital signs for hypertension, tachycardia, and an irregular heart rate.
2. Monitor serum electrolyte levels.
3. Monitor intake and output and for oliguria.
4. Provide a limited but high-quality protein diet as prescribed.
5. Provide a limited sodium, nitrogen, potassium, and phosphate diet as prescribed.
6. Assist the client to cope with body image disturbances caused by uremic syndrome.

VI. Hemodialysis

A. Description
1. Hemodialysis is an intermittent renal replacement therapy involving the process of cleansing the client's blood.
2. It involves the diffusion of dissolved particles from one fluid compartment into another across a semipermeable membrane; the client's blood flows through one fluid compartment of a dialysis filter, and the dialysate is in another fluid compartment.

B. Functions of hemodialysis
1. Cleanses the blood of accumulated waste products
2. Removes the byproducts of protein metabolism such as urea, creatinine, and uric acid from the blood
3. Removes excess body fluids
4. Maintains or restores the buffer system of the body
5. Corrects electrolyte levels in the body

C. Principles of hemodialysis
1. The semipermeable membrane is made of a thin, porous cellophane.
2. The pore size of the membrane allows small particles to pass through, such as urea, creatinine, uric acid, and water molecules.
3. Proteins, bacteria, and some blood cells are too large to pass through the membrane.
4. The client's blood flows into the dialyzer; the movement of substances occurs from the blood to the dialysate by the principles of osmosis, diffusion, and ultrafiltration.
5. Osmosis is the movement of fluids across a semipermeable membrane from an area of lower concentration of particles to an area of higher concentration of particles.
6. Diffusion is the movement of particles from an area of higher concentration to one of lower concentration.
7. Ultrafiltration is the movement of fluid across a semipermeable membrane as a result of an artificially created pressure gradient.

D. Dialysate bath
1. A dialysate bath is composed of water and major electrolytes.
2. The dialysate need not be sterile because bacteria and viruses are too large to pass through the pores of the semipermeable membrane; however, the dialysate must meet specific standards, and water is treated to ensure a safe water supply.

E. Interventions
1. Monitor vital signs before, during, and after dialysis; the client's temperature may elevate because of slight warming of the blood from the dialysis machine (notify the PHCP about excessive temperature elevations because this could indicate sepsis, requiring blood cultures to be collected).
2. Monitor laboratory values, specifically the BUN, creatinine, and complete blood cell counts before, during, and after dialysis.
3. Assess the client for fluid overload before dialysis and fluid volume deficit following dialysis.
4. Weigh the client before and after dialysis to determine fluid loss. Note that the client will not urinate or will urinate small amounts (may be less than 30 mL/hr).
5. Assess the patency of the blood access device before, during, and after dialysis.
6. Monitor for bleeding; heparin is added to the dialysis blood tubing to prevent clots from forming in the dialyzer or the blood tubing.
7. Monitor for hypovolemia during dialysis, which can occur from blood loss or excess fluid and electrolyte removal.
8. Provide adequate nutrition; the client may eat before or during dialysis.
9. Identify the client's reactions to the treatment and support coping mechanisms; encourage independence and involvement in care.
10. Assess the client's understanding of fluid and dietary restrictions ordered by the nephrologist.

Withhold antihypertensives and other medications that can affect the BP or result in hypotension until after hemodialysis treatment. Also withhold medications that could be removed by dialysis, such as water-soluble vitamins, certain antibiotics, and digoxin.

Telegram & Insta: NCLEX_RN_Edu

VII. Access for Hemodialysis

A. Subclavian and femoral catheters

1. Description

a. A subclavian (subclavian vein) or femoral (femoral vein) catheter may be inserted for short-term or temporary use in AKI.

b. The catheter is used until a fistula or graft matures or develops, which is typically 6 weeks, or may be required when the client's fistula or graft access has failed because of infection or clotting.

2. Interventions

a. Assess insertion site for hematoma, bleeding, catheter dislodgment, and infection.

b. These catheters are only to be used for dialysis treatments and accessed by dialysis personnel.

c. Maintain an occlusive dressing over the catheter insertion site.

3. Subclavian vein catheter

a. The catheter is usually filled with heparin and capped to maintain patency between dialysis treatments. Heparin is aspirated from the line before dialysis.

b. The catheter is not to be uncapped except for dialysis treatments.

c. The catheter may be left in place for up to 6 weeks if no complications occur.

4. Femoral vein catheter

a. Assess the extremity for circulation, temperature, and pulses.

b. Prevent pulling or disconnecting of the catheter when giving care.

c. Because the groin is not a clean site, meticulous perineal care is required.

d. Use an IV infusion pump or controller with microdrip tubing if a heparin infusion through the catheter to maintain patency is prescribed.

! The client with a femoral vein catheter that is in use should not sit up more than 45 degrees or lean forward, because the catheter may kink and occlude.

B. External arteriovenous shunt (Fig. 55.2)

1. Description

a. Two Silastic cannulas are surgically inserted into an artery and vein in the forearm or leg to form an external blood path.

b. The cannulas are connected to form a U shape; blood flows from the client's artery through the shunt into the vein.

c. A tube leading to the membrane compartment of the dialyzer is connected to the arterial cannula.

d. Blood fills the membrane compartment, passes through the dialyzer, and is returned to the client through a tube connected to the venous cannula.

e. When dialysis is complete, the cannulas are clamped and reattached, reforming the U shape.

2. Advantages

a. The external arteriovenous shunt can be used immediately following its creation.

b. No venipuncture is necessary for dialysis.

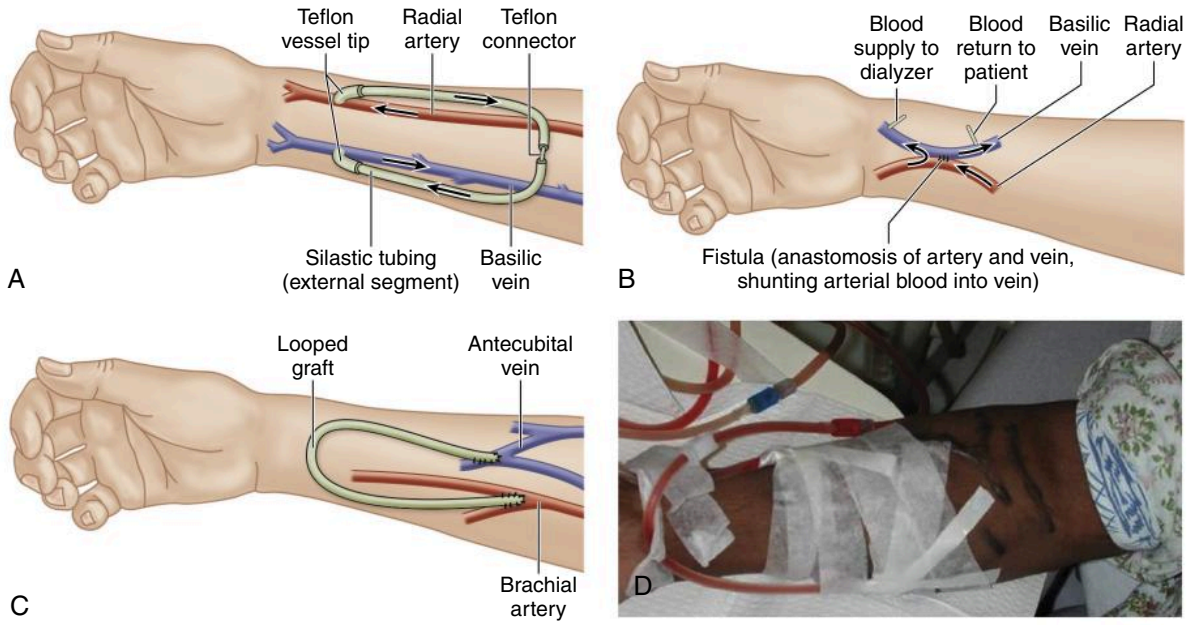

FIG. 55.2 Vascular access for hemodialysis. **A,** External shunt. **B,** Internal arteriovenous fistula. **C,** Internal arteriovenous graft. **D,** A hemodialysis graft while connected to a hemodialysis machine. (**D,** From Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. [2020]. *Medical-surgical nursing: Assessment and management of clinical problems.* [11th ed.]. St. Louis: Elsevier. p. 1077.)

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Disadvantages
   a. Disconnection or dislodgment of the external shunt
   b. Risk of hemorrhage, infection, or clotting
   c. Potential for skin erosion around the catheter site
4. Interventions
   a. Avoid getting the shunt wet.
   b. Wrap a dressing completely around the shunt, and keep it dry and intact.
   c. Keep cannula clamps at the client's bedside or attached to the arteriovenous dressing for use in case of accidental disconnection.
   d. Teach the client that the shunt extremity may not be used for monitoring BP, drawing blood, placing IV lines, or administering injections.
   e. Fold back the dressing to expose the shunt tubing and assess for signs of hemorrhage, infection, or clotting.
   f. Monitor skin integrity around the insertion site.
   g. Auscultate for a bruit and palpate for a thrill, although a bruit may not be heard with the shunt.
   h. Notify the PHCP immediately if signs of clotting, hemorrhage, or infection occur.
5. Signs of clotting
   a. Fibrin: White flecks in the tubing
   b. Separation of serum and cells
   c. Absence of a previously heard bruit; thrill absent on palpation
   d. Coolness of the tubing or extremity
   e. Tingling sensation at site or in extremity

C. Internal **arteriovenous fistula** (see Fig. 55.2)
1. Description
   a. A permanent access of choice for the client with CKD requiring dialysis.
   b. The fistula is created surgically by anastomosis of a large artery and large vein in the arm.
   c. The flow of arterial blood into the venous system causes the vein to become engorged (matured or developed).
   d. Maturity takes about 4 to 6 weeks, depending on the client's ability to do hand-flexing exercises such as ball squeezing, which help the fistula mature.
   e. The fistula is required to be mature before it can be used, because the engorged vein is punctured with a large-bore needle for the dialysis procedure.
   f. Subclavian or femoral catheters, PD, or an external arteriovenous shunt can be used for dialysis while the fistula is maturing or developing.
   g. Avoid taking BP or performing venipuncture for intravenous access or lab draws to protect the integrity of the fistula.
   h. Fistulas are dressed with pressure dressings after hemodialysis to prevent bleeding. Ensure the removal of the pressure dressing within the prescribed time frame or according to agency policy.
2. Advantages
   a. Because the fistula is internal, the risk of clotting and bleeding is low.
   b. The fistula can be used indefinitely.
   c. The fistula has a decreased incidence of infection, because it is internal and is not exposed.
   d. Once healing has occurred, no external dressing is required.
   e. The fistula allows freedom of movement.
3. Disadvantages
   a. The fistula cannot be used immediately after insertion, so planning ahead for an alternative access for dialysis is important.
   b. Needle insertions through the skin and tissues to the fistula are required for dialysis.
   c. Infiltration of the needles during dialysis can occur and cause hematomas.
   d. An aneurysm can form in the fistula without regular site rotation.
   e. Heart failure can occur from the increased blood flow in the venous system.

! Arterial steal syndrome can develop in a client with an internal arteriovenous fistula. In this complication, too much blood is diverted to the vein, and arterial perfusion to the hand is compromised.

D. Internal arteriovenous graft (see Fig. 55.2)
1. Description
   a. The internal graft may be used for chronic dialysis clients who do not have adequate blood vessels for the creation of a fistula.
   b. An artificial graft made of Gore-Tex or a bovine (cow) carotid artery is used to create an artificial vein for blood flow.
   c. The procedure involves the anastomosis of an artery to a vein, using an artificial graft.
   d. The graft can be used 2 weeks after insertion.
   e. Complications of the graft include clotting, aneurysms, and infection.
2. Advantages and disadvantages: Same as for internal arteriovenous fistula

E. Interventions for an arteriovenous fistula and arteriovenous graft
1. Teach the client that the extremity may not be used for monitoring BP, drawing blood, placing IV lines, or administering injections, and that the client should inform all health care personnel of its presence.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Teach the client with an arteriovenous fistula to perform hand-flexing exercises such as ball squeezing (if prescribed) to promote graft maturity.
3. Note the temperature and capillary refill of the extremity.
4. Palpate pulses below the fistula or graft, and monitor for hand swelling as an indication of ischemia.
5. Monitor for clotting.
   a. Complaints of tingling or discomfort in the extremity
   b. Inability to palpate a thrill or auscultate a bruit over the fistula or graft
6. Monitor for **arterial steal syndrome.**
7. Monitor for infection.
8. Monitor lung and heart sounds for signs of heart failure.
9. Notify the PHCP immediately if signs of clotting, infection, or arterial steal syndrome occur.

⚠ To ensure patency, palpate for a thrill or auscultate for a bruit over the fistula or graft. Notify the PHCP if a thrill or bruit is absent.

VIII. Complications of Hemodialysis (Box 55.7)

A. If signs of complications occur, the dialysis is slowed or stopped, depending on the complication, and the PHCP is notified immediately.

B. The nurse stays with the client and monitors the client, including vital signs, while another nurse obtains initial prescriptions from the PHCP.

C. See Clinical Judgment: Take Action Box.

CLINICAL JUDGMENT: TAKE ACTION

The nurse is monitoring a client during a hemodialysis treatment when the client complains of chest pain and difficulty breathing. The nurse notes that the client's pulse rate is 110 beats per minute and the blood pressure is 98/60 mm Hg. Cyanosis is noted around the lips and the pulse oximetry reading is 88%. The nurse suspects an air embolism and takes the following actions:

- Stops the hemodialysis, and does not reinfuse blood
- Turns the client on the left side, with the head down (Trendelenburg's position).
- Stays with the client and asks another person to notify the PHCP and the Rapid Response Team
- Administers oxygen
- Assesses vital signs and pulse oximetry
- Documents the event, actions taken, and the client's response

BOX 55.7 Complications of Hemodialysis

- Air embolus
- Disequilibrium syndrome
- Electrolyte alterations
- Encephalopathy
- Hemorrhage
- Hepatitis
- Hypotension
- Sepsis
- Shock

IX. Peritoneal Dialysis

A. Description

1. The peritoneum acts as the dialyzing membrane (semipermeable membrane) to achieve dialysis, and the membrane is accessed by insertion of a PD catheter through the abdomen.
2. PD works on the principles of osmosis, diffusion, and ultrafiltration; PD occurs via the transfer of fluid and solute from the bloodstream through the peritoneum into the dialysate solution.
3. The peritoneal membrane is large and porous, allowing solutes and fluid to move via osmosis from an area of higher concentration in the body to an area of lower concentration in the dialyzing fluid.
4. The peritoneal cavity is rich in capillaries; therefore, it provides a ready access to the blood supply.

B. Contraindications to PD

1. Peritonitis
2. Recent abdominal surgery
3. Abdominal adhesions
4. Other GI problems such as diverticulosis

C. Access for PD (Fig. 55.3)

1. A siliconized rubber catheter such as a Tenckhoff catheter is surgically inserted into the client's peritoneal cavity to allow infusion of dialysis fluid; the catheter site is covered by a sterile dressing that is changed daily and when soiled or wet.
2. The preferred insertion site is 3 to 5 cm below the umbilicus; this area is relatively avascular and has less fascial resistance.
3. The catheter is tunneled under the skin, through the fat and muscle tissue to the peritoneum; it is stabilized with inflatable Dacron cuffs in the muscle and under the skin.
4. Over a period of 1 to 2 weeks following insertion, fibroblasts and blood vessels grow around the cuffs, fixing the catheter in place and providing an extra barrier against dialysate leakage and bacterial invasion.
5. If the client is scheduled for transplant surgery, the PD catheter may be either removed or left in place if the need for dialysis is suspected post-transplantation.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

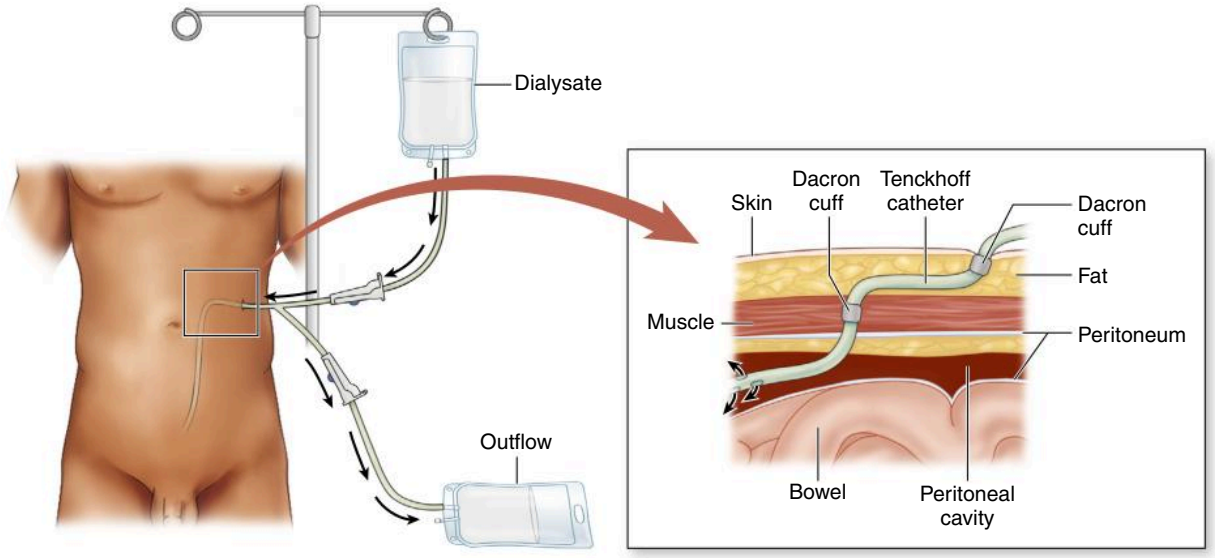

FIG. 55.3 Manual peritoneal dialysis via an implanted abdominal catheter (Tenckhoff catheter).

D. Dialysate solution
1. The solution is sterile.
2. All dialysis solutions are prescribed by the PHCP; the solution contains electrolytes and minerals and has a specific osmolarity, specific glucose concentration, and other medication additives as prescribed.
3. The higher the glucose concentration, the greater the hypertonicity and the amount of fluid removed during a PD exchange.
4. Increasing the glucose concentration increases the concentration of active particles that cause osmosis, increases the rate of ultrafiltration, and increases the amount of fluid removed.
5. If hyperkalemia is not a problem, potassium may be added to each bag of dialysate solution.
6. Heparin is added to the dialysate solution to prevent clotting of the catheter.
7. Prophylactic antibiotics may be added to the dialysate solution to prevent peritonitis.
8. Insulin may be added to the dialysate solution for the client with diabetes mellitus.

E. PD infusion
1. Description
   - **a.** One infusion (fill), dwell, and drain is considered one exchange.
   - **b.** Fill: 1 to 2 L of dialysate as prescribed is infused by gravity into the peritoneal space, which usually takes 10 to 20 minutes.
   - **c.** Dwell time: The amount of time that the dialysate solution remains in the peritoneal cavity is prescribed by the PHCP and can last 20 to 30 minutes to 8 or more hours, depending on the type of dialysis used.
   - **d.** Drain (outflow): Fluid drains out of body by gravity into the drainage bag.
2. Interventions before treatment
   - **a.** Monitor vital signs.
   - **b.** Monitor daily weight on the same scale.
   - **c.** Have the client void, if possible.
   - **d.** Assess electrolyte and glucose levels.
   - **e.** Assess the peritoneal catheter dressing and site; note any evidence of irritation or infection.
3. Interventions during treatment
   - **a.** Monitor vital signs.
   - **b.** Monitor for respiratory distress, pain, or discomfort.
   - **c.** Monitor for signs of pulmonary edema.
   - **d.** Monitor for hypotension and hypertension.
   - **e.** Monitor for malaise, nausea, and vomiting.
   - **f.** Assess the catheter site dressing for wetness or bleeding.
   - **g.** Monitor dwell time as prescribed by the PHCP.
   - **h.** Do not allow dwell time to extend beyond the PHCP's prescription, because this increases the risk for hyperglycemia.
   - **i.** Initiate outflow; turn the client from side to side if the outflow is slow to start.
   - **j.** Monitor outflow, which should be a continuous stream after the clamp is opened.
   - **k.** Monitor outflow for color and clarity.
   - **l.** Monitor intake and output accurately; if outflow is less than inflow, the difference is equal to the amount absorbed or retained by the client during dialysis and should be counted as intake.
   - **m.** An outflow greater than inflow as well as the appearance of frank blood or cloudiness in the outflow should be reported to the PHCP.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

F. Types of PD

1. Continuous ambulatory peritoneal dialysis (CAPD)
   - **a.** Closely resembles renal function because it is a continuous process
   - **b.** Does not require a machine for the procedure
   - **c.** Promotes client independence
   - **d.** The client performs self-dialysis 24 hours a day, 7 days a week.
   - **e.** Four dialysis cycles are usually administered in a 24-hour period, including an overnight 8-hour dwell time.
   - **f.** Dialysate, 1.5 to 2 L, is instilled into the abdomen 4 times daily and allowed to dwell as prescribed (bags are weighed to determine output); the catheter is clamped and the bag is rolled up during dwell time.
   - **g.** After dwell, the bag is placed lower than the insertion site and the clamp is opened so that fluid drains out by gravity flow.
   - **h.** After fluid is drained, the bag is changed, new dialysate is instilled into the abdomen, and the process continues.
   - **i.** Between exchanges, the catheter is clamped.
2. Automated peritoneal dialysis (Box 55.8)
   - **a.** Automated dialysis requires a peritoneal cycling machine.
   - **b.** Automated dialysis can be done as intermittent peritoneal dialysis, continuous cycling peritoneal dialysis, or nightly peritoneal dialysis.
   - **c.** The exchanges are automated instead of manual.

BOX 55.8 Types of Automated Peritoneal Dialysis

Continuous Cycling Peritoneal Dialysis

- Dialysis requires a peritoneal cycling machine.
- Dialysis usually consists of three cycles done at night and one cycle with an 8-hour dwell done in the morning.
- The sterile catheter system is opened only for the on-and-off procedures, which reduces the risk of infection.
- The client does not need to do exchanges during the day.

Intermittent Peritoneal Dialysis

- Dialysis requires a peritoneal cycling machine.
- Dialysis is not a continuous procedure.
- Dialysis is performed for 10 to 14 hours, 3 or 4 times a week.

Nightly Peritoneal Dialysis

- Dialysis requires a cycling machine.
- Dialysis is performed for 8 to 12 hours each night, with no daytime exchanges or dwells.

X. Complications of Peritoneal Dialysis

Infection is a concern with PD; sites of infection are either the catheter insertion site or the peritoneum, causing peritonitis.

A. Peritonitis

1. Monitor for signs and symptoms of peritonitis: Fever, cloudy outflow, rebound abdominal tenderness, abdominal pain, general malaise, nausea, and vomiting.
2. Cloudy or opaque outflow is an early sign of peritonitis.
3. If peritonitis is suspected, obtain a sample for culture and sensitivity of the outflow to determine the infective organism.
4. Antibiotics may be added to the dialysate.
5. Avoid infections by maintaining meticulous sterile technique when connecting and disconnecting PD solution bags and when caring for the catheter insertion site.
6. Prevent the catheter insertion site dressing from becoming wet during care of the client or the dialysis procedure; change the dressing if wet or soiled.
7. Follow institutional procedure for connecting and disconnecting PD solution bags, which may include scrubbing the connection sites with an antiseptic solution.

B. Abdominal pain

1. Peritoneal irritation during inflow commonly causes abdominal cramping and discomfort during the first few exchanges; the pain usually disappears after 1 to 2 weeks of dialysis treatments.
2. Warm the dialysate before administration, using a special dialysate warmer pad, because the cold temperature of the dialysate can cause discomfort.

C. Abnormal outflow characteristics indicative of complications

1. Bloody outflow after the first few exchanges indicates vascular complications (the outflow should be clear after the initial exchanges).
2. Brown outflow indicates bowel perforation.
3. Urine-colored outflow indicates bladder perforation.
4. Cloudy outflow indicates peritonitis.

D. Insufficient outflow

1. The main cause of insufficient outflow is a full colon; encourage a high-fiber diet, because constipation can cause inflow and outflow problems. Administer stool softeners as prescribed.
2. Insufficient outflow may also be caused by catheter migration out of the peritoneal area; if this occurs, an x-ray will be prescribed to evaluate catheter position.
3. Maintain the drainage bag below the client's abdomen.
4. Check for kinks in the tubing.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

5. Change the client's outflow position by turning the client to a side-lying position or ambulating the client.
6. Check for fibrin clots in the tubing and milk the tubing to dislodge the clot as prescribed.

E. Leakage around the catheter site
1. Clear fluid that leaks from the catheter exit site will be noted.
2. It takes 1 to 2 weeks following insertion of the catheter before fibroblasts and blood vessels grow into the catheter cuffs, which fix it in place and provide an extra barrier against dialysate leakage and bacterial invasion.
3. Smaller amounts of dialysate need to be used; it may take up to 2 weeks for the client to tolerate a full 2-L exchange without leaking around the catheter site.

XI. Kidney Transplantation (Fig. 55.4)

A. Description
1. A human kidney from a compatible donor is implanted into a recipient.
2. Kidney transplantation is performed for irreversible kidney failure; specific criteria are established for eligibility for a transplant.
3. The recipient must take immunosuppressive medications for life.

B. Donors
1. Donors may be living donors (related or unrelated to the client), non–heart-beating donors (NHBDs), or cadaver donors.
2. The most desirable source of kidneys for transplantation is living related donors who closely match the client.
3. Non–heart-beating donors are those who have been declared dead by cardiopulmonary criteria and have organs harvested immediately after death; these persons have consented previously to organ donation.
4. Cadaver donors are those who have suffered irreversible brain injury; these persons are maintained with mechanical ventilation and must have adequate perfusion to the kidneys.
5. Physical criteria for donors include absence of systemic disease and infection, no history of cancer, no kidney disease or hypertension, and adequate kidney function.
6. Donors are screened for ABO blood group, tissue-specific antigen, human leukocyte antigen suitability, and mixed lymphocyte culture index (histocompatibility); donors are also screened for the presence of any communicable diseases and undergo a complete medical evaluation as well as a nephrology consultation.
7. The donor must be in excellent health, with two properly functioning kidneys.
8. The emotional well-being of the donor is determined.
9. Complete understanding of the donation process and outcome by the donor is necessary; usually kidney removal from the donor is done using a laparoscopic procedure.

C. Preoperative interventions
1. Verify histocompatibility tests of donor, which will be done by organ bank personnel.
2. Administer immunosuppressive medications to the recipient as prescribed.
3. Maintain strict aseptic technique.
4. Verify that hemodialysis of the recipient was completed 24 hours before transplantation.
5. Ensure that the recipient is free of any infections.
6. Assess renal function studies.

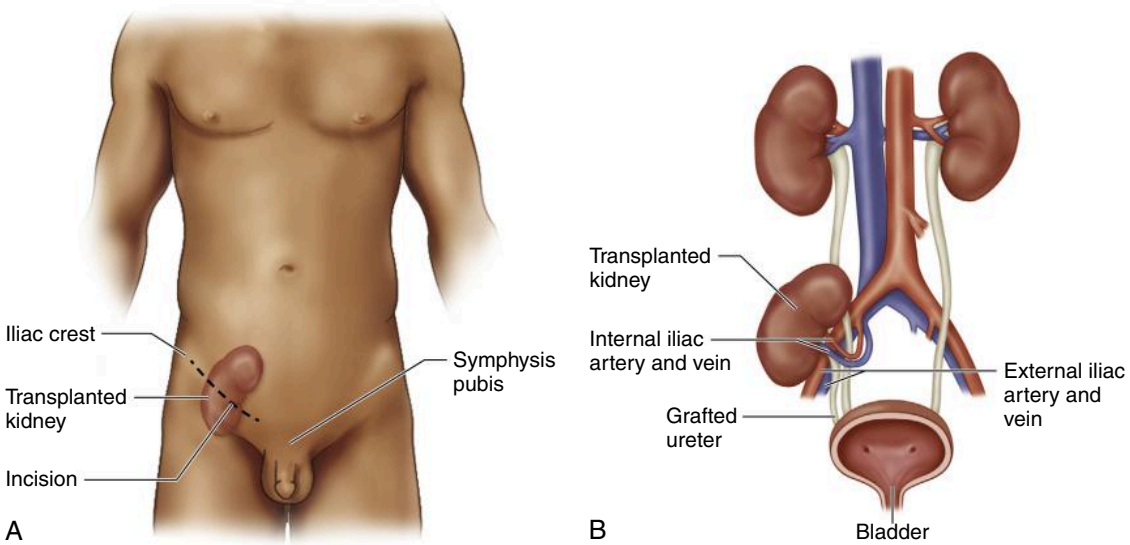

FIG. 55.4 **A,** Surgical incision for renal transplantation. **B,** Surgical placement of transplanted kidney.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

7. Encourage discussion of feelings of the live donor and the recipient.
8. Provide psychological support to the live donor, NHBD family, or cadaver donor family and to the recipient.

D. Postoperative interventions for the recipient

1. The transplanted kidney is placed in the anterior iliac fossa; usually the recipient's diseased kidneys are left in place, except for those with polycystic kidney disease, in which the kidneys are often very enlarged and painful.
2. Urine output usually begins immediately if the donor was a living donor; it may be delayed for a few days or more with other donor types.
3. Hemodialysis may be performed until adequate kidney function is established.
4. Monitor vital signs and for signs of complications such as rejection, thrombosis, renal artery stenosis, or wound problems.
5. Monitor urine output hourly; immediately report an abrupt decrease in output.
6. Monitor IV fluids closely; for the first 12 to 24 hours, IV fluid replacement is based on hourly urine output.
7. Administer prescribed diuretics and osmotic agents.
8. Monitor daily weight to evaluate fluid status.
9. Monitor daily laboratory results to evaluate renal function, including hematocrit, BUN, and serum creatinine levels, and monitor urine for blood and specific gravity.
10. Position the client in a semi-Fowler's position to promote gas exchange, turning from the back to the nonoperative side.
11. Monitor urinary catheter patency; the urinary catheter usually remains in the bladder for 3 to 5 days to allow for anastomosis healing; it is removed as soon as possible to prevent infection.
12. Note that urine is pink and may be bloody initially but gradually returns to normal within several days to weeks.
13. Notify the surgeon if gross hematuria and clots are noted in the urine.
14. Monitor the three-way bladder irrigation, if present, for clots; irrigate only if a surgeon's prescription is present.
15. Maintain aseptic technique and monitor for infection.
16. Maintain strict aseptic technique with wound care.
17. Monitor for bowel sounds and for the passage of flatus; initiate a specific diet and oral fluids as prescribed when flatus and bowel sounds return (usually, fluids, sodium, and potassium are restricted if the client is oliguric).
18. Maintain good oral hygiene, monitoring for stomatitis and bacterial and fungal infections.
19. Encourage coughing and deep-breathing exercises.
20. Administer immunosuppressive medications as prescribed.
21. Assess for signs of organ rejection.
22. Promote the relationship between the live donor and recipient.
23. Monitor both the donor and the recipient for depression.
24. Provide the recipient with instructions following the kidney transplantation (Box 55.9).
25. Assist the recipient to cope with the body image disturbances that occur from long-term use of immunosuppressants.
26. Advise the recipient of available support groups.

E. Graft rejection

1. Assessment (Box 55.10)
2. Hyperacute rejection
   - **a.** Hyperacute rejection occurs within 48 hours after the transplant.
   - **b.** Intervention: Removal of rejected kidney
3. Acute rejection
   - **a.** Occurs within 1 week postoperatively, but can occur any time post-transplantation
   - **b.** Intervention: Potentially reversible with increased immunosuppressive therapy

BOX 55.9 Client Instructions Following Kidney Transplantation

- Avoid prolonged periods of sitting.
- Monitor intake and output.
- Recognize the signs and symptoms of infection and rejection.
- Use medications as prescribed, do not miss any doses, and maintain immunosuppressive therapy for life.
- Avoid contact sports.
- Avoid exposure to persons with infections.
- Know the signs and symptoms that require the need to contact the primary health care provider or nephrologist.
- Ensure follow-up care.

BOX 55.10 Clinical Signs of Renal Transplant (Graft) Rejection

- Temperature higher than 100° F (37.8° C)
- Pain or tenderness over the grafted kidney
- 2- to 3-lb (0.9 to 1.4 kg) weight gain in 24 hours
- Edema
- Hypertension
- Malaise
- Elevated blood urea nitrogen and serum creatinine levels
- Decreased creatinine clearance
- Elevated white blood cell count
- Rejection indicated by ultrasound or biopsy

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 55.11 Causes of Cystitis

- Allergens or irritants, such as soaps, sprays, bubble bath, perfumed sanitary napkins
- Bladder distention
- Calculus
- Hormonal changes, influencing alterations in vaginal flora
- Indwelling urinary catheters
- Invasive urinary tract procedures
- Loss of bactericidal properties of prostatic secretions
- Microorganisms
- Poor-fitting vaginal diaphragms
- Sexual intercourse
- Synthetic underwear and pantyhose
- Urinary stasis
- Use of spermicides
- Wet bathing suits

4. Chronic rejection
   a. Occurs slowly months to years after transplant
   b. Interventions: Immunosuppressive medications and dialysis if necessary

Except in identical twin donors and recipients, the major postoperative complication following renal transplant is graft rejection.

XII. Acute Cystitis (Urinary Tract Infection)

A. Description
1. Cystitis (urinary tract infection [UTI]) is an inflammation of the bladder from an infection, obstruction of the urethra, or other irritants (Box 55.11).
2. The most common causative organisms are *Escherichia coli* and *Enterobacter, Pseudomonas,* and *Serratia* species.
3. Cystitis is more common in women, because women have a shorter urethra than men and the urethra in the woman is located close to the rectum.
4. Sexually active and pregnant women are most vulnerable to cystitis.
5. Acute cystitis should not be confused with interstitial cystitis which is a chronic condition of the bladder associated with pain and pressure of the bladder.

B. Assessment
1. Frequency and urgency
2. Burning on urination
3. Voiding in small amounts
4. Inability to void
5. Incomplete emptying of the bladder
6. Lower abdominal discomfort or back discomfort; bladder spasms
7. Cloudy, dark, foul-smelling urine
8. Hematuria
9. Malaise, chills, fever
10. WBC count greater than 11,000 mm^3 (11.0×10^9/L) on urinalysis

Altered mentation is a sign of a UTI in older adults; frequency and urgency may not be specific symptoms of UTI because of urinary elimination changes that occur with aging.

C. Interventions
1. Before administering prescribed antibiotics, obtain a urine specimen for culture and sensitivity, if prescribed, to identify bacterial growth.
2. Encourage the client to increase fluids up to 3000 mL/day, especially if the client is taking a sulfonamide; sulfonamides can form crystals in concentrated urine.
3. Administer prescribed medications, which may include analgesics, antiseptics, antispasmodics, antibiotics, and antimicrobials.
4. Maintain an acid urine pH (5.5); instruct the client about foods to consume to maintain acidic urine.
5. Provide heat to the abdomen or sitz baths for complaints of discomfort.
6. Note that if the client is prescribed an aminoglycoside, sulfonamide, or nitrofurantoin, the actions of these medications are decreased by acidic urine.
7. Use sterile technique when inserting a urinary catheter.
8. Provide meticulous perineal care for the client with an indwelling catheter.
9. Discourage caffeine products such as coffee, tea, and cola.
10. Client education
    a. Avoid alcohol.
    b. Take medications as prescribed.
    c. Take antibiotics on schedule and complete the entire course of medications as prescribed, which may be 10 to 14 days.
    d. Repeat the urine culture following treatment.
    e. Prevent recurrence of cystitis (Box 55.12).

XIII. Urethritis

A. Description
1. Inflammation of the urethra commonly associated with a sexually transmitted infection (STI); may occur with cystitis
2. Urethritis most often is caused by gonorrhea or chlamydial infection. Can also be caused by hygiene sprays, perfumed toilet paper or sanitary napkins, spermicidal jelly, UTI, or changes in the vaginal mucosal lining.

B. Assessment
1. Pain or burning on urination
2. Frequency and urgency

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 55.12 Client Instructions for Prevention of Cystitis

- Use good perineal care, wiping front to back.
- Avoid bubble baths, tub baths, and vaginal deodorants or sprays.
- Void every 2 to 3 hours.
- Wear cotton pants and avoid wearing tight clothes or pantyhose with slacks.
- Avoid sitting in a wet bathing suit for prolonged periods.
- If pregnant, void every 2 hours.
- If menopausal, use estrogen vaginal creams to restore pH.
- Use water-soluble lubricants for intercourse, especially after menopause.
- Void and drink a glass of water after intercourse.

3. Nocturia
4. Difficulty voiding
5. Clear to mucopurulent discharge from the penis
6. Lower abdominal discomfort

C. Interventions
1. Encourage fluid intake.
2. Prepare the client for testing to determine whether an STI is present.
3. Administer antibiotics as prescribed.
4. Instruct the client in the administration of sitz or tub baths.
5. If stricture occurs, prepare the client for dilation of the urethra and instillation of an antiseptic solution.
6. Instruct the client to avoid the use of perfumed toilet paper or sanitary napkins and feminine hygiene sprays.
7. Instruct the client to avoid intercourse until the symptoms subside or treatment of the STI is complete.
8. Instruct the client about STIs if this is the cause.
   a. Prevent STIs by the use of latex condoms or abstinence.
   b. All sexual partners during the 30 days before diagnosis with chlamydial infection should be notified, examined, and treated if indicated.
   c. Chlamydial infection often coexists with gonorrhea; diagnostic testing is done for both STIs.
   d. Treatment for STIs includes antibiotics as prescribed to treat the causative organism.
   e. A serious primary complication of chlamydial infection is sterility.
   f. Follow-up culture may be requested in 4 to 7 days to evaluate the effectiveness of medications.

XIV. Ureteritis

A. Description: An inflammation of the ureter commonly associated with bacterial or viral infections and pyelonephritis

B. Assessment
1. Dysuria
2. Frequent urination
3. Clear to mucopurulent penile discharge

C. Interventions
1. Treatment includes identifying and treating the underlying cause and providing symptomatic relief.
2. Metronidazole or clotrimazole may be prescribed for treating *Trichomonas* infection.
3. Nystatin or fluconazole may be prescribed for treating yeast infections.
4. Doxycycline or azithromycin may be prescribed for treating chlamydial infections.

XV. Pyelonephritis

A. Description
1. An inflammation of the renal pelvis and the parenchyma, commonly caused by bacterial invasion
2. Acute pyelonephritis often occurs after bacterial contamination of the urethra or following an invasive procedure of the urinary tract.
3. Chronic pyelonephritis most commonly occurs following chronic urinary flow obstruction with reflux.
4. *E. coli* is the most common causative bacterial organism.

B. Acute pyelonephritis
1. Acute pyelonephritis occurs as a new infection or recurs as a relapse of a previous infection.
2. It can progress to bacteremia or chronic pyelonephritis.
3. Assessment
   a. Fever and chills
   b. Tachycardia and tachypnea
   c. Nausea
   d. Flank pain on the affected side
   e. Costovertebral angle tenderness
   f. Headache
   g. Dysuria
   h. Frequency and urgency
   i. Cloudy, bloody, or foul-smelling urine
   j. Increased WBCs in the urine

C. Chronic pyelonephritis
1. A slow, progressive disease usually associated with recurrent acute attacks
2. Causes contraction of the kidney and dysfunction of the nephrons, which are replaced by scar tissue
3. Causes the ureter to become fibrotic and narrowed by strictures
4. Can lead to AKI or CKD
5. Assessment
   a. Frequently diagnosed incidentally when a client is being evaluated for hypertension
   b. Inability to conserve sodium

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

c. Poor urine-concentrating ability
d. Pyuria
e. Azotemia
f. Proteinuria

D. Interventions
1. Monitor vital signs, especially for elevated temperature.
2. Encourage fluid intake up to 3000 mL/day to reduce fever and prevent dehydration.
3. Monitor intake and output (ensure that output is a minimum of 1500 mL in 24 hours).
4. Monitor weight.
5. Encourage adequate rest.
6. Instruct the client about a high-calorie, low-protein diet.
7. Provide warm, moist compresses to the flank area to help relieve pain.
8. Encourage the client to take warm baths for pain relief.
9. Administer analgesics, antipyretics, antibiotics, urinary antiseptics, and antiemetics as prescribed.
10. Monitor for signs of AKI or CKD.
11. Encourage follow-up urine culture.

XVI. Glomerulonephritis: Refer to Chapter 38

XVII. Nephrotic Syndrome: Refer to Chapter 38

XVIII. Polycystic Kidney Disease

A. Description
1. Cyst formation and hypertrophy of the kidneys, which lead to cystic rupture, infection, formation of scar tissue, and damaged nephrons
2. There is no specific treatment to arrest the progress of the destructive cysts.
3. The ultimate result of this disease is CKD.

B. Types
1. Infantile polycystic disease: An inherited autosomal recessive trait that results in the death of the infant within a few months after birth
2. Adult polycystic disease: An autosomal dominant trait that manifests between 30 and 40 years of age and results in end-stage kidney disease

C. Assessment
1. Often asymptomatic until the age of 30 to 40 years
2. Flank, lumbar, or abdominal pain that worsens with activity and is relieved when lying down
3. Fever and chills
4. Recurrent UTIs
5. Hematuria, proteinuria, pyuria
6. Calculi
7. Hypertension
8. Palpable abdominal masses and enlarged kidneys
9. Increased abdominal girth

D. Interventions
1. Monitor for gross hematuria, which indicates cyst rupture.
2. Increase sodium and water intake because sodium loss rather than retention occurs.
3. Provide bed rest if ruptured cysts and bleeding occur.
4. Monitor pain, teach use of pain medications (avoid nonsteroidal antiinflammatory drugs [NSAIDs] and aspirin because of the risk for bleeding), and use dry heat to abdomen and flank areas for comfort when cysts are infected.
5. Prevent constipation from pressure of cysts on colon by adequate fiber in diet, stool softeners, adequate fluid intake, and exercise.
6. Prepare the client for percutaneous cyst puncture for relief of obstruction or for draining an abscess.
7. Administer antihypertensives as prescribed.
8. Prevent or treat UTIs.
9. Prepare the client for dialysis or renal transplantation.
10. Encourage the client to seek genetic counseling.
11. Provide psychological support to the client and family.
12. Provide psychosocial support and genetic counseling for family members without polycystic kidney disease who may want to donate a kidney.

XIX. Hydronephrosis

A. Description (Fig. 55.5)
1. Distention of the renal pelvis and calices caused by an obstruction of normal urine flow
2. The urine becomes trapped proximal to the obstruction.
3. The causes include calculus, tumors, scar tissue, ureter obstructions, and hypertrophy of the prostate.

B. Assessment
1. Hypertension
2. Headache
3. Colicky or dull flank pain that radiates to the groin

C. Interventions
1. Monitor vital signs frequently.
2. Monitor for fluid and electrolyte imbalances, including dehydration after the obstruction is relieved.
3. Monitor for diuresis, which can lead to fluid depletion.
4. Monitor weight daily.
5. Monitor urine for specific gravity and albumin and glucose levels.
6. Administer fluid replacement as prescribed.
7. Prepare the client for insertion of a nephrostomy tube or a surgical procedure to relieve the obstruction if prescribed.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

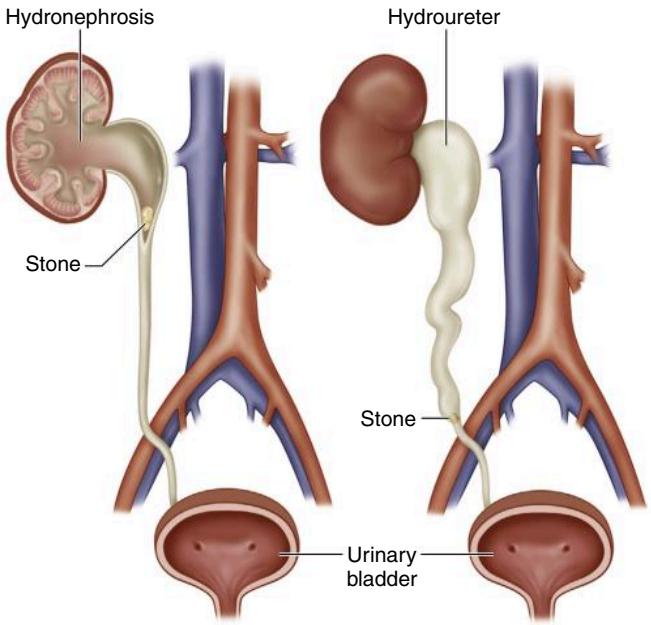

FIG. 55.5 Hydronephrosis and hydroureter.

XX. Renal Calculi

A. Description

1. Calculi are stones that can form anywhere in the urinary tract; however, the most frequent site is the kidneys.
2. Problems resulting from calculi are severe intermittent pain, obstruction, tissue trauma, secondary hemorrhage, and infection.
3. The stone can be located through radiography of the kidneys, ureters, and bladder; IV pyelography; computed tomography (CT) scanning; and renal ultrasonography.
4. A stone analysis is done after passage to determine the type of stone and assist in determining treatment.
5. **Urolithiasis** refers to the formation of urinary calculi; these form in the ureters.
6. **Nephrolithiasis** refers to the formation of kidney calculi; these form in the renal parenchyma.
7. When a calculus occludes the ureter and blocks the flow of urine, the ureter dilates, producing hydroureter (see Fig. 55.5).
8. If the obstruction is not removed, urinary stasis results in infection, impairment of renal function on the side of the blockage, hydronephrosis (see Fig. 55.5), and irreversible kidney damage.

B. Causes

1. Family history of stone formation
2. Diet high in calcium, vitamin D, protein, oxalate, purines, or alkali
3. Obstruction and urinary stasis
4. Dehydration
5. Use of diuretics, which can cause volume depletion
6. UTIs and prolonged urinary catheterization
7. Immobilization
8. Hypercalcemia and hyperparathyroidism
9. Elevated uric acid level, such as in gout

C. Assessment

1. Renal colic, which originates in the lumbar region and radiates around the side and down to the testicles in men and to the bladder in women
2. Ureteral colic, which radiates toward the genitalia and thighs
3. Sharp, severe pain of sudden onset
4. Dull, aching pain in the kidney
5. Nausea and vomiting, pallor, and diaphoresis during acute pain
6. Urinary frequency, with alternating retention
7. Signs of a UTI
8. Low-grade fever
9. High numbers of red blood cells, WBCs, and bacteria noted in the urinalysis report
10. Gross hematuria

D. Interventions

1. Monitor vital signs, especially temperature, for signs of infection.
2. Monitor intake and output.
3. Assess for fever, chills, and infection.
4. Monitor for nausea, vomiting, and diarrhea.
5. Encourage fluid intake up to 3000 mL/day, unless contraindicated, to facilitate the passage of the stone and prevent infection; monitor for obstruction.
6. Administer fluids intravenously as prescribed if unable to take fluids orally or in adequate amounts to increase the flow of urine and facilitate passage of the stone.
7. Provide warm baths and heat to the flank area (massage therapy should be avoided).

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. Administer analgesics at regularly scheduled intervals as prescribed to relieve pain.
9. Assess the client's response to pain medication.
10. Assist the client in performing relaxation techniques to assist in relieving pain.
11. Encourage client ambulation, if stable, to promote the passage of the stone.
12. Turn and reposition the immobilized client to promote passage of the stone.
13. Instruct the client in the diet restrictions specific to the stone composition if prescribed (Box 55.13).
14. Prepare the client for surgical procedures if prescribed.

BOX 55.13 Nutritional Therapy for Calculi

NOTE: Depending on the type of calculi, the diet is modified to decrease foods that are high in the substance that is the cause of the calculi.

Purine[a]

- *High:* Sardines, herring, mussels, liver, kidney, goose, venison, meat soups, sweetbreads
- *Moderate:* Chicken, salmon, crab, veal, mutton, bacon, pork, beef, ham

Calcium

- *High:* Milk, cheese, ice cream, yogurt, sauces containing milk; all beans (except green beans), lentils; fish with fine bones (e.g., sardines, kippers, herring, salmon); dried fruits, nuts; cocoa powder, chocolate, cocoa

Oxalate

- *High:* Dark roughage, spinach, rhubarb, asparagus, cabbage, tomatoes, beets, nuts, celery, parsley, runner beans; chocolate, cocoa, instant coffee, cocoa powder, tea; Worcestershire sauce

[a]Uric acid is a waste product from purine in food.

Adapted from Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1039.

⚠ For the client with renal calculi, strain all urine for the presence of stones and send the stones to the laboratory for analysis.

XXI. Treatment Options for Renal Calculi (Fig. 55.6)

A. Cystoscopy
1. Cystoscopy may be done for stones in the bladder or lower ureter.
2. One or two ureteral catheters are inserted past the stone.
3. The catheters are left in place for 24 hours to drain the urine trapped proximal to the stone and to dilate the ureter.
4. A continuous chemical irrigation may be prescribed to dissolve the stone.

B. Extracorporeal shock wave lithotripsy (ESWL)
1. A noninvasive mechanical procedure for breaking up stones located in the kidney or upper ureter so that they can pass spontaneously or be removed by other methods
2. A stent may be placed to facilitate passing stone fragments.
3. Fluoroscopy is used to visualize the stone, and ultrasonic waves are delivered to the area of the stone to disintegrate it.
4. The stones are passed in the urine within a few days.
5. The client is taught to watch for signs of urinary obstruction, bleeding, or hematoma formation.
6. Instruct the client to increase fluid intake to flush out the stone fragments.

C. Percutaneous lithotripsy
1. An invasive procedure in which a guide is inserted under fluoroscopy near the area of the stone; an ultrasonic wave is aimed at the stone to break it into fragments.
2. Percutaneous lithotripsy may be performed via cystoscopy or nephroscopy (a small flank incision is needed for nephroscopy).

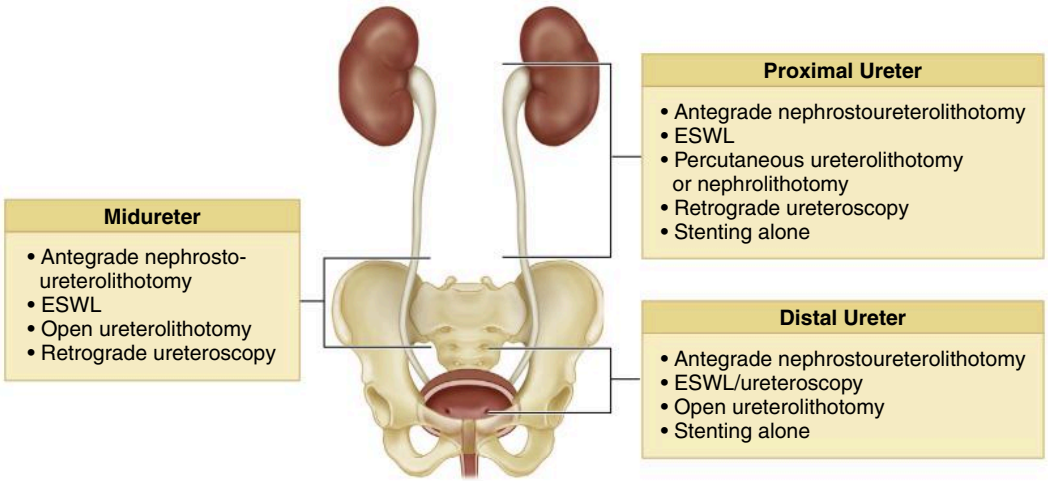

FIG. 55.6 Treatment options for ureteral stones. *ESWL,* Extracorporeal shock wave lithotripsy.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. The client might have an indwelling urinary catheter.
4. A nephrostomy tube may be placed to administer chemical irrigations to break up the stone; the nephrostomy tube may remain in place for 1 to 5 days.
5. Encourage the client to drink 3000 to 4000 mL of fluid per day as prescribed following the procedure.
6. Instruct the client to monitor for complications of infection, hemorrhage, and extravasation of fluid into the retroperitoneal cavity.

D. Ureterolithotomy
1. An open surgical procedure performed if lithotripsy is not effective for removal of a stone in the ureter
2. An incision is made through the lower abdomen or flank and then into the ureter to remove the stone.
3. The client may have a drain, ureteral stent catheter, and/or indwelling bladder catheter.

E. Pyelolithotomy and nephrolithotomy
1. Pyelolithotomy is an incision into the renal pelvis to remove a stone; a large flank incision is required, and the client may have a drain and indwelling bladder catheter.
2. Nephrolithotomy is an incision into the kidney made to remove a stone; a large flank incision is required, and the client may have a nephrostomy tube and an indwelling bladder catheter.

F. Partial or total nephrectomy
1. Performed for extensive kidney damage, renal infection, severe obstruction from stones or tumors, and prevention of stone recurrence
2. Monitor the incision, particularly if a drain is in place, because it will drain large amounts of urine.
3. Protect the skin from urinary drainage, changing dressings frequently if necessary; place an ostomy pouch over the drain to protect the skin if urinary drainage is excessive.
4. Monitor the nephrostomy tube, which may be attached to a drainage bag, for a continuous flow of urine.
5. Do not irrigate the nephrostomy or bladder catheters unless specifically prescribed.
6. Encourage fluid intake to ensure a urine output of 2500 to 3000 mL/day or more as prescribed.

XXII. Kidney Tumors

A. Description
1. Kidney tumors may be benign or malignant, bilateral or unilateral.
2. Common sites of metastasis of malignant tumors include bone, lungs, liver, spleen, and the other kidney.
3. The exact cause of renal carcinoma is unknown.

B. Assessment
1. Dull flank pain
2. Palpable renal mass
3. Painless gross hematuria

C. Radical nephrectomy
1. Description
   a. Surgical removal of the entire kidney, adjacent adrenal gland, and renal artery and vein
   b. Radiation therapy and possibly chemotherapy may follow radical nephrectomy.
   c. Before surgery, radiation may be used to embolize (occlude) the arteries supplying the kidney to reduce bleeding during nephrectomy.
2. Postoperative interventions
   a. Monitor vital signs for signs of bleeding (hypotension and tachycardia).
   b. Monitor for abdominal distention, decreases in urinary output, and alterations in level of consciousness as signs of bleeding; check the bed linens under the client for bleeding.
   c. Monitor for signs of adrenal insufficiency, which include a large urinary output followed by hypotension and subsequent oliguria.
   d. Administer fluids and packed red blood cells intravenously as prescribed.
   e. Monitor intake and output and daily weight.
   f. Monitor for a urinary output of 30 to 50 mL/hr to ensure adequate renal function.
   g. Maintain the client in a semi-Fowler's position.
   h. If a nephrostomy tube is in place, do not irrigate (unless specifically prescribed) or manipulate the tube.

XXIII. Epididymitis

A. Description
1. Acute or chronic inflammation of the epididymis that occurs as a result of a UTI, STI, prostatitis, or long-term use of a bladder catheter
2. The infective organism travels upward through the urethra and ejaculatory duct and along the vas deferens to the epididymis.

B. Assessment
1. Scrotal and groin pain
2. Swelling in the scrotum and groin
3. Pus and bacteria in the urine
4. Fever and chills
5. Abscess development

C. Interventions
1. Encourage fluid intake.
2. Encourage bed rest with the scrotum elevated to prevent traction on the spermatic cord, facilitate drainage, and relieve pain.
3. Instruct the client in the intermittent application of cold compresses to the scrotum.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Instruct the client in the use of tub or sitz baths.
5. Instruct the client in the administration of antibiotics for self and sexual partner if the cause is chlamydial or gonorrheal infection.
6. Instruct the client to avoid lifting, straining, and sexual contact until the infection subsides.
7. Instruct the client to limit the force of the urine stream, because organisms can be forced into the vas deferens and epididymis from strain or pressure during voiding.
8. Teach the client that condom use can help prevent urethritis and epididymitis.
9. Teach the client measures to prevent UTI or STI recurrence.

XXIV. Prostatitis

A. Description
1. Inflammation of the prostate gland commonly caused by an infectious agent; may be acute or chronic
2. The bacterial type occurs as a result of the organism reaching the prostate via the urethra, bladder, bloodstream, or lymphatic channels.
3. The abacterial type usually occurs following a viral illness or a decrease in sexual activity.

B. Assessment
1. Bacterial prostatitis
   a. Client becomes acutely ill.
   b. Fever and chills
   c. Frequency and urgency of urination; dysuria
   d. Perineal and low back pain
   e. Urethral discharge
   f. Prostate is tender, indurated, and warm to the touch.
   g. Urethral discharge on palpation of prostate
   h. WBCs are found in prostatic secretions.
   i. Urine culture is usually positive for gram-negative bacteria, especially after prostate massage.
2. Abacterial prostatitis (most common form of chronic prostatitis)
   a. Backache
   b. Dysuria
   c. Perineal pain
   d. Frequency
   e. Hematuria
   f. Irregularly enlarged, firm, and tender prostate

C. Interventions
1. Encourage adequate fluid intake.
2. Instruct the client in the use of tub or sitz baths to promote comfort.
3. Administer antibiotics, analgesics, antispasmodics, and stool softeners as prescribed.
4. Inform the client of activities to drain the prostate, such as intercourse, masturbation, and prostatic massage.
5. Instruct the client to avoid spicy foods, coffee, alcohol, prolonged automobile rides, and sexual intercourse during an acute inflammation.

XXV. Benign Prostatic Hypertrophy (Hyperplasia)

A. Description
1. Benign prostatic hypertrophy (benign prostatic hyperplasia; BPH) is a slow enlargement of the prostate gland, with hypertrophy and hyperplasia of normal tissue.
2. Enlargement compresses the urethra, resulting in partial or complete obstruction.
3. Usually occurs in those older than 50 years

B. Assessment
1. Diminished size and force of urinary stream (early sign of BPH)
2. Urinary urgency and frequency
3. Nocturia
4. Inability to start (hesitancy) or continue a urinary stream
5. Feelings of incomplete bladder emptying
6. Postvoid dribbling from overflow incontinence (later sign)
7. Urinary retention and bladder distention
8. Hematuria
9. Urinary stasis and UTIs
10. Dysuria and bladder pain

C. Interventions
1. Encourage fluid intake of up to 2000 to 3000 mL/day unless contraindicated.
2. Prepare for urinary catheterization to drain the bladder and prevent distention.
3. Avoid administering medications that cause urinary retention, such as anticholinergics, antihistamines, decongestants, and antidepressants.
4. Administer medications as prescribed to shrink the prostate gland and improve urine flow.
5. Administer medications as prescribed to relax prostatic smooth muscle and improve urine flow.
6. Instruct the client to decrease intake of caffeine and artificial sweeteners and limit spicy or acidic foods.
7. Instruct the client to follow a timed voiding schedule.
8. Prepare the client for surgery or invasive procedures as prescribed (see Chapter 45, Figs. 45.6 and 45.7).

D. Surgical interventions and postoperative care (see Chapter 45)

XXVI. Bladder Cancer: Refer to Chapter 45

XXVII. Bladder Trauma

A. Description
1. Occurs following a blunt or penetrating injury to the lower abdomen

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Blunt trauma causes compression of the abdominal wall and bladder.
3. Penetrating wounds occur as a result of a stabbing, gunshot wound, or other objects piercing the abdominal wall.
4. A fractured pelvis that causes bone fragments to puncture the bladder is a common cause of bladder trauma.

B. Assessment
1. Anuria
2. Hematuria
3. Pain below the level of the umbilicus; can radiate to the shoulders
4. Nausea and vomiting

C. Interventions
1. Monitor vital signs.
2. Monitor for hematuria, bleeding, and signs of shock.
3. Maintain bed rest.
4. If blood is seen at the meatus, avoid urinary catheterization until a retrograde ureterogram can be obtained.
5. Prepare the client for insertion of a suprapubic catheter to aid in urinary drainage if prescribed.
6. Prepare the client for surgical repair of the laceration if indicated.

PRACTICE QUESTIONS

1. A client with acute kidney injury has a serum potassium level of 7.0 mEq/L (7.0 mmol/L). The nurse would plan which actions as a **priority? Select all that apply.**
- ❑ 1. Place the client on a cardiac monitor.
- ❑ 2. Notify the primary health care provider (PHCP).
- ❑ 3. Put the client on NPO (nothing by mouth) status except for ice chips.
- ❑ 4. Review the client's medications to determine whether any contain or retain potassium.
- ❑ 5. Allow an extra 500 mL of intravenous fluid intake to dilute the electrolyte concentration.

2. A client with chronic kidney disease being hemodialyzed suddenly becomes short of breath and complains of chest pain. The client is tachycardic, pale, and anxious, and the nurse suspects air embolism. What are the **priority** nursing actions? **Select all that apply.**
- ❑ 1. Administer oxygen to the client.
- ❑ 2. Continue dialysis at a slower rate after checking the lines for air.
- ❑ 3. Notify the primary health care provider (PHCP) and Rapid Response Team.
- ❑ 4. Stop dialysis, and turn the client on the left side with head lower than feet.
- ❑ 5. Bolus the client with 500 mL of normal saline to break up the air embolus.

3. A client arrives at the emergency department with complaints of low abdominal pain and hematuria. The client is afebrile. The nurse **next** assesses the client to determine a history of which condition?
1. Pyelonephritis
2. Glomerulonephritis
3. Recent trauma to the bladder or abdomen
4. Renal cancer in the client's family

4. The nurse discusses plans for future treatment options with a client with symptomatic polycystic kidney disease. Which treatment(s) would be included in this discussion? **Select all that apply.**
- ❑ 1. Hemodialysis
- ❑ 2. Peritoneal dialysis
- ❑ 3. Kidney transplant
- ❑ 4. Bilateral nephrectomy
- ❑ 5. Intense immunosuppression therapy

5. A client is admitted to the emergency department following a fall from a horse, and the primary health care provider (PHCP) prescribes insertion of a urinary catheter. While preparing for the procedure, the nurse notes blood at the urinary meatus. The nurse would take which action?
1. Notify the PHCP before performing the catheterization.
2. Use a small-sized catheter and an anesthetic gel as a lubricant.
3. Administer parenteral pain medication before inserting the catheter.
4. Clean the meatus with soap and water before opening the catheterization kit.

6. The nurse is assessing the patency of a client's left arm arteriovenous fistula prior to initiating hemodialysis. Which finding indicates that the fistula is patent?
1. Palpation of a thrill over the fistula
2. Presence of a radial pulse in the left wrist
3. Visualization of enlarged blood vessels at the fistula site
4. Capillary refill less than 3 seconds in the nail beds of the fingers on the left hand

7. A client has a tentative diagnosis of urethritis. The nurse would assess the client for which manifestation of the disorder?
1. Hematuria and pyuria
2. Dysuria and proteinuria
3. Hematuria and urgency
4. Dysuria and penile discharge

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. The nurse is assessing a client with epididymitis. The nurse anticipates which findings on physical examination?
   1. Fever, diarrhea, groin pain, and ecchymosis
   2. Nausea, painful scrotal edema, and ecchymosis
   3. Fever, nausea, vomiting, and painful scrotal edema
   4. Diarrhea, groin pain, testicular torsion, and scrotal edema

9. A client complains of fever, perineal pain, urinary urgency, frequency, and dysuria. To assess whether the client's problem is related to bacterial prostatitis, the nurse reviews the results of the prostate examination for which characteristic of this disorder?
   1. Soft and swollen prostate gland
   2. Swollen and boggy prostate gland
   3. Tender and edematous prostate gland
   4. Tender, indurated prostate gland that is warm to the touch

10. The nurse is collecting data from a client. Which symptom described by the client is characteristic of an **early** symptom of benign prostatic hyperplasia?
    1. Nocturia
    2. Scrotal edema
    3. Occasional constipation
    4. Decreased force in the stream of urine

11. The nurse monitoring a client receiving peritoneal dialysis notes that the client's outflow is less than the inflow. Which actions would the nurse take? **Select all that apply.**
    - ❑ 1. Check the level of the drainage bag.
    - ❑ 2. Reposition the client to the side.
    - ❑ 3. Place the client in good body alignment.
    - ❑ 4. Check the peritoneal dialysis system for kinks.
    - ❑ 5. Contact the primary health care provider (PHCP).
    - ❑ 6. Increase the flow rate of the peritoneal dialysis solution.

12. A hemodialysis client with a left arm fistula is at risk for arterial steal syndrome. The nurse would assess for which manifestations of this complication?
    1. Warmth, redness, and pain in the left hand
    2. Ecchymosis and audible bruit over the fistula
    3. Edema and reddish discoloration of the left arm
    4. Pallor, diminished pulse, and pain in the left hand

13. The nurse is reviewing a client's record and notes that the primary health care provider has documented that the client has chronic kidney disease. On review of the laboratory results, the nurse **most likely** would expect to note which finding?
    1. Elevated creatinine level
    2. Decreased hemoglobin level
    3. Decreased red blood cell count
    4. Increased number of white blood cells in the urine

14. A client with chronic kidney disease returns to the nursing unit following a hemodialysis treatment. On assessment, the nurse notes that the client's temperature is 101.2° F (38.5° C). Which nursing action is **most appropriate**?
    1. Encourage fluid intake.
    2. Continue to monitor vital signs.
    3. Notify the primary health care provider.
    4. Monitor the site of the shunt for infection.

15. The nurse is performing an assessment on a client who has returned from the dialysis unit following hemodialysis. The client is complaining of headache and nausea and is extremely restless. Which is the **priority** nursing action?
    1. Monitor the client.
    2. Elevate the head of the bed.
    3. Assess the fistula site and dressing.
    4. Notify the primary health care provider (PHCP).

16. A client with severe back pain and hematuria is found to have hydronephrosis due to urolithiasis. The nurse anticipates that which treatment will be done to relieve the obstruction? **Select all that apply.**
    - ❑ 1. Peritoneal dialysis
    - ❑ 2. Analysis of the urinary stone
    - ❑ 3. Intravenous opioid analgesics
    - ❑ 4. Insertion of a nephrostomy tube
    - ❑ 5. Placement of a ureteral stent with ureteroscopy

17. The nurse is instructing a client with diabetes mellitus about peritoneal dialysis. The nurse tells the client that it is important to maintain the prescribed dwell time for the dialysis because of the risk of which complication?
    1. Peritonitis
    2. Hyperglycemia
    3. Hyperphosphatemia
    4. Disequilibrium syndrome

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

18. A week after kidney transplantation, a client develops a temperature of 101° F (38.3° C), the blood pressure is elevated, and there is tenderness over the transplanted kidney. The serum creatinine is rising, and urine output is decreased. The x-ray indicates that the transplanted kidney is enlarged. Based on these assessment findings, the nurse anticipates which treatment?
1. Antibiotic therapy
2. Peritoneal dialysis
3. Removal of the transplanted kidney
4. Increased immunosuppression therapy

19. A client is admitted to the hospital with a diagnosis of benign prostatic hyperplasia, and a transurethral resection of the prostate is performed. Four hours after surgery, the nurse takes the client's vital signs and empties the urinary drainage bag. Which assessment finding indicates the need to notify the primary health care provider (PHCP)?
1. Red, bloody urine
2. Pain rated as 2 on a 0 to 10 pain scale
3. Urinary output of 200 mL higher than intake
4. Blood pressure, 100/50 mm Hg; pulse, 130 beats per minute

20. The client newly diagnosed with chronic kidney disease recently has begun hemodialysis. Knowing that the client is at risk for disequilibrium syndrome, the nurse would assess the client during dialysis for which associated manifestations?
1. Hypertension, tachycardia, and fever
2. Hypotension, bradycardia, and hypothermia
3. Restlessness, irritability, and generalized weakness
4. Headache, deteriorating level of consciousness, and twitching

ANSWERS

1. *Answer:* 1, 2, 4
Rationale: The normal potassium level is 3.5 to 5.0 mEq/L (3.5 to 5.0 mmol/L). A potassium level of 7.0 mEq/L (7.0 mmol/L) is elevated. The client with hyperkalemia is at risk of developing cardiac dysrhythmias and cardiac arrest. Because of this, the client would be placed on a cardiac monitor. The nurse needs to notify the PHCP and also review medications to determine whether any contain potassium or are potassium sparing. The client does not need to be put on NPO status. Fluid intake is not increased because it contributes to fluid overload and would not affect the serum potassium level significantly.
Test-Taking Strategy: Note the strategic word, *priority.* First, note that the potassium level is significantly elevated to select options 1 and 4. Next, recalling that an elevated potassium can lead to life-threatening dysrhythmias will direct you to select option 2.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1378-1379.

2. *Answer:* 1, 3, 4
Rationale: If the client experiences air embolus during hemodialysis, the nurse would terminate dialysis immediately, position the client so that the air embolus is in the right side of the heart, notify the PHCP and Rapid Response Team, and administer oxygen as needed. Slowing the dialysis treatment or giving an intravenous bolus will not correct the air embolism or prevent complications.
Test-Taking Strategy: Note the strategic word, *priority.* Recall that air embolism is an emergency situation that affects the cardiopulmonary system suddenly and profoundly. Select the options that deal with the problem, supply oxygen, and get needed assistance.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 294; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 217-218.

3. *Answer:* 3
Rationale: Bladder trauma or injury needs to be considered or suspected in the client with low abdominal pain and hematuria. Glomerulonephritis and pyelonephritis would be accompanied by fever and are thus not applicable to the client described in this question. Renal cancer would not cause pain that is felt in the low abdomen; rather, the pain would be in the flank area.
Test-Taking Strategy: Note the strategic word, *next.* Eliminate options 1 and 2 because they are comparable or alike, knowing that any inflammatory disease or infection is accompanied by fever. Because this client is afebrile, these are not possible options. Use knowledge of anatomy and pain assessment to select the correct option. Pain from renal cancer is a later finding and is localized in the flank area.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1040-1041.

4. *Answer:* 1, 3, 4
Rationale: Polycystic kidney disease is a genetic familial disease in which the kidneys enlarge with cysts that rupture and scar the kidney, eventually resulting in end-stage renal disease. Treatment options include hemodialysis or kidney transplant. Clients usually undergo bilateral nephrectomy to remove the

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

large, painful, cyst-filled kidneys. Peritoneal dialysis is not a treatment option due to the cysts. The condition does not respond to immunosuppression.
Test-Taking Strategy: Focus on the **subject,** treatment options for polycystic kidney disease. Think about the pathophysiology associated with this condition and recall that the condition results in end-stage renal disease. This will direct you to the correct options.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1358, 1395, 1405.

5. *Answer:* 1
Rationale: The presence of blood at the urinary meatus may indicate urethral trauma or disruption. The nurse notifies the PHCP, knowing that the client would not be catheterized until the cause of the bleeding is determined by diagnostic testing. The other options include performing the catheterization procedure and therefore are incorrect.
Test-Taking Strategy: Focus on the **subject,** the complications associated with a traumatic fall. Noting the words *blood at the urinary meatus* suggests internal trauma that could be further aggravated by the catheterization.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1370-1371.

6. *Answer:* 1
Rationale: The nurse assesses the patency of the fistula by palpating for the presence of a thrill or auscultating for a bruit. The presence of a thrill and bruit indicates patency of the fistula. Enlarged visible blood vessels at the fistula site are a normal observation but are not indicative of fistula patency. Although the presence of a radial pulse in the left wrist and capillary refill of less than 3 seconds in the nail beds of the fingers on the left hand indicate adequate circulation to the hand, they do not assess fistula patency.
Test-Taking Strategy: Eliminate options 2 and 4 first because they are **comparable or alike,** and assess for adequate circulation in the distal portion of the extremity (not the fistula). Enlarged blood vessels occur when the fistula is created. Select option 1, because a thrill indicates blood flow and patency of the fistula.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp.1397-1399.

7. *Answer:* 4
Rationale: Urethritis often results from chlamydial infection and is characterized by dysuria, which is accompanied by a clear to mucopurulent discharge. Because this disorder often coexists with gonorrhea, diagnostic tests are done for both and include culture and rapid assays. Hematuria is not associated with urethritis. Proteinuria is associated with kidney dysfunction.
Test-Taking Strategy: Focus on the **subject,** manifestations of urethritis. Recalling that urethritis generally is accompanied by dysuria will assist you in eliminating options 1 and 3. Knowing that the problem originates in the urethra, not the kidneys, will assist you in eliminating option 2, because proteinuria indicates a problem with kidney function.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1343-1344.

8. *Answer:* 3
Rationale: Typical signs and symptoms of epididymitis include scrotal pain and edema, which often are accompanied by fever, nausea and vomiting, and chills. Epididymitis most often is caused by infection, although sometimes it can be caused by trauma. The remaining options do not present all of the accurate manifestations.
Test-Taking Strategy: Any disorder that ends in *-itis* results from inflammation or infection. Therefore, an expected finding would be elevated temperature. With this in mind, eliminate options 2 and 4 because they are **comparable or alike** and do not contain fever as part of the option. Knowing that ecchymosis results from bleeding, which is not part of this clinical picture, directs you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1269, 1271.

9. *Answer:* 4
Rationale: The client with bacterial prostatitis has a swollen and tender prostate gland that is also warm to the touch, firm, and indurated. Systemic symptoms include fever with chills, perineal and low back pain, and signs of urinary tract infection, which often accompany the disorder.
Test-Taking Strategy: Focus on the **subject,** manifestations of bacterial prostatitis. Begin to answer this question by reasoning that inflammation of the prostate gland would cause the area to be tender. This would allow you to eliminate options 1 and 2. Recalling that inflammation is accompanied by local warmth will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1269.

10. *Answer:* 4
Rationale: Decreased force in the stream of urine is an early symptom of benign prostatic hyperplasia. The stream later becomes weak and dribbling. The client then may develop hematuria, frequency, urgency, urge incontinence, and nocturia. If untreated, complete obstruction and urinary retention can occur. Constipation or scrotal edema is not associated with benign prostatic hyperplasia.
Test-Taking Strategy: Note the **strategic word,** *early*. Also, if you know that benign prostatic hyperplasia can lead to urinary obstruction, look for the option that identifies the least severe symptom.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1470.

Telegram & Insta: NCLEX_RN_Edu

11. *Answer:* 1, 2, 3, 4
Rationale: If outflow drainage is inadequate, the nurse attempts to stimulate outflow by changing the client's position. Turning the client to the side or making sure that the client is in good body alignment may assist with outflow drainage. The drainage bag needs to be lower than the client's abdomen to enhance gravity drainage. The connecting tubing and peritoneal dialysis system are also checked for kinks or twisting, and the clamps on the system are checked to ensure that they are open. There is no reason to contact the PHCP. Increasing the flow rate would not be done and also is not associated with the amount of outflow solution.
Test-Taking Strategy: Focus on the **subject,** outflow is less than inflow, and use the principles related to gravity flow and preventing obstruction to flow to answer this question. This will assist in determining the correct interventions.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1404.

12. *Answer:* 4
Rationale: Steal syndrome results from vascular insufficiency after creation of a fistula. The client exhibits pallor and a diminished pulse distal to the fistula. The client also complains of pain distal to the fistula, caused by tissue ischemia. Warmth and redness probably would characterize a problem with infection. Ecchymosis and a bruit are normal findings for a fistula.
Test-Taking Strategy: Focus on the **subject,** arterial steal syndrome. Eliminate signs associated with infection or normal fistula findings. Recalling that steal syndrome results from vascular insufficiency after creation of a fistula will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1399.

13. *Answer:* 1
Rationale: The creatinine level is the most specific laboratory test to determine renal function. The creatinine level increases when at least 50% of renal function is lost. A decreased hemoglobin level and red blood cell count are associated with anemia or blood loss and not specifically with decreased renal function. Increased white blood cells in the urine are noted with urinary tract infection.
Test-Taking Strategy: Note the **strategic words,** *most likely.* Recalling the relationship between the creatinine level and renal function will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1379.

14. *Answer:* 3
Rationale: A temperature of 101.2° F (38.5° C) is significantly elevated and may indicate infection. The nurse would notify the primary health care provider (PHCP). Dialysis clients cannot have fluid intake encouraged. Vital signs and the shunt site should be monitored, but the PHCP needs to be notified first.
Test-Taking Strategy: Note the **strategic words,** *most appropriate.* Focus on the **data in the question.** Note the temperature elevation. This warrants notification of the PHCP, who may prescribe diagnostic tests or medications.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 669, 675-676.

15. *Answer:* 4
Rationale: Disequilibrium syndrome may be caused by rapid removal of solutes from the body during hemodialysis. These changes can cause cerebral edema that leads to increased intracranial pressure. The client is exhibiting early signs and symptoms of disequilibrium syndrome, and appropriate treatments with anticonvulsive medications and barbiturates may be necessary to prevent a life-threatening situation. The PHCP must be notified. Monitoring the client, elevating the head of the bed, and assessing the fistula site are correct actions, but the priority action is to notify the PHCP.
Test-Taking Strategy: Note the **strategic word,** *priority*, and focus on the client's signs and symptoms. Determine if an **abnormality exists.** Recalling the serious complications associated with hemodialysis such as disequilibrium syndrome will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1400-1401.

16. *Answer:* 4, 5
Rationale: Urolithiasis is the condition that occurs when a stone forms in the urinary system. Hydronephrosis develops when the stone has blocked the ureter and urine backs up and dilates and damages the kidney. Priority treatment is to allow the urine to drain and relieve the obstruction in the ureter. This is accomplished by placement of a percutaneous nephrostomy tube to drain urine from the kidney and placement of a ureteral stent to keep the ureter open. Peritoneal dialysis is not needed, since the kidney is functioning. Stone analysis will be done later when the stone has been retrieved and analyzed. Opioid analgesics are necessary for pain relief but do not treat the obstruction.
Test-Taking Strategy: Focus on the **subject,** treatment to relieve the obstruction. Think about what each option will accomplish. Eliminate the options that do not address the obstruction.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1347-1348.

17. *Answer:* 2
Rationale: An extended dwell time increases the risk of hyperglycemia in the client with diabetes mellitus as a result of absorption of glucose from the dialysate and electrolyte changes. Diabetic clients may require extra insulin when receiving peritoneal dialysis. Peritonitis is a risk associated with breaks in aseptic technique. Hyperphosphatemia is an

Telegram & Insta: NCLEX_RN_Edu

electrolyte imbalance that occurs with renal dysfunction. Disequilibrium syndrome is a complication associated with hemodialysis.
Test-Taking Strategy: Focus on the **subject,** a complication associated with an extended dwell time. Noting the client's diagnosis and recalling that the dialysate solution contains glucose will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1405.

18. *Answer:* 4
Rationale: Acute rejection most often occurs within 1 week after transplantation but can occur any time post-transplantation. Clinical manifestations include fever, malaise, elevated white blood cell count, acute hypertension, graft tenderness, and manifestations of deteriorating renal function. Treatment consists of increasing immunosuppressive therapy. Antibiotics are used to treat infection, but the symptoms described better suit acute rejection. Peritoneal dialysis cannot be used with a newly transplanted kidney due to the recent surgery. Removal of the transplanted kidney is indicated with hyperacute rejection, which occurs within 48 hours of the transplant surgery.
Test-Taking Strategy: Note the words *a week after kidney transplantation*. Focus on the **data in the question** and the time frame and symptoms, which describe acute rejection. Recall the treatment for *acute* rejection to direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1407-1408.

19. *Answer:* 4
Rationale: Frank bleeding (arterial or venous) may occur during the first day after surgery. Some hematuria is usual for several days after surgery. A urinary output of 200 mL more than intake is adequate. A client pain rating of 2 on a 0 to 10 scale indicates adequate pain control. A rapid pulse with a low blood pressure is a potential sign of excessive blood loss. The PHCP needs to be notified.
Test-Taking Strategy: Focus on the **subject,** the need to notify the PHCP, and determine whether an **abnormality exists.** Think about the expected findings following this procedure and note that the vital signs are not within the normal range and could indicate excessive blood loss.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1477-1478.

20. *Answer:* 4
Rationale: Disequilibrium syndrome is characterized by headache, mental confusion, decreasing level of consciousness, nausea, vomiting, twitching, and possible seizure activity. Disequilibrium syndrome is caused by rapid removal of solutes from the body during hemodialysis. At the same time, the blood–brain barrier interferes with the efficient removal of wastes from brain tissue. As a result, water goes into cerebral cells because of the osmotic gradient, causing increased intracranial pressure and onset of symptoms. The syndrome most often occurs in clients who are new to dialysis and is prevented by dialyzing for shorter times or at reduced blood flow rates. Tachycardia and fever are associated with infection. Generalized weakness is associated with low blood pressure and anemia. Restlessness and irritability are not associated with disequilibrium syndrome. The blood pressure may increase if increased intracranial pressure results. Bradycardia may or may not result and hypothermia is not associated with this syndrome.
Test-Taking Strategy: Focus on the **subject,** disequilibrium syndrome. Think about the pathophysiology and that brain cells are responsive to changes in osmolarity. This will assist you to choose the correct option describing neurological symptoms.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1401.

CHAPTER 56

Renal and Urinary Medications

Contributors: Erica Shae Lee, MSN-Ed, RN
James Guilbault, PharmD, BS, RPh

Telegram & Insta: NCLEX_RN_Edu

PRIORITY CONCEPTS Elimination; Safety

I. Urinary Tract Antiseptics

A. Description

1. Urinary tract antiseptics inhibit the growth of bacteria in the urine (Box 56.1).

2. Act as disinfectants within the urinary tract

3. Used to treat acute cystitis or urinary tract infections (UTIs)

4. Urinary tract antiseptics do not achieve effective antibacterial concentrations in blood or tissues and therefore cannot be used for infections outside the urinary tract.

B. Side and adverse effects and nursing considerations

1. Fosfomycin

a. The medication is available as granules that must be dissolved; instruct the client to mix the contents of a package in about ½ cup (120 mL) of cold water, stir well, and drink all of the liquid.

b. Medications that increase gastrointestinal motility reduce the absorption of fosfomycin.

2. Methenamine

a. Used to treat chronic UTIs but not recommended for acute infections

b. Administer after meals and at bedtime to minimize gastric distress.

c. Chronic high-dose therapy can cause bladder irritation.

d. Methenamine can cause crystalluria and should not be used in clients with renal impairment.

e. Decomposition of the medication generates ammonia; therefore, it should not be used for clients with liver dysfunction.

f. Methenamine requires acidic urine with a pH of 5.5 or lower.

g. Increasing fluid intake reduces antibacterial effects by diluting the medication and raising urine pH.

h. Methenamine should not be combined with sulfonamides because of the risk of crystalluria and urinary tract injury.

i. Clients taking this medication need to avoid alkalinizing agents, including over-the-counter antacids containing sodium bicarbonate or sodium carbonate.

3. Nitrofurantoin

a. Gastrointestinal effects include anorexia, nausea, vomiting, and diarrhea; administration with milk or meals minimizes gastrointestinal distress.

b. Pulmonary reactions include dyspnea, chest pain, chills, fever, cough, and alveolar infiltrates; these resolve in 2 to 4 days following cessation of treatment.

c. Hematological effects include agranulocytosis, leukopenia, thrombocytopenia, and megaloblastic anemia.

d. Peripheral neuropathy effects include muscle weakness, tingling sensations, and numbness.

e. Neurological effects include headache, vertigo, drowsiness, and nystagmus.

f. Allergic reactions include anaphylaxis, hives, rash, and tingling sensations around the mouth.

g. Nitrofurantoin may impart a harmless brown color to the urine.

h. Nitrofurantoin is contraindicated in clients with renal impairment.

i. Instruct the client in expected side and adverse effects, signs warranting notification of the primary health care provider (PHCP), and not to take nitrofurantoin with antacids.

Telegram & Insta: NCLEX_RN_Edu

BOX 56.1 Urinary Tract Antiseptics

- Amoxicillin
- Cefixime
- Fosfomycin
- Methenamine
- Nitrofurantoin

BOX 56.2 Fluoroquinolones

- Ciprofloxacin
- Levofloxacin
- Ofloxacin
- Gatifloxacin

II. Fluoroquinolones (Box 56.2) (see Clinical Judgment: Recognize Cues Box)

A. Description: Suppress bacterial growth by inhibiting an enzyme necessary for DNA synthesis; active against a broad spectrum of microbes

B. Side and adverse effects and nursing considerations

1. Can cause dizziness, drowsiness, gastric distress, diarrhea, vaginitis, nausea, and vomiting
2. Adverse effects include psychoses, hallucinations, confusion, tremors, hypersensitivity, and interstitial nephritis.

⚠ With fluoroquinolones, there is an increased risk for tendinitis and tendon rupture. The Achilles tendon is most often involved, but the shoulder and hand tendons can also be affected. Clients at increased risk are those over the age of 60 years, those taking corticosteroids, and clients who have undergone organ transplant.

3. Fluoroquinolones should be used with caution in clients with hepatic, renal, or central nervous system (CNS) disorders.
4. Monitor client for side and adverse effects.
5. Ciprofloxacin and ofloxacin may be taken with or without food.
6. Intravenously administered ciprofloxacin and ofloxacin are infused slowly over 60 minutes to minimize discomfort and vein irritation.
7. Advise the client to report dizziness, lightheadedness, visual disturbances, increased light sensitivity, and feelings of depression, because these signs could indicate CNS toxicity.
8. Avoid ultraviolet light and sun exposure using protective clothing and sunscreen.
9. Inform the client of signs of hepatic and renal toxicity and the importance of reporting these signs to the PHCP.

⚠ Administer oral fluoroquinolones with a full glass of water, and ensure that the client maintains a urine output of at least 1200 to 1500 mL daily to minimize the development of crystalluria.

CLINICAL JUDGMENT: RECOGNIZE CUES

A client with acute cystitis has been prescribed ciprofloxacin. The client calls the nurse at the health care clinic to report dizziness and light-headedness and that vision is blurred. The client tells the nurse about feeling really depressed and needing to keep all of the shades and curtains closed in the house because the light is really bothering the eyes. The nurse recognizes that the client may be experiencing central nervous system effects from the medication. The nurse would instruct the client to withhold the medication and contact the primary health care provider (PHCP).

BOX 56.3 Sulfonamides

- Sulfadiazine
- Sulfasalazine
- Sulfacetamide
- Trimethoprim-sulfamethoxazole

III. Sulfonamides (Box 56.3)

A. Description: Suppress bacterial growth by inhibiting the synthesis of folic acid; active against a broad spectrum of microbes; used primarily to treat acute UTIs

B. Side and adverse effects and nursing considerations

1. Hypersensitivity reactions include rash, fever, and photosensitivity.
2. Stevens-Johnson syndrome, the most severe hypersensitivity response, produces symptoms that include widespread lesions of the skin and mucous membranes, fever, malaise, and toxemia.
3. Sulfonamides can cause hemolytic anemia, agranulocytosis, leukopenia, and thrombocytopenia; instruct the client to notify the PHCP if sore throat or fever occurs.
4. Administer sulfonamides with caution in clients with renal impairment.
5. Sulfonamides are contraindicated if hypersensitivity exists to sulfonamides, sulfonylureas, or thiazide or loop diuretics.
6. Sulfonamides are contraindicated in infants younger than 2 months and in pregnant persons or persons who are breast-feeding or chestfeeding.
7. Sulfonamides can potentiate the effects of warfarin sodium, phenytoin, and orally administered hypoglycemics. (When combined with sulfonamides, hypoglycemics may require a reduction in dosage.)
8. Instruct the client to take the medication on an empty stomach with a full glass of water.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 56.4 Urinary Tract Analgesics

- Pentosan polysulfate sodium
- Phenazopyridine

9. Instruct the client to complete the entire course of the prescribed medication.
10. Instruct the client to avoid prolonged exposure to sunlight, wear protective clothing, and apply a sunscreen to exposed skin.
11. Adults should maintain a daily urine output of at least 1200 mL by consuming 8 to 10 glasses of water each day to minimize the risk of renal damage from the medication.
12. Inform the client that some combination medications of sulfonamides can cause the urine to turn dark brown or red.
13. The sulfonamide combination of trimethoprim-sulfamethoxazole is more effective than either medication alone, because it inhibits the sequential steps in bacterial folic acid synthesis.
14. Trimethoprim-sulfamethoxazole is used cautiously with clients experiencing impaired kidney function, folate deficiency, severe allergy, or bronchial asthma.
15. An intravenous (IV) dose of trimethoprim-sulfamethoxazole is administered over 60 to 90 minutes and is not mixed with other medications.

Sulfonamides need to be withheld if a rash is noted. Inform the client to contact the PHCP if a rash appears.

IV. Urinary Tract Analgesics (Box 56.4)

A. Description: A urinary tract analgesic is administered with an antibiotic because the analgesic treats only pain, not the infection.

B. Side and adverse effects
1. Nausea
2. Headache
3. Vertigo

C. Nursing considerations
1. Instruct the client that the urine will turn red or orange and could stain clothing; tears and contact lenses will also become red- or orange-tinged.
2. A urinary tract analgesic is contraindicated in clients with renal or hepatic disease.
3. The medication interferes with accurate urine testing for glucose and ketones.

V. Anticholinergics/Antispasmodics (Box 56.5)

A. Description: Used for overactive bladder (urge incontinence)

BOX 56.5 Anticholinergics/Antispasmodics

- Darifenacin
- Dicyclomine
- Flavoxate
- Fesoterodine
- Mirabegron
- Oxybutynin chloride
- Propantheline
- Solifenacin
- Tolterodine
- Trospium

B. Side and adverse effects
1. Anorexia, nausea, vomiting, and dry mouth
2. Blurred vision
3. Confusion in older clients
4. Constipation
5. Decreased sweating
6. Dizziness
7. Drowsiness
8. Dry eyes
9. Gastric distress
10. Headache
11. Tachycardia
12. Urinary retention

C. Nursing considerations
1. Extended-release capsules should not be split, chewed, or crushed.
2. Tolterodine should be used cautiously in clients with narrow-angle glaucoma.
3. Do not administer oxybutynin to clients with known hypersensitivity, gastrointestinal or genitourinary obstruction, glaucoma, severe colitis, or myasthenia gravis.
4. Do not administer propantheline to clients with narrow-angle glaucoma, obstructive uropathy, gastrointestinal disease, or ulcerative colitis.
5. Instruct the client to avoid hazardous activities because of the effects of dizziness and drowsiness.
6. Monitor intake and output.
7. Provide gum or hard candy for dry mouth.
8. Monitor for signs of toxicity (CNS stimulation) such as hypotension or hypertension, confusion, tachycardia, flushed or red face, signs of respiratory depression, nervousness, restlessness, hallucinations, and irritability.

Antispasmodic medications used to treat overactive bladder (urge incontinence) should not be used by clients diagnosed with open-angle glaucoma. These medications will block the flow of intraocular fluid and raise the intraocular pressure. This may cause permanent damage to the optic nerve.

VI. Cholinergics

A. Description: Bethanechol chloride is a cholinergic used to increase bladder tone and function and to treat nonobstructive urinary retention and neurogenic bladder.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

B. Side and adverse effects
1. Headache
2. Hypotension
3. Flushing and sweating
4. Increased salivation
5. Nausea and vomiting
6. Abdominal cramps
7. Diarrhea
8. Urinary urgency
9. Bronchoconstriction
10. Transient complete heart block

C. Nursing considerations
1. Administer on an empty stomach, 1 hour before or 2 hours after meals to lessen nausea and vomiting.
2. Never administer by the intramuscular or IV route.
3. Monitor intake and output.
4. Monitor for increased bladder tone and function.
5. Monitor for cholinergic overdose (excessive salivation, sweating, involuntary urination and defecation, bradycardia, and severe hypotension).
6. Have atropine sulfate (antidote for cholinergic overdose) readily available for IV or subcutaneous administration.

⚠ A cholinergic such as bethanechol chloride is not given to a client who has a urinary stricture or obstruction.

VII. Medications for Preventing Organ Rejection (Box 56.6)

A. Medications include immunosuppressants, corticosteroids, cytotoxic medications, and antibodies.

B. Some medications may be used in combination to produce different actions on the immune system; combination therapy also allows for administration of the medications in lower doses, reducing the possibility of adverse effects.

C. Cyclosporine
1. Cyclosporine inhibits calcineurin and acts on T lymphocytes to suppress the production of interleukin-2, interferon-γ, and other cytokines.
2. Cyclosporine may be used to prevent rejection of allogeneic kidney, liver, and heart transplants.
3. Prednisone may be administered concurrently.
4. Oral administration of cyclosporine is preferred; IV administration is reserved for clients who cannot take the medication orally.
5. Blood levels of the medication need to be measured regularly because of its nephrotoxic effects.
6. The most common adverse effects are nephrotoxicity, infection, hypertension, tremor, and hirsutism.
7. Assure the client that hirsutism is reversible; instruct on depilatory (hair removal) methods.

BOX 56.6 Medications for Preventing Organ Rejection

Immunosuppressants
- Cyclosporine
- Sirolimus
- Tacrolimus
- Everolimus

Glucocorticoid
- Prednisone

Cytotoxic Medications
- Azathioprine
- Mercaptopurine
- Mycophenolate mofetil

Antibodies
- Antithymocyte globulin, equine
- Basiliximab

8. Other adverse effects include neurotoxicity, gastrointestinal effects, hyperkalemia, and hyperglycemia.
9. The risk of infection and lymphomas is increased with the use of cyclosporine.
10. Cyclosporine is contraindicated in the presence of hypersensitivity, pregnancy, breast-feeding or chest-feeding, recent inoculation with live virus vaccines, or recent contact with an active infection such as chicken pox or herpes zoster.
11. Cyclosporine is embryotoxic, and persons of childbearing age should use a mechanical form of contraception and avoid oral contraceptives.
12. The client should be informed about the possibility of renal damage and liver damage. The client should also be informed of the need for periodic liver function tests and the determination of coagulation factors and blood urea nitrogen, serum creatinine, serum potassium, and blood glucose levels.
13. The client should be instructed to monitor for early signs of infection and to report these signs immediately.
14. Available in a pill form; if the client is unable to swallow the pill, instruct the client to follow the medication administration instructions exactly; dispense the oral liquid medication into a glass container using a specially calibrated pipette, mix well, and drink immediately; rinse the glass container with diluent and drink it to ensure ingestion of the complete dose; dry the outside of the pipette and return to its cover for storage.
15. To promote palatability, instruct the client to mix the liquid medication with milk, chocolate milk, or orange juice just before administration.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

16. Consuming grapefruit juice is prohibited because it raises cyclosporine levels and increases the risk of toxicity.
17. Ketoconazole, erythromycin, and amphotericin B can elevate cyclosporine levels.
18. Phenytoin, phenobarbital, rifampin, and trimethoprim-sulfamethoxazole can decrease cyclosporine levels.
19. Renal damage can be intensified by the concurrent use of other nephrotoxic medications.

D. Sirolimus

1. Sirolimus is used for the prevention of renal transplant rejection by inhibiting the response of helper T lymphocytes and B lymphocytes to cytokinesis.
2. It may be used with cyclosporine or tacrolimus and corticosteroids.
3. Increases the risk of infection, increases the risk of renal injury, increases the risk of lymphocele (a complication of renal transplant surgery), and raises cholesterol and triglyceride levels
4. Side and adverse effects include rash, acne, anemia, thrombocytopenia, joint pain, diarrhea, and hypokalemia.

E. Tacrolimus

1. Tacrolimus inhibits calcineurin and thereby prevents T cells from producing interleukin-2, interferon-γ, and other cytokines.
2. Tacrolimus is more effective than cyclosporine but is more toxic.
3. Adverse effects are similar to those of cyclosporine and include nephrotoxicity, infection, hypertension, tremor, hirsutism, neurotoxicity, gastrointestinal effects, hyperkalemia, and hyperglycemia.
4. Tacrolimus should be used cautiously in immunosuppressed clients and in those with renal, hepatic, or pancreatic impairment.
5. Tacrolimus is contraindicated for clients hypersensitive to cyclosporine.
6. Monitor blood glucose levels and administer prescribed insulin or oral hypoglycemics.

F. Everolimus

1. Binds to mechanistic target of rapamycin (mTOR), thereby suppressing T-cell activation and proliferation
2. Everolimus can be used with cyclosporine to prevent renal rejection; take every 12 hours with cyclosporine.
3. Common adverse effects with everolimus include headache, insomnia, paresthesias, hypertension, and peripheral edema.
4. Do not take everolimus with grapefruit juice.
5. Teach clients to avoid crowds and individuals who have received live vaccines due to the high risk of infection.

G. Prednisone

1. Prednisone is a glucocorticoid that inhibits accumulation of inflammatory cells at inflammation sites.
2. Hyperglycemia and hypokalemia can occur with prednisone use; monitor glucose and serum potassium levels.
3. See Chapter 48 for additional information about prednisone.

H. Azathioprine

1. Azathioprine suppresses cell-mediated and humoral immune responses by inhibiting the proliferation of B and T lymphocytes.
2. Can cause neutropenia and thrombocytopenia from bone marrow suppression
3. Contraindicated in pregnancy; associated with an increased incidence of neoplasms
4. Monitor hematocrit, white blood cell count, platelet count, liver enzyme levels, and coagulation factors.

I. Mycophenolate mofetil

1. Mycophenolate mofetil causes selective inhibition of B- and T-lymphocyte proliferation.
2. May be used with cyclosporine or tacrolimus and glucocorticoids for prophylaxis against organ rejection
3. Adverse effects include diarrhea, severe neutropenia, vomiting, and sepsis.
4. Mycophenolate mofetil is associated with an increased risk of infection and malignancies.
5. Absorption is decreased by the use of **magnesium** and aluminum antacids and by cholestyramine.
6. It is contraindicated in pregnancy and during breast-feeding or chest-feeding.
7. Instruct the client to take the medication on an empty stomach and not to open or crush capsules.
8. Instruct the client to contact the PHCP for unusual bleeding or bruising, sore throat, mouth sores, abdominal pain, or fever.

! Persons who have undergone organ transplant, such as a kidney, must take the prescribed immunosuppressant medications at the same time each day to ensure that the immune system is sufficiently suppressed to prevent organ rejection.

J. Basiliximab

1. Basiliximab binds to interleukin-2 receptors on lymphocytes, resulting in diminished cell-mediated immune reactions.
2. Used primarily as an induction agent at the time of transplantation; may be used with other immunosuppressants to prevent acute rejection of transplanted kidneys

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Administered by the IV route; initial dose is administered within 2 hours before transplantation.
4. Side and adverse effects include headache, insomnia, dizziness, and tremors; chest pain, gastrointestinal distress, edema, shortness of breath, pain in the joints, and slow wound healing can also occur.

K. Antithymocyte globulin, equine

1. Antithymocyte globulin, equine, causes a decrease in the number and activity of thymus-derived lymphocytes and is used to suppress organ rejection following renal, liver, bone marrow, and heart transplantation.
2. It is used primarily to treat acute rejection episodes.
3. Before the first infusion, the client should undergo intradermal skin testing to determine hypersensitivity.
4. Because this product is made using equine and human blood components, it may carry a risk of transmitting infectious agents, such as viruses.
5. Monitor the platelet count and report low counts to the PHCP per agency policy.
6. Arrange for outpatient referral for repeated infusions after discharge.

VIII. Hematopoietic Growth Factors (Box 56.7)

A. Erythropoietic growth factors

1. Stimulate the production of red blood cells
2. Used to treat anemia of chronic kidney disease, chemotherapy-induced anemia, anemia caused by zidovudine, and anemia in clients requiring surgery
3. Initial effects can be seen within 1 to 2 weeks, and the hematocrit reaches normal levels in 2 to 3 months.
4. Major adverse effect is hypertension.
5. Adverse effects can also include heart failure, thrombotic effects such as stroke or myocardial infarction, and cardiac arrest.

B. Leukopoietic growth factors

1. Stimulate the production of white blood cells (leukocytes)
2. Used for clients undergoing myelosuppressive chemotherapy or bone marrow transplantation and those with severe chronic neutropenia
3. Can cause bone pain, leukocytosis, and elevation of plasma uric acid, lactate dehydrogenase, and alkaline phosphatase levels; long-term therapy has caused splenomegaly.

C. Thrombopoietic growth factor

1. Stimulates the production of platelets
2. Used for clients undergoing myelosuppressive chemotherapy to minimize thrombocytopenia and to decrease the need for platelet transfusions
3. Adverse effects include fluid retention, cardiac dysrhythmias, conjunctival infection, visual blurring, and papilledema.

BOX 56.7 Hematopoietic Growth Factors

Erythropoietic Growth Factors

- Epoetin alfa
- Darbepoetin alfa
- Peginesatide

Leukopoietic Growth Factors

- Filgrastim
- Pegfilgrastim
- Sargramostim

BOX 56.8 Medications to Treat Benign Prostatic Hyperplasia

Alpha blockers

- Alfuzosin
- Doxazosin
- Tamsulosin
- Silodosin
- Terazosin

5a-alpha reductase inhibitors

- Finasteride
- Dutasteride

IX. Medications for Benign Prostatic Hyperplasia (Box 56.8)

A. Alpha blockers

1. Relax bladder neck muscles and muscle fibers in the prostate, allowing urine to pass more easily
2. Adverse effects include dizziness and retrograde ejaculation.

B. 5a-alpha reductase inhibitors

1. Shrinks the prostate by preventing hormonal changes that result in growth of the prostate
2. May take up to 6 months to be effective
3. Adverse effects include retrograde ejaculation.

PRACTICE QUESTIONS

1. A client who has a cold is seen in the emergency department with an inability to void. Because the client has a history of benign prostatic hyperplasia, the nurse determines that the client would be questioned about the use of which medication?
   1. Diuretics
   2. Antibiotics
   3. Antilipemics
   4. Decongestants

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Nitrofurantoin is prescribed for a client with a urinary tract infection. The client contacts the nurse and reports a cough, chills, fever, and difficulty breathing. The nurse would make which interpretation about the client's complaints?
1. The client may have contracted the flu.
2. The client is experiencing anaphylaxis.
3. The client is experiencing expected effects of the medication.
4. The client is experiencing a pulmonary reaction requiring cessation of the medication.

3. The nurse is providing discharge instructions to a client receiving trimethoprim-sulfamethoxazole. Which instruction would be included in the list?
1. Advise that sunscreen is not needed.
2. Drink 8 to 10 glasses of water per day.
3. Decrease the dosage when symptoms are improving to prevent an allergic response.
4. If the urine turns dark brown, call the primary health care provider (PHCP) immediately.

4. Trimethoprim-sulfamethoxazole is prescribed for a client. The nurse would instruct the client to report which symptom if it develops during the course of this medication therapy?
1. Nausea
2. Diarrhea
3. Headache
4. Sore throat

5. Phenazopyridine is prescribed for a client with a urinary tract infection. The nurse evaluates that the medication is **effective** based on which observation?
1. Urine is clear amber.
2. Urination is not painful.
3. Urge incontinence is not present.
4. A reddish-orange discoloration of the urine is present.

6. Bethanechol chloride is prescribed for a client with urinary retention. The nurse would contact the prescriber if which disorder, a contraindication to the medication, was documented in the client's record?
1. Gastric atony
2. Urinary strictures
3. Neurogenic atony
4. Gastroesophageal reflux

7. The nurse, who is administering bethanechol chloride, is monitoring for cholinergic overdose associated with the medication. The nurse would check the client for which sign of overdose?
1. Dry skin
2. Dry mouth
3. Bradycardia
4. Signs of dehydration

8. Oxybutynin chloride is prescribed for a client with urge incontinence. Which sign would indicate a possible toxic effect related to this medication?
1. Pallor
2. Drowsiness
3. Bradycardia
4. Restlessness

9. Following kidney transplantation, cyclosporine is prescribed for a client. Which laboratory result would indicate an adverse effect from the use of this medication?
1. Hemoglobin level of 14.0 g/dL (140 mmol/L)
2. Creatinine level of 0.6 mg/dL (53 mcmol/L)
3. Blood urea nitrogen level of 25 mg/dL (8.8 mmol/L)
4. Fasting blood glucose level of 99 mg/dL (5.5 mmol/L)

10. The nurse is providing dietary instructions to a client who has been prescribed cyclosporine. Which food item would the nurse instruct the client to exclude from the diet?
1. Red meats
2. Orange juice
3. Grapefruit juice
4. Green, leafy vegetables

11. Tacrolimus is prescribed for a client who underwent a kidney transplant. Which instruction would the nurse include when teaching the client about this medication?
1. Eat at frequent intervals to avoid hypoglycemia.
2. Take the medication with a full glass of grapefruit juice.
3. Change positions carefully due to risk of orthostatic hypotension.
4. Take the oral medication every 12 hours at the same times every day.

12. The nurse is reviewing the laboratory results for a client receiving tacrolimus. Which laboratory result would indicate to the nurse that the client is experiencing an adverse effect of the medication?
1. Potassium level of 3.8 mEq/L (3.8 mmol/L)
2. Platelet count of 300,000 mm^3 (300×10^9/L)
3. Fasting blood glucose of 200 mg/dL (11.1 mmol/L)
4. White blood cell count of 6000 mm^3 (6.0×10^9/L)

13. The nurse receives a call from a client concerned about eliminating brown-colored urine after taking nitrofurantoin for a urinary tract infection. The nurse would make which appropriate response?
1. "Continue taking the medication; the brown urine occurs and is not harmful."
2. "Take magnesium hydroxide with your medication to lighten the urine color."

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. "Discontinue taking the medication, and make an appointment for a urine culture."
4. "Decrease your medication to half the dose, because your urine is too concentrated."

14. A client with chronic kidney disease is receiving epoetin alfa. Which laboratory result would indicate a therapeutic effect of the medication?
1. Hematocrit of 33% (0.33)
2. Platelet count of 400,000 mm^3 (400×10^9/L)
3. White blood cell count of 6000 mm^3 (6.0×10^9/L)
4. Blood urea nitrogen level of 15 mg/dL (5.4 mmol/L)

15. A client with a urinary tract infection is receiving ciprofloxacin by the intravenous (IV) route. The nurse appropriately administers the medication by performing which action?
1. Infusing slowly over 60 minutes
2. Infusing in a light-protective bag
3. Infusing only through a central line
4. Infusing rapidly as a direct IV push medication

ANSWERS

1. *Answer:* 4
Rationale: In the client with benign prostatic hyperplasia, episodes of urinary retention can be triggered by certain medications, such as decongestants, anticholinergics, and antidepressants. These medications lessen the voluntary ability to contract the bladder. The client would be questioned about the use of these medications and if experiencing urinary retention. Diuretics increase urine output. Antibiotics and antilipemics do not affect ability to urinate.
Test-Taking Strategy: Focus on the **subject,** medications that could exacerbate or contribute to urinary retention in the client with benign prostatic hyperplasia. Recalling that medications that contain anticholinergics may cause urinary retention will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p.1261.

2. *Answer:* 4
Rationale: Nitrofurantoin can induce two kinds of pulmonary reactions: acute and subacute. Acute reactions, which are most common, manifest with dyspnea, chest pain, chills, fever, cough, and alveolar infiltrates. These symptoms resolve 2 to 4 days after discontinuing the medication. Acute pulmonary responses are thought to be hypersensitivity reactions. Subacute reactions are rare and occur during prolonged treatment. Symptoms (e.g., dyspnea, cough, malaise) usually regress over weeks to months following nitrofurantoin withdrawal. However, in some clients, permanent lung damage may occur. The remaining options are incorrect interpretations.
Test-Taking Strategy: Focus on the **subject,** interpreting the client's complaints, and the **data in the question.** Note the relationship of the information in the question and the words *pulmonary reaction* in the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 921-922.

3. *Answer:* 2
Rationale: Each dose of trimethoprim-sulfamethoxazole should be administered with a full glass of water, and the client would maintain a high fluid intake to avoid crystalluria. The medication is more soluble in alkaline urine. The client would not be instructed to taper or discontinue the dose. Clients would be advised to use sunscreen since the skin becomes sensitive to the sun. Some forms of trimethoprim-sulfamethoxazole cause urine to turn dark brown or red. This does not indicate the need to notify the PHCP.
Test-Taking Strategy: Focus on the **subject,** client instructions for trimethoprim-sulfamethoxazole. Recalling that this medication is used to treat urinary tract infections will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 1342-1343.

4. *Answer:* 4
Rationale: Clients taking trimethoprim-sulfamethoxazole need to be informed about early signs and symptoms of blood disorders that can occur from this medication. These include sore throat, fever, and pallor, and the client needs to be instructed to notify the primary health care provider (PHCP) if these occur. The other options do not require PHCP notification.
Test-Taking Strategy: Focus on the **subject,** the symptoms to report. Knowledge that this medication can cause blood dyscrasias will direct you to the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 1171-1172.

5. *Answer:* 2
Rationale: Phenazopyridine is a urinary analgesic. It is effective when it eliminates pain and burning with urination. It does not eliminate the bacteria causing the infection, so it would not make the urine clear amber. It does not treat urge incontinence. It will cause the client to have reddish-orange discoloration of urine, but this is a side effect of the medication, not the desired effect.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Note the **strategic word,** *effective*. Focus on the **subject,** effectiveness of phenazopyridine. Recalling the classification of this medication and that it is a urinary analgesic will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 1342.

6. *Answer:* 2
Rationale: Bethanechol chloride can be hazardous to clients with urinary tract obstruction or weakness of the bladder wall. The medication has the ability to contract the bladder and thereby increase pressure within the urinary tract. Elevation of pressure within the urinary tract could damage or rupture the bladder in clients with these conditions.
Test-Taking Strategy: Focus on the **subject,** a contraindication for the use of the medication. Noting that the medication is used for urinary retention may assist in directing you to the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 157-158.

7. *Answer:* 3
Rationale: Cholinergic overdose of bethanechol chloride produces manifestations of excessive muscarinic stimulation such as salivation, sweating, involuntary urination and defecation, bradycardia, and severe hypotension. Remember that the sympathetic nervous system speeds the heart rate and the cholinergic (parasympathetic) nervous system slows the heart rate. Treatment includes supportive measures and the administration of atropine sulfate (anticholinergic) subcutaneously or intravenously.
Test-Taking Strategy: Focus on the **subject,** signs of cholinergic overdose. Noting that options 1, 2, and 4 are **comparable or alike** will assist in eliminating these options.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 157-158.

8. *Answer:* 4
Rationale: Toxicity (overdosage) of oxybutynin produces central nervous system excitation, such as nervousness, restlessness, hallucinations, and irritability. Other signs of toxicity include hypotension or hypertension, confusion, tachycardia, flushed or red face, and signs of respiratory depression. Drowsiness is a frequent side effect of the medication but does not indicate overdosage.
Test-Taking Strategy: Focus on the **subject,** signs of toxicity (overdosage) of oxybutynin. Remember that restlessness is a sign of toxicity.
Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. pp. 879-880.

9. *Answer:* 3
Rationale: Cyclosporine is an immunosuppressant. Nephrotoxicity can occur from the use of cyclosporine. Nephrotoxicity is evaluated by monitoring for elevated blood urea nitrogen and serum creatinine levels. The normal blood urea nitrogen level is 10 to 20 mg/dL (3.6 to 7.1 mmol/L). The normal creatinine level ranges from 0.5 to 1.2 mg/dL (44 to 106 mcmol/L). Cyclosporine can lower complete blood cell count levels. A normal hemoglobin ranges from12 to 18 g/dL (120 to 180 mmol/L). A normal hemoglobin is not an adverse effect. The normal fasting glucose is 70 to 99 mg/dL (3.9–5.5 mmol/L).
Test-Taking Strategy: Focus on the **subject,** the adverse effects of cyclosporine. Recall that cyclosporine can be nephrotoxic. The correct option is the only one that indicates an increased level of a renal function test. Also, recalling the normal laboratory reference levels will direct you to the correct option, the only abnormal level.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 335.

10. *Answer:* 3
Rationale: A compound present in grapefruit juice inhibits metabolism of cyclosporine through the cytochrome P450 system. As a result, consumption of grapefruit juice can raise cyclosporine levels by 50% to 100%, thereby greatly increasing the risk of toxicity. Red meats, orange juice, and green, leafy vegetables do not interact with the cytochrome P450 system.
Test-Taking Strategy: Focus on the **subject,** the item to exclude from the diet. Recall that grapefruit juice is contraindicated with many medications. Use of general pharmacology guidelines will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 206-207.

11. *Answer:* 4
Rationale: Tacrolimus is a potent immunosuppressant used to prevent organ rejection in transplant clients. It is important that the medication be taken at 12-hour intervals to maintain a stable blood level to prevent organ rejection. Adverse effects include hyperglycemia and hypertension, so the client does not eat frequently to avoid hypoglycemia or use precautions to avoid orthostatic hypotension. Tacrolimus is metabolized through the cytochrome P450 system, so grapefruit juice is not allowed.
Test-Taking Strategy: Focus on the **subject,** teaching a transplant client regarding tacrolimus. Focus on the goal of avoiding organ rejection by maintaining a stable level of tacrolimus in the blood by taking the medication at regular intervals every day.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 1179.

12. *Answer:* 3
Rationale: A fasting blood glucose level of 200 mg/dL (11.1 mmol/L) is significantly elevated above the normal range of 70 to 99 mg/dL (3.9–5.5 mmol/L) and suggests an adverse effect. Recall that fasting blood glucose levels are sometimes based on primary health care provider preference. Other adverse effects include neurotoxicity evidenced by headache, tremor, and insomnia; gastrointestinal effects such as diarrhea, nausea, and vomiting; hypertension; and hyperkalemia. The remaining options identify normal reference levels. The normal potassium level is 3.5 to 5.0 mEq/L (3.5 to 5.0

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

mmol/L). The normal platelet count is 150,000 to 400,000 mm^3 (150 to 400 × 10^9/L). The normal white blood cell count is 5000 to 10,000 mm^3 (5 to 10 × 10^9/L).
Test-Taking Strategy: Focus on the **subject,** an adverse effect. Note that options 1, 2, and 4 are **comparable or alike** and represent normal values. The correct option has the only abnormal value, reflecting an elevation.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 1181.

13. *Answer:* 1
Rationale: Nitrofurantoin imparts a harmless brown color to the urine, and the medication should not be discontinued until the prescribed dose is completed. Magnesium hydroxide will not affect urine color. In addition, antacids need to be avoided because they interfere with medication effectiveness.
Test-Taking Strategy: Focus on the **subject,** brown-colored urine. Option 2 can be eliminated, because antacids need to be avoided as a result of their interference with the effectiveness of nitrofurantoin. In addition, magnesium hydroxide will not have an effect on urine color. Next, eliminate options 3 and 4, because the nurse would not tell the client to discontinue medication or alter the dose.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1027-1028; Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference* (34th ed.). St. Louis: Elsevier. pp. 921-922.

14. *Answer:* 1
Rationale: Epoetin alfa is synthetic erythropoietin, which the kidneys produce to stimulate red blood cell production in the bone marrow. It is used to treat anemia associated with chronic kidney disease. The normal hematocrit level ranges from 37% to 52% (0.37 to 0.52). Therapeutic effect is seen when the hematocrit reaches between 30% and 33% (0.30 and 0.33). The normal platelet count is 150,000 to 400,000 mm^3 (150 to 400 × 10^9/L). The normal blood urea nitrogen level is 10 to 20 mg/dL (3.6 to 7.1 mmol/L). The normal white blood cell count is 5000 to 10,000 mm^3 (5 to 10 × 10^9/L). Platelet production, white blood cell production, and blood urea nitrogen do not respond to erythropoietin.
Test-Taking Strategy: Focus on the **subject,** a therapeutic effect. Relate the name of the medication, epoetin alfa, to the potential action or effect of erythropoietin. The only laboratory test that would reflect the effect of this medication is a hematocrit of 33% (0.33), found in the correct option.
Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 484-485.

15. *Answer:* 1
Rationale: Ciprofloxacin is prescribed for treatment of mild, moderate, severe, and complicated infections of the urinary tract, lower respiratory tract, and skin and skin structure. A single dose is administered slowly over 60 minutes to minimize discomfort and vein irritation. Ciprofloxacin is not light-sensitive, may be infused through a peripheral IV access, and is not given by IV push method.
Test-Taking Strategy: Focus on the **subject,** the appropriate way to administer an IV medication ciprofloxacin. Recall that this medication has adverse effects, so IV push would not be the recommended method of administration. Eliminate option 3 because of the **closed-ended word** "only." Next, it is necessary to know that the presence of light does not affect the integrity of this medication.

UNIT XIV

Eye and Ear Problems of the Adult Client

Pyramid to Success

Pyramid Points focus on safety and nursing interventions for clients with impairment of sight or hearing and on the nursing care related to disorders such as cataracts, glaucoma, and retinal detachment. Communicating with clients who are visually or hearing impaired is also a priority. Emergency interventions for eye and ear disorders and injuries are a priority point. Pyramid Points also focus on client instructions related to medication administration, sensory perceptual alterations and safety issues, and available support systems.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Caring for the recipient of a tissue (corneal) donation
Communicating with the interprofessional health care team
Maintaining asepsis with procedures and treatments
Maintaining standard and other precautions
Preventing accidents that can occur as a result of sensory impairments
Prioritizing hypotheses based on client needs
Recognizing cues that indicate a need for initiating safety measures
Upholding client rights
Verifying that informed consent for invasive procedures is obtained

Health Promotion and Maintenance

Discussing changes that occur with the aging process
Discussing expected body image changes and self-care deficits
Generating solutions to assist the client who has a visual or hearing impairment
Implementing measures for the prevention and early detection of health problems and diseases related to the eye and the ear
Performing physical assessments of the eye and ear

Psychosocial Integrity

Assessing the client's ability to cope with feelings of isolation, fear, or anxiety regarding a possible change in vision and/or hearing status, and loss of independence
Considering the cultural, religious, and spiritual influences of the client when planning care
Discussing body image and role changes
Identifying family support systems
Informing the client about available community resources
Monitoring for sensory perceptual alterations
Using appropriate communication techniques for impaired vision and hearing

Physiological Integrity

Analyzing cues that indicate complications related to procedures and treatments
Evaluating outcomes related to expected responses to therapy
Providing care for assistive devices such as eyeglasses, contact lenses, and hearing aids
Providing home care instructions following procedures related to the eye and ear
Providing instructions regarding activity limitations or postoperative activities
Providing instructions regarding the administration of eye and ear medications
Taking action in medical emergencies
Teaching regarding the importance of compliance with the prescribed therapy

CHAPTER 57

Eye and Ear Problems

Contributor: Necole Leland, DNP, RN, PNP, CPN

PRIORITY CONCEPTS Safety, Sensory Perception

I. Anatomy and Physiology of the Eye

A. The eye
- **1.** The eye is 1 inch (2.5 cm) in diameter and is located in the anterior portion of the orbit.
- **2.** The orbit is the bony structure of the skull that surrounds the eye and offers protection to the eye.

B. Layers of the eye
- **1.** External layer
  - **a.** The fibrous coat that supports the eye
  - **b.** Contains the cornea, the dense transparent outer layer
  - **c.** Contains the sclera, the fibrous "white of the eye"
- **2.** Middle layer
  - **a.** Called the *uveal tract*
  - **b.** Consists of the choroid, ciliary body, and iris
  - **c.** The choroid is the dark brown membrane located between the sclera and the retina that has dark pigmentation to prevent light from reflecting internally.
  - **d.** The choroid lines most of the sclera and is attached to the retina but can detach easily from the sclera.
  - **e.** The choroid contains many blood vessels and supplies nutrients to the retina.
  - **f.** The ciliary body connects the choroid with the iris and secretes aqueous humor that helps give the eye its shape; the muscles of the ciliary body control the thickness of the lens.
  - **g.** The iris is the colored portion of the eye, located in front of the lens, and it has a central circular opening called the *pupil*. The pupil controls the amount of light (darkness produces dilation and light produces constriction) admitted into the retina.
- **3.** Internal layer
  - **a.** Consists of the retina, a thin, delicate structure in which the fibers of the optic nerve are distributed.
  - **b.** The retina is bordered externally by the choroid and sclera and internally by the vitreous.
  - **c.** The retina is the visual receptive layer of the eye in which light waves are changed into nerve impulses; it contains blood vessels and photoreceptors called *rods* and *cones*.

C. Vitreous body
- **1.** Contains a gelatinous substance that occupies the vitreous chamber, the space between the lens and the retina
- **2.** The vitreous body transmits light and gives shape to the posterior eye.

D. Vitreous
- **1.** Gel-like substance that maintains the shape of the eye
- **2.** Provides additional physical support to the retina

E. Rods and cones
- **1.** Rods are responsible for peripheral vision and function at reduced levels of illumination.
- **2.** Cones function at bright levels of illumination and are responsible for color vision and central vision.

F. Optic disc
- **1.** It is a creamy pink to white depressed area in the retina.
- **2.** The optic nerve enters and exits the eyeball at this area.
- **3.** This area is called the *blind spot* because it contains only nerve fibers, lacks photoreceptor cells, and is insensitive to light.

G. Macula lutea
- **1.** Small, oval, yellowish-pink area located laterally and temporally to the optic disc

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. The central depressed part of the macula is the fovea centralis, the area of sharpest and keenest vision, where most acute vision occurs.
3. Its functions include central vision, night and color vision, and motion detection.

H. Aqueous humor
1. A clear, watery fluid that fills the anterior and posterior chambers of the eye
2. It is produced by the ciliary processes, and the fluid drains into the canal of Schlemm.
3. The anterior chamber lies between the cornea and the iris.
4. The posterior chamber lies between the iris and the lens.

I. Canal of Schlemm: Passageway that extends completely around the eye; it permits fluid to drain out of the eye into the systemic circulation so that a constant intraocular pressure (IOP) is maintained.

J. Lens
1. Transparent convex structure behind the iris and in front of the vitreous body
2. The lens bends rays of light so that the light falls on the retina.
3. The curve of the lens changes to focus on near or distant objects.

K. Conjunctivae: Thin, transparent mucous membranes of the eye that line the posterior surface of each eyelid, located over the sclera

L. Lacrimal gland: Produces tears that are drained through the punctum into the lacrimal duct and sac

M. Eye muscles
1. Muscles do not work independently; each muscle works with the muscle that produces the opposite movement.
2. Rectus muscles exert their pull when the eye turns temporally.
3. Oblique muscles exert their pull when the eye turns nasally.

N. Nerves
1. Cranial nerve II: Optic nerve (sight)
2. Cranial nerve III: Oculomotor (eye movement)
3. Cranial nerve IV: Trochlear (eye movement)
4. Cranial nerve VI: Abducens (eye movement)

O. Blood vessels
1. The ophthalmic artery is the major artery supplying the structures in the eye.
2. The ophthalmic veins drain the blood from the eye.

II. Assessment of Vision (see Chapter 12)

III. Diagnostic Tests for the Eye

A. Fluorescein angiography
1. Description
   a. A detailed imaging and recording of ocular circulation by a series of photographs taken after the administration of a dye
   b. Used to assess problems with retinal circulation, such as those that occur in diabetic retinopathy, retinal bleeding, and **macular degeneration**, or to rule out intraocular tumors
2. Preprocedure interventions
   a. Assess the client for allergies and previous reactions to dyes.
   b. An **informed consent** is necessary.
   c. A **mydriatic** medication, which causes pupil dilation, is instilled into the eye 1 hour before the test.
   d. The dye is injected into a vein of the client's arm.
   e. Inform the client that the dye may cause the skin to appear yellow for several hours after the test and that it is eliminated gradually through the urine. Urine may be bright green or orange for up to 2 days following the procedure.
   f. The client may experience nausea, vomiting, sneezing, paresthesia of the tongue, or pain at the injection site.
   g. If hives appear, antihistamines such as diphenhydramine are administered as prescribed.
3. Postprocedure interventions
   a. Encourage rest.
   b. Encourage fluid intake to assist in eliminating the dye.
   c. Remind the client that the yellow skin appearance will disappear.
   d. Inform the client that the urine will appear bright green or orange until the dye is excreted.
   e. Advise the client to avoid direct sunlight for a few hours after the test and to wear sunglasses, if staying indoors is not possible.
   f. Inform the client that the photophobia will continue until pupil size returns to normal.

B. Computed tomography (CT)
1. Description
   a. The test is performed to examine the eye, bony structures around the eye, and extraocular muscles.
   b. Contrast material may be used unless eye trauma is suspected.
2. Interventions
   a. No special client preparation or follow-up care is required.
   b. Instruct the client they will be positioned in a confined space and will need to keep the head still during the procedure.
   c. Ask about and document allergies and/or previous exposure to contrast.

C. Slit lamp
1. Description
   a. Allows examination of the anterior ocular structures under microscopic magnification

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

b. The client leans on a chin rest to stabilize the head while a narrowed beam of light is aimed so that it illuminates only a narrow segment of the eye.

2. Interventions: Advise the client about the brightness of the light and the need to look forward at a point over the examiner's ear.

D. Corneal staining

1. Description

a. A topical dye is instilled into the conjunctival sac to outline irregularities of the corneal surface that are not easily visible.

b. The eye is viewed through a blue filter, and a bright green color indicates areas of a nonintact corneal epithelium.

2. Interventions

a. If the client wears contact lenses, the lenses must be removed.

b. The client is instructed to blink after the dye has been applied to distribute the dye evenly across the cornea.

E. Tonometry

1. Description: The test is used primarily to assess for an increase in IOP and potential **glaucoma.**

2. Noncontact tonometry

a. No direct contact with the client's cornea is needed, and no topical eye anesthetic is needed.

b. A puff of air is directed at the cornea to indent the cornea, which can be unpleasant and may startle the client.

c. It is a less accurate method of measurement compared with contact tonometry.

3. Contact tonometry

a. Requires a topical anesthetic

b. A flattened cone is brought into contact with the cornea, and the amount of pressure needed to flatten the cornea is measured.

c. The client must be instructed to avoid rubbing the eye following the examination if the eye has been anesthetized because of the potential for scratching the cornea.

Normal IOP is 10 to 21 mm Hg; IOP varies throughout the day and is normally higher in the morning (always document the time of IOP measurement).

F. Ultrasound: The procedure is similar to ultrasound procedures done in other parts of the body and is done to detect lesions or tumors in the eye.

G. Magnetic resonance imaging (MRI): Similar to an MRI done in other parts of the body; refer to Chapter 59 for additional information on MRI.

BOX 57.1 Risk Factors for Eye Problems

- Aging process
- Congenital
- Diabetes mellitus
- Hereditary
- Medications
- Trauma

IV. Problems of the Eye

A. Risk factors related to eye problems (Box 57.1)

B. Refractive errors

1. Description

a. Refraction is the bending of light rays; any problem associated with eye length or refraction can lead to refractive errors.

b. **Myopia** (nearsightedness): Refractive ability of the eye is too strong for the eye length; images are bent and fall in front of, not on, the retina.

c. **Hyperopia** (farsightedness): Refractive ability of the eye is too weak; images are focused behind the retina.

d. Presbyopia: Loss of lens elasticity because of aging; less able to focus the eye for close work, and images fall behind the retina.

e. **Astigmatism:** Occurs because of the irregular curvature of the cornea; image focuses at two different points on the retina.

2. Assessment

a. Refractive errors are diagnosed through a process called *refraction.*

b. The client views an eye chart while various lenses of different strengths are systematically placed in front of the eye and is asked whether the lenses sharpen or worsen the vision.

3. Nonsurgical interventions: Eyeglasses or contact lenses

4. Surgical interventions

a. Radial keratotomy: Incisions are made through the peripheral cornea to flatten the cornea, which allows the image to be focused closer to the retina; used to treat myopia.

b. Photorefractive keratotomy: A laser beam is used to remove small portions of the corneal surface to reshape the cornea to focus an image properly on the retina; used to treat myopia and astigmatism.

c. Laser-assisted in-situ keratomileusis (LASIK): The superficial layers of the cornea are lifted as a flap, a laser reshapes the deeper corneal layers, and then the corneal flap is replaced; used to treat hyperopia, myopia, and astigmatism.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

d. Corneal ring: The shape of the cornea is changed by placing a flexible ring in the outer edges of the cornea; used to treat myopia.

C. Legal blindness

1. Description: In the client who is **legally blind**, the best visual acuity with corrective lenses in the better eye is 20/200 or less, or the visual field is no greater than 20 degrees in its widest diameter in the better eye.

2. Interventions

a. When speaking to the client who has limited sight or is blind, the nurse should use a normal tone of voice.

b. Alert the client when approaching.

c. Orient the client to the environment.

d. Use a focal point and provide further orientation to the environment from that focal point; ensure that the client has a clear pathway.

e. Allow the client to touch objects in the room.

f. Use the clock placement of foods on the meal tray to orient the client.

g. Promote independence as much as is possible.

h. Provide radios, televisions, and clocks that give the time orally, or provide a Braille watch.

i. When ambulating, allow the client to grasp the nurse's arm at the elbow; the nurse keeps their arm close to the body so that the client can detect the direction of movement.

j. Instruct the client to remain one step behind the nurse when ambulating.

k. Instruct the client in the use of the cane for the blind, which is differentiated from other canes by its straight shape and white color with red tip.

l. Instruct the client that the cane is held in the dominant hand several inches (centimeters) off the floor.

m. Instruct the client that the cane sweeps the ground where the client's foot will be placed next to determine the presence of obstacles.

D. Cataracts (Fig. 57.1)

1. Description

a. A cataract is an opacity of the lens that distorts the image projected onto the retina and that can progress to blindness.

b. Causes include the aging process (senile cataracts), heredity (congenital cataracts), and injury (traumatic cataracts); cataracts also can result from another eye disease (secondary cataracts).

c. Causes of secondary cataracts include **diabetes mellitus**, maternal rubella, severe myopia, ultraviolet light exposure, and medications such as corticosteroids.

FIG. 57.1 The cloudy appearance of a lens affected by cataract. (From Patton, Thibodeau, 2010.)

d. Intervention is indicated when visual acuity has been reduced to a level that the client finds unacceptable or that adversely affects the client's lifestyle.

2. Assessment

a. Blurred vision and decreased color perception are early signs.

b. Diplopia, reduced visual acuity, absence of the red reflex, and the presence of a white pupil are late signs. Pain or eye redness is associated with age-related cataract formation.

c. Loss of vision is gradual.

3. Interventions

a. Surgical removal of the lens, one eye at a time, is performed.

b. With extracapsular extraction, the lens is lifted out without removing the lens capsule; the procedure may be performed by phacoemulsification, in which the lens is broken up by ultrasonic vibrations and extracted.

c. With intracapsular extraction, the lens and capsule are removed completely.

d. A partial iridectomy may be performed with the lens extraction to prevent acute secondary glaucoma.

e. A lens implantation may be performed at the time of the surgical procedure.

4. Preoperative interventions

a. Instruct the client regarding postoperative measures, such as the importance of handwashing, and measures to prevent or decrease IOP (e.g., to avoid bending over, coughing, straining, and rubbing the eye).

b. Stress to the client that care after surgery requires the instillation of various types of eye drops several times a day for 2 to 4 weeks.

c. Administer eye medications preoperatively, including mydriatics and cycloplegics as prescribed.

5. Postoperative interventions

a. Elevate the head of the bed 30 to 45 degrees.

b. Turn the client to the back or nonoperative side.

c. Maintain an eye patch as prescribed; orient the client to the environment.

d. Position the client's personal belongings to the nonoperative side.

e. Use side rails for safety (per agency guidelines).

f. Assist with ambulation.

6. Client education (Box 57.2)

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 57.2 Client Education Following Cataract Surgery

- Avoid eye straining.
- Avoid rubbing or placing pressure on the eyes.
- Avoid rapid movements, straining, sneezing, coughing, bending, vomiting, or lifting objects heavier than 5 lb (2.25 kg) or as prescribed.
- Take measures to prevent constipation.
- Follow instructions for dressing changes and prescribed eye drops and medications.
- Wipe excess drainage or tearing with a sterile wet cotton ball from the inner to the outer canthus.
- Use an eye shield at bedtime.
- If lens implantation is not performed, accommodation is affected and glasses must be worn at all times.
- Cataract glasses act as magnifying glasses and replace central vision only, and objects will appear closer; therefore, the client needs to accommodate, judge distance, and climb stairs carefully.
- Contact lenses provide sharp visual acuity, but dexterity is needed to insert them.
- Eye itching and mild discomfort are normal for a few days after the procedure.
- Contact the health care provider about any decrease in vision, severe eye pain, increase in redness, or increase in eye discharge.

E. Glaucoma

1. Description

a. A group of ocular diseases resulting in increased IOP

b. IOP is the fluid (aqueous humor) pressure within the eye (normal IOP is 10 to 21 mm Hg).

c. Increased IOP results from inadequate drainage of aqueous humor from the canal of Schlemm or overproduction of aqueous humor.

d. The condition damages the optic nerve and can result in blindness.

e. The gradual loss of visual fields may go unnoticed, because central vision is unaffected.

2. Types

a. Primary open-angle glaucoma (POAG) results from obstruction to outflow of aqueous humor and is the most common type.

b. Primary angle-closure glaucoma (PACG) results from blocking the outflow of aqueous humor into the trabecular meshwork; causes include lens or pupil dilation from medications or sympathetic stimulation.

3. Assessment

a. Early signs include diminished **accommodation** and increased IOP.

b. POAG: Painless, and vision changes are slow; results in "tunnel" vision

c. PACG: Blurred vision, halos around lights, and ocular erythema

Acute angle-closure glaucoma is a medical emergency that causes sudden eye pain and possible nausea and vomiting.

4. Interventions for acute angle-closure glaucoma

a. Treat acute angle-closure glaucoma as a medical emergency.

b. Administer medications as prescribed to lower IOP.

c. Prepare the client for peripheral iridectomy, which allows aqueous humor to flow from the posterior to the anterior chamber.

5. Interventions for the client with glaucoma

a. Instruct the client on the importance of medications that constrict the pupils (**miotics**), decrease the production of aqueous humor (carbonic anhydrase inhibitors), and decrease the production of aqueous humor and IOP (beta blockers).

b. Instruct the client about the need for lifelong medication use, to wear a MedicAlert bracelet, to avoid anticholinergic medications to prevent increased IOP, and to contact the primary health care provider (PHCP) before taking medications, including over-the-counter medications.

c. Instruct the client to report eye pain, halos around the eyes, and changes in vision to the PHCP.

d. Instruct the client that when maximal medical therapy has failed to halt the progression of visual field loss and optic nerve damage, surgery will be recommended.

e. Prepare the client for trabeculectomy as prescribed, which allows drainage of aqueous humor into the conjunctival spaces by the creation of an opening.

F. Retinal detachment

1. Description

a. Detachment or separation of the retina from the epithelium

b. Occurs when the layers of the retina separate because of the accumulation of fluid between them, or when both retinal layers elevate away from the choroid as a result of a tumor

c. Partial detachment becomes complete if untreated.

d. When detachment becomes complete, blindness occurs.

2. Assessment

a. Flashes of light

b. Floaters or black spots (signs of bleeding)

c. Increase in blurred vision

d. Sense of a curtain being drawn over the eye

e. Loss of a portion of the visual field; painless loss of central or peripheral vision

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Immediate interventions
   a. Provide bed rest.
   b. Cover both eyes with patches as prescribed to prevent further detachment.
   c. Speak to the client before approaching.
   d. Position the client's head as prescribed.
   e. Protect the client from injury.
   f. Avoid jerky head movements.
   g. Minimize eye stress.
   h. Prepare the client for a surgical procedure as prescribed.
4. Surgical procedures
   a. Draining fluid from the subretinal space so that the retina can return to the normal position
   b. Sealing retinal breaks by cryosurgery, a cold probe applied to the sclera, to stimulate an inflammatory response leading to adhesions
   c. Diathermy, the use of an electrode needle and heat through the sclera, to stimulate an inflammatory response
   d. Laser therapy, to stimulate an inflammatory response and seal small retinal tears before the detachment occurs
   e. Scleral buckling, to hold the choroid and retina together with a splint until scar tissue forms, closing the tear (Fig. 57.2)
   f. Insertion of gas or silicone oil to promote reattachment; these agents float against the retina to hold it in place until healing occurs.

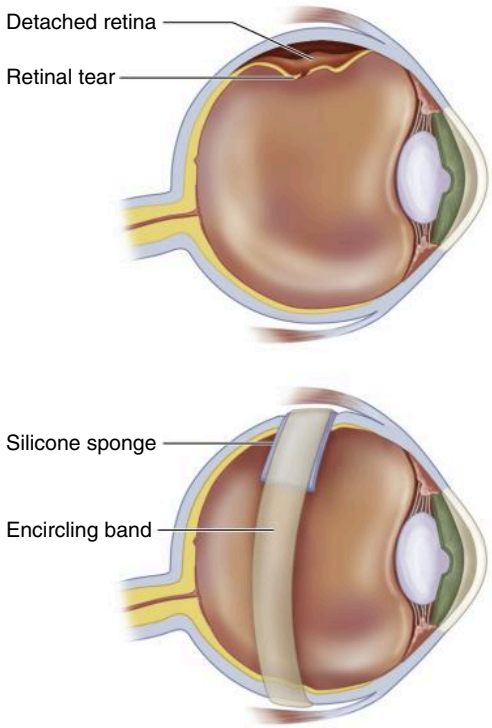

FIG. 57.2 The scleral buckling procedure for repair of retinal detachment.

5. Postoperative interventions
   a. Maintain eye patches as prescribed.
   b. Monitor for hemorrhage.
   c. Prevent nausea and vomiting and monitor for restlessness, which can cause hemorrhage.
   d. Monitor for sudden, sharp eye pain (notify the PHCP).
   e. Encourage deep breathing but avoid coughing.
   f. Provide bed rest as prescribed.
   g. Position the client as prescribed (positioning depends on the location of the detachment).
   h. Administer eye medications as prescribed.
   i. Assist the client with activities of daily living.
   j. Avoid sudden head movements or anything that increases IOP.
   k. Instruct the client to limit reading for 3 to 5 weeks.
   l. Instruct the client to avoid squinting, straining and constipation, lifting heavy objects, and bending from the waist.
   m. Instruct the client to wear dark glasses during the day and an eye patch at night.
   n. Encourage follow-up care because of the danger of recurrence or occurrence in the other eye.

G. Macular degeneration
   1. A deterioration of the macula, the area of central vision
   2. Can be atrophic (age-related or dry) or exudative (wet)
   3. Age-related: Caused by gradual blocking of retinal capillaries leading to an ischemic and necrotic macula; rod and cone photoreceptors die.
   4. Exudative: Serous detachment of pigment epithelium in the macula occurs; fluid and blood collect under the macula, resulting in scar formation and visual distortion.
   5. Interventions are aimed at maximizing the remaining vision.
   6. Assessment
      a. A decline in central vision
      b. Blurred vision and distortion
   7. Interventions
      a. Initiate strategies to assist in maximizing remaining vision and maintaining independence.
      b. Provide referrals to community organizations.
      c. Laser therapy, photodynamic therapy, or other therapies may be prescribed to seal the leaking blood vessels in or near the macula.

H. Ocular melanoma
   1. Most common malignant eye tumor in adults
   2. The tumor is usually found in the uveal tract and can spread easily because of the rich blood supply.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. Assessment
   a. Tumor can be discovered during routine examination.
   b. If the macular area is invaded, blurring of vision occurs.
   c. Increased IOP is present if the canal of Schlemm is invaded.
   d. Change of iris color is noted if the tumor invades the iris.
   e. Ultrasonography may be performed to determine tumor size and location.
4. Interventions
   a. Surgery: Enucleation
   b. Radiation may be given via a radioactive plaque that is sutured to the sclera; the radioactive plaque remains in place until the prescribed radiation dose is delivered.

I. Enucleation and exenteration
1. Description
   a. Enucleation is the removal of the entire eyeball.
   b. Exenteration is the removal of the eyeball and surrounding tissues and bone.
   c. The procedures are performed for the removal of ocular tumors.
   d. After the eye is removed, a ball implant is inserted to provide a firm base for a socket prosthesis and to facilitate the best cosmetic result.
   e. A prosthesis is fitted about 1 month after surgery.
2. Preoperative interventions
   a. Provide emotional support to the client.
   b. Encourage the client to verbalize feelings related to loss.
   c. Encourage family support in care.
3. Postoperative interventions
   a. Monitor vital signs.
   b. Check pressure patch or dressing for the presence of bright red blood or other drainage.
   c. Report changes in vital signs or the presence of bright red drainage on the pressure patch or dressing.

J. Hyphema
1. Description: Presence of blood in the anterior chamber that occurs as a result of an injury; usually resolves in 5 to 7 days.
2. Interventions
   a. Encourage rest in a semi-Fowler's position.
   b. Avoid sudden eye movements for 3 to 5 days to decrease the likelihood of bleeding.
   c. Administer cycloplegic eye drops as prescribed to relax the eye muscles and place the eye at rest.
   d. Instruct the client in the use of eye shields or eye patches as prescribed.
   e. Instruct the client to restrict reading and limit watching television.

K. Contusions
1. Description
   a. Bleeding into the soft tissue as a result of an injury.
   b. A contusion causes a black eye; the discoloration disappears in about 10 days.
   c. Pain, photophobia, edema, and diplopia may occur.
2. Interventions
   a. Place ice on the eye immediately.
   b. Instruct the client to receive a thorough eye examination.

L. Foreign bodies
1. Description: An object such as dust or dirt that enters the eye and causes irritation
2. Interventions
   a. Have the client look upward, expose the lower lid, wet a cotton-tipped applicator with sterile normal saline, gently twist the swab over the particle, and remove it.
   b. If the particle cannot be seen, have the client look downward, place a cotton applicator horizontally on the outer surface of the upper eye lid, grasp the lashes, and pull the upper lid outward and over the cotton applicator; if the particle is seen, gently twist a swab over it to remove.

M. Penetrating objects
1. Description: An eye injury in which an object penetrates the eye
2. Interventions
   a. Never remove the object, because it may be holding ocular structures in place; the object must be removed by the PHCP.
   b. Cover the eye with a cup (paper or plastic) and tape in place. Also cover the nonaffected eye (to decrease eye movements).
   c. Do not allow the client to bend over or lie flat; these positions may move the object.
   d. Do not place pressure on the eye.
   e. The client is to be seen by the PHCP immediately.
   f. X-rays and CT scans of the orbit are usually obtained.
   g. MRI is contraindicated because of the possibility of metal-containing projectile movement during the procedure.

N. Chemical burns
1. Description: An eye injury in which a caustic substance enters the eye
2. Interventions (see Clinical Judgment: Take Action box)

If a chemical splash to the eye occurs, treatment should begin immediately. Flush the eyes with water for at least 15 to 20 minutes at the scene of the injury; then the client is brought to the emergency department. If possible, obtain a sample of the chemical involved.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

CLINICAL JUDGMENT: TAKE ACTION

A client arrives in the emergency department after sustaining a chemical splash to the eye. The client tells the nurse that a bottle of nail polish remover fell off the counter when bending over to open a cabinet and that the polish remover splashed into the right eye. The client reports that the eye was immediately flushed for about 15 minutes with tap water; then the client was brought immediately to the emergency department. On arrival to the emergency department, the nurse takes the following actions:

- Quickly assesses the client and visual acuity.
- Checks the pH of the eye. Normal pH is approximately 7.11±1.5.
- Irrigates the eye continuously, until the pH is at an acceptable level.
- Contacts the ophthalmologist.
- Documents the event, actions taken, and the client's response.

O. Eye (tissue) donation
1. Donor eyes
   a. Donor eyes are obtained from cadavers.
   b. Donor eyes must be enucleated soon after death and stored in a preserving solution because of rapid endothelial cell death.
   c. Storage, handling, and coordination of donor tissue with surgeons is provided by a network of state and national eye bank associations.
2. Care to the deceased client as a potential eye donor
   a. The option of eye donation is discussed with the family.
   b. Raise the head of the bed 30 degrees.
   c. Instill antibiotic eye drops as prescribed.
   d. Close the eyes and apply a small ice pack as prescribed to the closed eyes.
3. Preoperative care to the recipient of the cornea
   a. The recipient may be told of the tissue (cornea) availability only several hours to 1 day before the surgery.
   b. Assist in alleviating client anxiety.
   c. Assess the recipient's eye for signs of infection.
   d. Report the presence of any redness, watery or purulent drainage, or edema around the recipient's eye to the PHCP.
   e. Instill antibiotic drops into the recipient's eye as prescribed to reduce the number of microorganisms present.
   f. Administer fluids and medications intravenously as prescribed.
4. Postoperative care to the recipient
   a. The eye is covered with a patch and protective shield that is left in place for 1 day.
   b. Do not remove or change the dressing without a PHCP's prescription.
   c. Monitor vital signs.
   d. Monitor level of consciousness.
   e. Assess the eye dressing.
   f. Position the client with the head elevated and on the nonoperative side to reduce IOP.
   g. Orient the client frequently.
   h. Monitor for complications of bleeding, wound leakage, infection, and tissue rejection.
   i. Instruct the client how to apply a patch and eye shield.
   j. Instruct the client to wear the eye shield at night for 1 month and whenever around small children or pets.
   k. Advise the client not to rub the eye.
   l. Instruct the client to avoid activities that increase IOP.
5. Graft rejection (Fig. 57.3)
   a. Rejection can occur at any time.
   b. Inform the client of the signs of rejection.
   c. Signs include *r*edness, *s*welling, decreased *v*ision, and *p*ain (RSVP).
   d. The eye is treated with topical corticosteroids.

V. Infectious/Inflammatory Problems of the Eye

A. Conjunctivitis
1. Description
   a. Inflammation of the conjunctiva
   b. Also known as "pink eye" (see Chapter 35 for information on conjunctivitis)

B. Blepharitis
1. Description
   a. Inflammation of the eyelid margin
   b. Common chronic ophthalmological problem
   c. Chronic recurrent varied symptoms that involve both eyes
2. Assessment
   a. Red, swollen, or itchy eyelids
   b. Gritty or burning sensation
   c. Excessive tearing
   d. Flaking or scaling of the eyelid skin
   e. Light sensitivity
   f. Blurred vision
3. Interventions
   a. Remove or limit potential exacerbating factors (allergens, smoke, etc.)
   b. Eye lid hygiene (lid massage, lid washing, and artificial tears)
   c. Possible topical or oral antibiotics
   d. Topical glucocorticoids as prescribed
   e. Contact lenses may be worn, if comfortable

C. Hordeolum
1. Description
   a. Also known as a "stye"

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

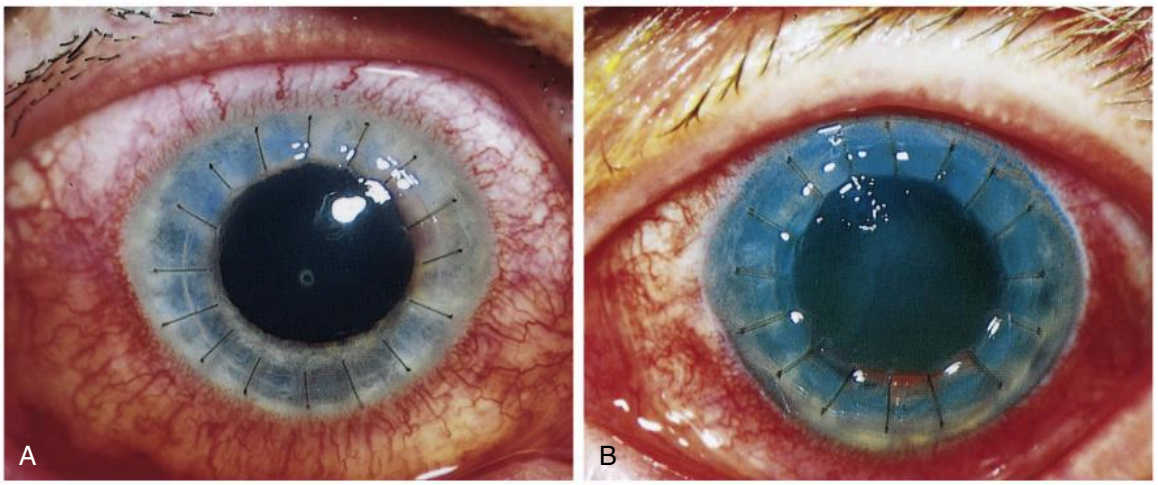

FIG. 57.3 Graft rejection. **A,** Clinical appearance of the eye after keratoplasty. **B,** Acute graft rejection. (From Black, Hawks, 2009. Courtesy Ophthalmic Photography at the University of Michigan, W.K. Kellogg Eye Center, Ann Arbor, Mich.)

   b. A red and painful lump on eyelid
   c. Caused by a gland on the edge of the eyelid becoming infected or inflamed
2. Assessment
   a. Red, painful lump on the edge of eyelid (looks like a pimple)
   b. Tearing
   c. Eyelid pain and swelling
3. Interventions
   a. Apply warm, wet compress.
   b. Wash hands often.
   c. Do not touch or rub the eye.
   d. Do not squeeze or attempt to "pop" the stye.
   e. Do not wear makeup or contact lenses.

D. Chalazion
1. Description: Painless lump in eyelid caused by blockage in lacrimal gland
2. Assessment
   a. Firm, painless lump on eyelid
   b. Red swollen lump on eyelid
3. Interventions
   a. Apply warm, wet pressure.
   b. Do not squeeze or attempt to "pop."

VI. Anatomy and Physiology of the Ear

A. Functions
1. Hearing
2. Maintenance of balance

B. External ear (pinna)
1. It is embedded in the temporal bone bilaterally at the level of the eyes.
2. It extends from the auricle through the external canal to the tympanic membrane or eardrum and includes the mastoid process, the bony ridge located over the temporal bone.

C. Middle ear
1. The middle ear consists of the medial side of the tympanic membrane.
2. It contains three bony ossicles.
   a. Malleus
   b. Incus
   c. Stapes
3. Functions of the middle ear
   a. Conduct sound vibrations from the outer ear to the central hearing apparatus in the inner ear
   b. Protect the inner ear by reducing the amplitude of loud sounds
   c. The auditory canal (eustachian tube) allows equalization of air pressure on each side of the tympanic membrane so that the membrane does not rupture.

D. Inner ear
1. The inner ear contains the semicircular canals, cochlea, and distal end of the eighth cranial nerve.
2. The semicircular canals contain fluid and hair cells connected to sensory nerve fibers of the vestibular portion of the eighth cranial nerve.
3. The inner ear maintains the sense of balance or equilibrium.
4. The cochlea is the spiral-shaped organ of hearing.
5. The organ of Corti (within the cochlea) is the receptor and organ of hearing.
6. Eighth cranial nerve
   a. The cochlear branch of the nerve transmits neuroimpulses from the cochlea to the brain, where they are interpreted as sound.
   b. The vestibular branch maintains balance and equilibrium.

E. Hearing and equilibrium
1. The external ear conducts sound waves to the middle ear.
2. The middle ear, also called the *tympanic cavity*, conducts sound waves to the inner ear.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

3. The middle ear is filled with air, which is kept at atmospheric pressure by the opening of the auditory canal.
4. The inner ear contains sensory receptors for sound and for equilibrium.
5. The receptors in the inner ear transmit sound waves and changes in body position as nerve impulses.

VII. Assessment of the Ear (see Chapter 12)

VIII. Diagnostic Tests for the Ear

A. Tomography
- **1.** Description
  - **a.** Tomography may be performed with or without contrast medium.
  - **b.** Tomography assesses the mastoid, middle ear, and inner ear structures and is especially helpful in the diagnosis of acoustic tumors.
  - **c.** Multiple radiographs of the head are obtained.
- **2.** Interventions
  - **a.** All jewelry is removed.
  - **b.** Lead eye shields are used to cover the cornea to diminish the radiation dose to the eyes.
  - **c.** The client must remain still in a supine position.
  - **d.** No follow-up care is required.
  - **e.** If contrast is to be used, assess for allergies or previous response to contrast.

B. Audiometry
- **1.** Description
  - **a.** Audiometry measures hearing acuity.
  - **b.** Audiometry uses two types, pure tone audiometry and speech audiometry.
  - **c.** Pure tone audiometry is used to identify problems with hearing, speech, music, and other sounds in the environment.
  - **d.** In speech audiometry, the client's ability to hear spoken words is measured.
  - **e.** After testing, audiographic patterns are depicted on a graph to determine the type and level of the hearing loss.
- **2.** Interventions
  - **a.** Inform the client regarding the procedure.
  - **b.** Instruct the client to identify the sounds as they are heard.

C. Electronystagmography (ENG)
- **1.** Description
  - **a.** ENG is a vestibular test that evaluates spontaneous and induced eye movements known as *nystagmus*.
  - **b.** ENG is used to distinguish between normal nystagmus and medication-induced nystagmus, or nystagmus caused by a lesion in the central or peripheral vestibular pathway.
  - **c.** ENG records changing electrical fields with the movement of the eye, as monitored by electrodes placed on the skin around the eye.

BOX 57.3 Risk Factors for Ear Problems

- Aging process
- Infection
- Medications
- Ototoxicity
- Trauma
- Tumors

- **2.** Interventions
  - **a.** The client is instructed to remain NPO (nothing by mouth) for 3 hours before testing, and to avoid caffeine-containing beverages for 24 to 48 hours before the test.
  - **b.** Unnecessary medications are withheld for 24 hours before testing.
  - **c.** Instruct the client that this is a long and tiring procedure.
  - **d.** The client should bring prescription eyeglasses to the examination.
  - **e.** The client sits and is instructed to gaze at lights, focus on a moving pattern, focus on a moving point, and then close the eyes.
  - **f.** While sitting in a chair, the client may be rotated to obtain information about vestibular function.
  - **g.** In addition, the client's ears are irrigated with cool and warm water, which may cause nausea and vomiting.
  - **h.** Following the procedure, the client begins taking clear fluids slowly and cautiously because nausea and vomiting may occur.
  - **i.** Assistance with ambulation may also be necessary following the procedure.

D. MRI: Refer to Chapter 59 for information on MRI.

IX. Problems of the Ear

A. Risk factors related to ear problems (Box 57.3)

B. **Conductive hearing loss** (Fig. 57.4)
- **1.** Description
  - **a.** Occurs when sound waves are blocked to the inner ear fibers because of external or middle ear problems
  - **b.** Problems often can be corrected with no damage to hearing or minimal permanent hearing loss.
- **2.** Causes
  - **a.** Any inflammatory process or obstruction of the external or middle ear
  - **b.** Tumors
  - **c.** **Otosclerosis**
  - **d.** A buildup of scar tissue on the ossicles from previous middle ear surgery

C. **Sensorineural hearing loss** (see Fig. 57.4)
- **1.** Description
  - **a.** A pathological process of the inner ear or of the sensory fibers that lead to the cerebral cortex
  - **b.** Sensorineural hearing loss is often permanent, and measures must be taken to reduce further damage.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

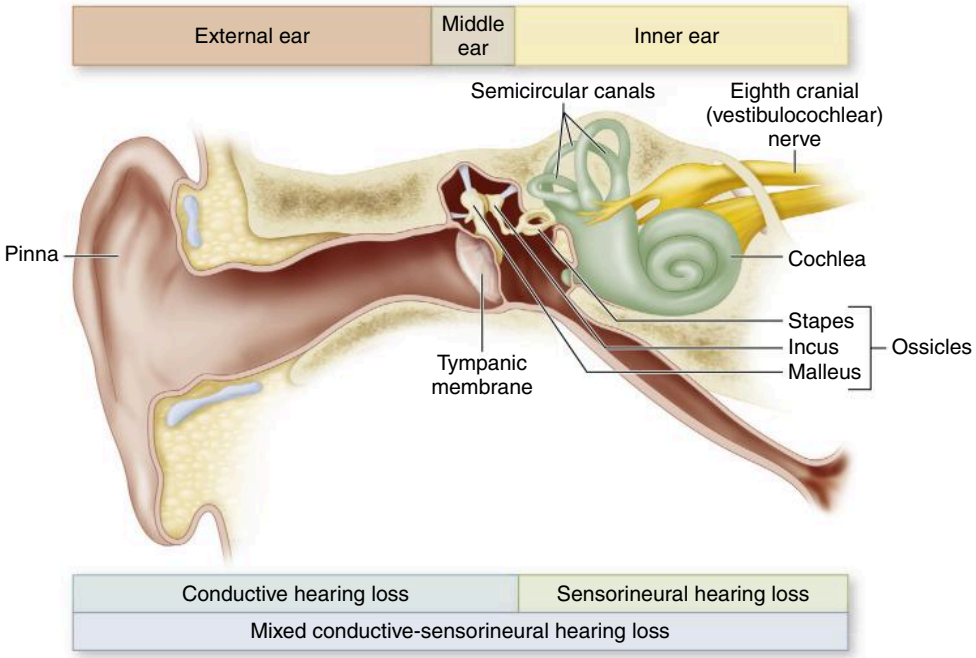

FIG. 57.4 Anatomy of hearing loss. Hearing loss can be divided into three types: (1) conductive (difficulty in the external or the middle ear); (2) sensorineural (difficulty in the inner ear or vestibulocochlear nerve); and (3) mixed conductive-sensorineural (a combination of the two).

2. Causes
   - **a.** Damage to the inner ear structures
   - **b.** Damage to the eighth cranial nerve or the brain itself
   - **c.** Prolonged exposure to loud noise
   - **d.** Medications
   - **e.** Trauma
   - **f.** Inherited problems
   - **g.** Metabolic and circulatory problems
   - **h.** Infections
   - **i.** Surgery
   - **j.** Ménière's syndrome
   - **k.** Diabetes mellitus
   - **l.** Myxedema

D. Mixed hearing loss (see Fig. 57.4)
1. Also known as conductive-sensorineural hearing loss
2. The client has both sensorineural and conductive hearing loss.

E. Central hearing loss: Involves the inability to interpret sound, including speech, due to a problem in the brain

F. Signs of hearing loss and facilitating communication (Boxes 57.4 and 57.5)

G. Cochlear implantation
1. Cochlear implants are used for sensorineural hearing loss.
2. A small computer converts sound waves into electrical impulses.
3. Electrodes are placed by the internal ear with a computer device attached to the external ear.
4. Electronic impulses directly stimulate nerve fibers.

BOX 57.4 Signs of Hearing Loss

- Frequently asking others to repeat statements
- Straining to hear
- Turning the head or leaning forward to favor one ear
- Shouting in conversation
- Ringing in the ears
- Failing to respond when not looking in the direction of the sound
- Answering questions incorrectly
- Raising the volume of the television or radio
- Avoiding large groups
- Better understanding of speech when in small groups
- Withdrawing from social interactions

H. Hearing aids
1. Used for the client with conductive hearing loss
2. Have limited value for the client with sensorineural hearing loss, because they make sounds only louder, not clearer
3. A difficulty that exists in the use of hearing aids is the amplification of background noise and voices.
4. Hearing aids are costly and often not covered by insurance. Some clients can obtain hearing aids through a rehabilitation facility or through other resources.
5. Client education (Box 57.6)

I. Presbycusis
1. Description
   - **a.** A sensorineural hearing loss associated with aging

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 57.5 Facilitating Communication

- Using written words if the client is able to see, read, and write
- Providing plenty of light in the room
- Getting the attention of the client before beginning to speak
- Facing the client when speaking
- Talking in a room without distracting noises
- Moving close to the client and speaking slowly and clearly
- Keeping hands and other objects away from the mouth when talking to the client
- Talking in normal volume and at a lower pitch because shouting is not helpful and higher frequencies are less easily heard
- Rephrasing sentences and repeating information
- Validating with the client the understanding of statements made by asking the client to repeat what was said
- Reading lips
- Encouraging the client to wear glasses when talking to someone to improve vision for lipreading
- Using sign language, which combines speech with hand movements that signify letters, words, or phrases
- Using telephone amplifiers
- Using flashing lights that are activated by the ringing of the telephone or doorbell
- Using specially trained dogs to help the client be aware of sound and alert the client to potential danger

BOX 57.6 Client Education Regarding a Hearing Aid

- Begin using the hearing aid slowly to adjust to the device.
- Adjust the volume to the minimal hearing level to prevent feedback squealing.
- Concentrate on the sounds that are to be heard and on filtering out background noise.
- Clean the ear mold and cannula per manufacturer's instructions.
- Keep the hearing aid dry.
- Turn the hearing aid off before removing from the ear to prevent squealing feedback; remove the battery when not in use.
- Keep extra batteries on hand.
- Keep the hearing aid in a safe place.
- Prevent hairsprays, oils, or other hair and face products from coming into contact with the receiver of the hearing aid.
- Instruct the client to keep the hearing aid in the proper environmental climate as recommended by the manufacturer to prolong the life of the device.

BOX 57.7 Client Education Following Myringotomy

- Avoid strenuous activities.
- Avoid rapid head movements, bouncing, or bending.
- Avoid straining on bowel movement.
- Avoid drinking through a straw.
- Avoid traveling by air.
- Avoid forceful coughing.
- Avoid contact with persons with colds.
- Avoid washing hair, showering, or getting the head wet for 1 week as prescribed.
- Use proper hand hygiene to prevent infection.
- Instruct the client to blow the nose, if needed, one side at a time with the mouth open.
- Instruct the client to keep ears dry by keeping a ball of cotton coated with petroleum jelly in the ear and to change the cotton ball daily.
- Instruct the client to report excessive ear drainage to the primary health care provider.

b. Presbycusis leads to degeneration or atrophy of the ganglion cells in the cochlea and a loss of elasticity of the basilar membranes.

c. Presbycusis leads to compromise of the vascular supply to the inner ear, with changes in several areas of the ear structure.

2. Assessment

a. Hearing loss is gradual and bilateral.

b. Client states has no problem with hearing but cannot understand what the words are.

c. Client thinks that the speaker is mumbling.

Instruct the client that cotton-tipped applicators should not be inserted into the ear canal, because their use can lead to trauma to the canal and can puncture the tympanic membrane.

J. Otitis externa: See Chapter 35.

K. Otitis media: See Chapter 35.

1. Myringotomy: See Chapter 35.

2. Client education (Box 57.7)

L. Chronic otitis media

1. Description

a. A chronic infective, inflammatory, or allergic response involving the structure of the middle ear

b. Frequent removal of debris from the ear canal may be required.

c. Myringoplasty can reconstruct the tympanic membrane and ossicles and improve conductive hearing loss.

d. Mastoidectomy may be performed if the infection has spread to involve the mastoid bone.

Monitor the client with otitis media closely for response to treatment. Otic and systemic antibiotics may be used to treat the infection, but often the organism is resistant.

2. Preoperative interventions

a. Administer antibiotic drops as prescribed.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

b. Clean the ear of debris as prescribed; irrigate the ear with a solution of equal parts vinegar and sterile water as prescribed to restore the normal pH of the ear.
c. Instruct the client to avoid persons with upper respiratory infections, obtain adequate rest, eat a balanced diet, and drink adequate fluids.
d. Instruct the client in deep breathing and coughing; forceful coughing, which increases pressure in the middle ear, is to be avoided postoperatively.

3. Postoperative interventions
   a. Inform the client that initial hearing after surgery is diminished because of the packing in the ear canal; hearing improvement will occur after the ear canal packing is removed.
   b. Keep the dressing clean and dry.
   c. Keep the client flat as prescribed, with the operative ear up for at least 12 hours.
   d. Administer antibiotics as prescribed.

M. Mastoiditis

1. Description
   a. Mastoiditis may be acute or chronic and results from untreated or inadequately treated chronic or acute otitis media.
   b. The pain is not relieved by myringotomy.
2. Assessment
   a. Swelling behind the ear and pain with minimal movement of the head
   b. Cellulitis on the skin or external scalp over the mastoid process
   c. A reddened, dull, thick, immobile tympanic membrane, with or without perforation
   d. Tender and enlarged postauricular lymph nodes
   e. Low-grade fever
3. Interventions
   a. Prepare the client for surgical removal of infected material.
   b. Simple or modified radical mastoidectomy with tympanoplasty is the most common treatment.
   c. Once infected tissue is removed, the tympanoplasty is performed to reconstruct the ossicles and tympanic membrane in an attempt to restore normal hearing.
4. Complications
   a. Damage to the abducens and facial cranial nerves; exhibited by an inability to look laterally (cranial nerve VI, abducens) and a drooping of the mouth on the affected side (cranial nerve VII, facial)
   b. Meningitis
   c. Brain abscess
   d. Chronic purulent otitis media
   e. Wound infections
   f. Vertigo, if the infection spreads into the labyrinth
5. Postoperative interventions
   a. Monitor for dizziness.
   b. Monitor for signs of meningitis, as evidenced by a stiff neck and vomiting, and for other complications.
   c. Prepare for a wound dressing change 24 hours postoperatively.
   d. Monitor the surgical incision for edema, drainage, and redness.
   e. Position the client flat with the operative side up as prescribed.
   f. Restrict the client to bed with bedside commode privileges for 24 hours as prescribed.
   g. Assist the client with getting out of bed to prevent falling or injuries from dizziness.
   h. With reconstruction of the ossicles via a graft, take precautions to prevent dislodging of the graft.

N. Otosclerosis

1. Description
   a. A genetic problem of the labyrinthine capsule of the middle ear that results in a bony overgrowth of the tissue surrounding the ossicles
   b. Otosclerosis causes the development of irregular areas of new bone formation and causes the fixation of the bones.
   c. Stapes fixation leads to a conductive hearing loss.
   d. If the disease involves the inner ear, sensorineural hearing loss is present.
   e. Bilateral involvement is common, although hearing loss may be worse in one ear.
   f. Nonsurgical intervention promotes the improvement of hearing through amplification.
   g. Surgical intervention involves removal of the bony growth causing the hearing loss.
   h. A partial stapedectomy or complete stapedectomy with prosthesis (fenestration) may be performed surgically.
2. Assessment
   a. Slowly progressing conductive hearing loss
   b. Bilateral hearing loss
   c. A ringing or roaring type of constant tinnitus
   d. Loud sounds heard in the ear when chewing
   e. Pinkish discoloration (Schwartze's sign) of the tympanic membrane, which indicates vascular changes within the ear

O. Fenestration

1. Description
   a. Removal of the stapes, with a small hole drilled in the footplate; a prosthesis is connected between the incus and footplate.
   b. Sounds cause the prosthesis to vibrate in the same manner as the stapes.
   c. Complications include complete hearing loss, prolonged vertigo, infection, and facial nerve damage.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

2. Preoperative interventions
   a. Instruct the client in measures to prevent middle ear or external ear infections.
   b. Instruct the client to avoid excessive nose blowing.
3. Postoperative interventions
   a. Inform the client that hearing is initially worse after the surgical procedure because of swelling and that no noticeable improvement in hearing may occur for as long as 6 weeks.
   b. Inform the client that the Gelfoam ear packing (if used) interferes with hearing but is used to decrease bleeding.
   c. Assist with ambulating during the first 1 to 2 days after surgery.
   d. Administer antibiotic, antivertiginous, and pain medications as prescribed.
   e. Assess for facial nerve damage, weakness, changes in tactile sensation and taste sensation, vertigo, nausea, and vomiting.
   f. Instruct the client to move the head slowly when changing positions to prevent vertigo.
   g. Instruct the client to avoid persons with upper respiratory infections.
   h. Instruct the client to avoid showering and getting the head and wound wet.
   i. Instruct the client to avoid rapid extreme changes in pressure caused by quick head movements, sneezing, nose blowing, straining, and changes in altitude.
   j. Instruct the client to avoid changes in middle ear pressure, because they could dislodge the graft or prosthesis.

P. Labyrinthitis

1. Description: Infection of the labyrinth that occurs as a complication of acute or chronic otitis media
2. May result from growth of a cholesteatoma, a benign overgrowth of squamous cell epithelium in the middle ear
3. Assessment
   a. Hearing loss that may be permanent on the affected side
   b. Tinnitus
   c. Spontaneous nystagmus to the affected side
   d. Vertigo
   e. Nausea and vomiting
4. Interventions
   a. Monitor for signs of meningitis, the most common complication, as evidenced by headache, stiff neck, and lethargy.
   b. Administer systemic antibiotics as prescribed.
   c. Advise the client to rest in bed in a darkened room.
   d. Administer antiemetics and antivertiginous medications as prescribed.
   e. Instruct the client that the vertigo subsides as the inflammation resolves.
   f. Instruct the client that balance problems that persist may require gait training through physical therapy.

Q. Ménière's syndrome

1. Description
   a. Also called endolymphatic hydrops; it refers to dilation of the endolymphatic system by overproduction or decreased reabsorption of endolymphatic fluid.
   b. The syndrome is characterized by tinnitus, unilateral sensorineural hearing loss, and vertigo.
   c. Symptoms occur in attacks and last for several days, and the client becomes totally incapacitated during the attacks.
   d. Initial hearing loss is reversible, but as the frequency of attacks increases, hearing loss becomes permanent.

⚠ A priority nursing intervention in the care of a client with Ménière's syndrome is to institute safety measures.

2. Causes
   a. Any factor that increases endolymphatic secretion in the labyrinth
   b. Viral and bacterial infections
   c. Allergic reactions
   d. Biochemical disturbances
   e. Vascular disturbance, producing changes in the microcirculation in the labyrinth
   f. Long-term stress may be a contributing factor.
3. Assessment
   a. Feelings of fullness in the ear
   b. Tinnitus, as a continuous low-pitched roar or humming sound, that is present much of the time but worsens just before and during severe attacks
   c. Hearing loss that is worse during an attack
   d. Vertigo; that is, a sensation of whirling that might cause the client to fall to the ground
   e. Vertigo that is so intense that even while lying down, the client holds the bed or ground in an attempt to prevent the whirling
   f. Nausea and vomiting
   g. Nystagmus
   h. Severe headaches
4. Nonsurgical interventions
   a. Prevent injury during vertigo attacks.
   b. Provide bed rest in a quiet environment.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

c. Provide assistance with walking.
d. Instruct the client to move the head slowly to prevent worsening of the vertigo.
e. Initiate sodium and fluid restrictions as prescribed.
f. Instruct the client to stop smoking.
g. Instruct the client to avoid watching television because the flickering of lights may exacerbate symptoms.
h. Administer nicotinic acid as prescribed for its vasodilatory effect.
i. Administer antihistamines as prescribed to reduce the production of histamine and the inflammation.
j. Administer antiemetics as prescribed.
k. Administer tranquilizers and sedatives as prescribed to calm the client; allow the client to rest; and control vertigo, nausea, and vomiting.
l. Mild diuretics may be prescribed to decrease endolymph volume.
m. Inform the client about vestibular rehabilitation as prescribed.

5. Surgical interventions
   a. Surgery is performed when medical therapy is ineffective and the functional level of the client has decreased significantly.
   b. Endolymphatic drainage and insertion of a shunt may be an option early in the course of the disease to assist with the drainage of excess fluids.
   c. A resection of the vestibular nerve or total removal of the labyrinth (i.e., a labyrinthectomy) may be performed.
6. Postoperative interventions
   a. Assess packing and dressing on the ear.
   b. Speak to the client on the side of the unaffected ear.
   c. Perform neurological assessments.
   d. Maintain safety.
   e. Assist with ambulating.
   f. Encourage the client to use a bedside commode rather than ambulating to the bathroom.
   g. Administer antivertiginous and antiemetic medications as prescribed.

R. Acoustic neuroma
1. Description
   a. A benign tumor of the vestibular or acoustic nerve
   b. The tumor may cause damage to hearing and to facial movements and sensations.
   c. Treatment includes surgical removal of the tumor via craniotomy.
   d. Care is taken to preserve the function of the facial nerve.
   e. The tumor rarely recurs after surgical removal.
   f. Postoperative nursing care is similar to postoperative craniotomy care.
2. Assessment
   a. Symptoms usually begin with tinnitus and progress to gradual sensorineural hearing loss.
   b. As the tumor enlarges, damage to adjacent cranial nerves occurs.

S. Trauma
1. Description
   a. The tympanic membrane has limited stretching ability and gives way under high pressure.
   b. Foreign objects placed in the external canal may exert pressure on the tympanic membrane and cause perforation.
   c. If the object continues through the canal, the bony structure of the stapes, incus, and malleus may be damaged.
   d. A blunt injury to the basal skull and ear can damage the middle ear structures through fractures extending to the middle ear.
   e. Excessive nose blowing and rapid changes of pressure that occur with nonpressurized air flights can increase pressure in the middle ear.
   f. Depending on the damage to the ossicles, hearing loss may or may not be reversible.
2. Interventions
   a. Tympanic membrane perforations usually heal within 24 hours.
   b. Surgical reconstruction of the ossicles and tympanic membrane through tympanoplasty or myringoplasty may be performed to improve hearing.

T. Cerumen and foreign bodies
1. Description
   a. Cerumen, or wax, is the most common cause of impacted canals.
   b. Foreign bodies can include vegetables, beads, pencil erasers, insects, and other objects.
2. Assessment
   a. Sensation of fullness in the ear with or without hearing loss
   b. Pain, itching, or bleeding
3. Cerumen
   a. Removal of wax may be done by irrigation.
   b. Irrigation is contraindicated in clients with a history of tympanic membrane perforation or otitis media.
   c. If prescribed to soften cerumen, glycerin or mineral oil is placed in the ear at bedtime; hydrogen peroxide may also be prescribed.
   d. After several days, the ear is irrigated.
   e. The maximum amount of solution that should be used for irrigation is 50 to 70 mL.

Telegram & Insta: NCLEX_RN_Edu

⚠ Inform the client that ear candles should never be used to remove cerumen. Their use can cause burns and a vacuum effect, causing a perforation in the tympanic membrane.

4. Foreign bodies
   - **a.** With a foreign object of vegetable matter, irrigation is used with care, because this material expands with hydration.
   - **b.** Insects are killed before removal, unless they can be coaxed out by flashlight or a humming noise; lidocaine may be placed in the ear to relieve pain.
   - **c.** Mineral oil or diluted alcohol is instilled to suffocate the insect, which then is removed using ear forceps.
   - **d.** Use a small ear forceps to remove the object; avoid pushing the object farther into the canal and damaging the tympanic membrane.

PRACTICE QUESTIONS

1. During the early postoperative period, a client who has undergone a cataract extraction complains of nausea and severe eye pain over the operative site. What would be the **initial** nursing action?
   1. Call the surgeon.
   2. Reassure the client that this is normal.
   3. Turn the client onto their operative side.
   4. Administer the prescribed pain medication and antiemetic.

2. The nurse is developing a teaching plan for a client with glaucoma. Which instruction would the nurse include in the plan of care?
   1. Avoid overuse of the eyes.
   2. Decrease the amount of salt in the diet.
   3. Eye medications will need to be administered for life.
   4. Decrease fluid intake to control the intraocular pressure.

3. The nurse is performing an admission assessment on a client with a diagnosis of detached retina. Which sign or symptom is associated with this eye problem?
   1. Total loss of vision
   2. Pain in the affected eye
   3. A yellow discoloration of the sclera
   4. A sense of a curtain falling across the field of vision

4. The nurse is performing an otoscopic examination on a client with mastoiditis. On examination of the tympanic membrane, which finding would the nurse expect to observe?
   1. A pink-colored tympanic membrane
   2. A pearly colored tympanic membrane
   3. A transparent and clear tympanic membrane
   4. A red, dull, thick, and immobile tympanic membrane

5. A client is diagnosed with a problem involving the inner ear. Which is the **most** common client complaint associated with a problem involving this part of the ear?
   1. Pruritus
   2. Tinnitus
   3. Hearing loss
   4. Burning in the ear

6. The nurse is performing an assessment on a client with a suspected diagnosis of cataract. Which clinical manifestation would the nurse expect to note in the **early** stages of cataract formation?
   1. Diplopia
   2. Eye pain
   3. Floating spots
   4. Blurred vision

7. A client arrives in the emergency department following an automobile crash. The client's forehead hit the steering wheel, and a hyphema is diagnosed. The nurse would place the client in which position?
   1. Flat in bed
   2. A semi-Fowler's position
   3. Lateral on the affected side
   4. Lateral on the unaffected side

8. The client sustains a contusion of the eyeball following a traumatic injury with a blunt object. Which intervention would be initiated **immediately**?
   1. Apply ice to the affected eye.
   2. Irrigate the eye with cool water.
   3. Notify the primary health care provider (PHCP).
   4. Accompany the client to the emergency department.

9. A client arrives in the emergency department with a penetrating eye injury from wood chips that occurred while cutting wood. The nurse assesses the eye and notes a piece of wood protruding from the eye. What is the **initial** nursing action?
   1. Apply an eye patch.
   2. Perform visual acuity tests.
   3. Irrigate the eye with sterile saline.
   4. Remove the piece of wood using a sterile eye clamp.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

10. The nurse is caring for a client following enucleation to treat an ocular tumor and notes the presence of bright red drainage on the dressing. Which action would the nurse take at this time?
1. Document the finding.
2. Continue to monitor the drainage.
3. Notify the primary health care provider (PHCP).
4. Mark the drainage on the dressing and monitor for any increase in bleeding.

11. A client was working in the garden when insecticide accidentally sprayed into the right eye. The client calls the emergency department, frantic and screaming for help. The nurse would instruct the client to take which **immediate** action?
1. Irrigate the eyes with water.
2. Come to the emergency department.
3. Call the primary health care provider (PHCP).
4. Irrigate the eyes with diluted hydrogen peroxide.

12. The nurse is preparing a teaching plan for a client who had a cataract extraction with intraocular implantation. Which home care measures would the nurse include in the plan? **Select all that apply.**
- ❑ 1. Avoid activities that require bending over.
- ❑ 2. Contact the surgeon if eye scratchiness occurs.
- ❑ 3. Take acetaminophen for minor eye discomfort.
- ❑ 4. Expect episodes of sudden severe pain in the eye.
- ❑ 5. Place an eye shield on the surgical eye at bedtime.
- ❑ 6. Contact the surgeon if a decrease in visual acuity occurs.

13. Tonometry is performed on a client with a suspected diagnosis of glaucoma. The nurse looks at the documented test results and notes an intraocular pressure (IOP) value of 23. What would be the nurse's **initial** action?
1. Apply normal saline drops.
2. Note the time of day the test was done.
3. Contact the primary health care provider (PHCP).
4. Instruct the client to sleep with the head of the bed flat.

14. The nurse is caring for a client following craniotomy for removal of an acoustic neuroma. Assessment of which cranial nerve would identify a complication specifically associated with this surgery?
1. Cranial nerve I, olfactory
2. Cranial nerve IV, trochlear
3. Cranial nerve III, oculomotor
4. Cranial nerve VII, facial nerve

15. The nurse notes that the primary health care provider has documented a diagnosis of presbycusis on a client's chart. Based on this information, what action would the nurse take?
1. Speak loudly but mumble or slur the words.
2. Speak loudly and clearly while facing the client.
3. Speak at normal tone and pitch, slowly and clearly.
4. Speak loudly and directly into the client's affected ear.

16. A client with Ménière's disease is experiencing severe vertigo. Which instruction would the nurse give to the client to assist in controlling the vertigo?
1. Increase sodium in the diet.
2. Avoid sudden head movements.
3. Lie still and watch the television.
4. Increase fluid intake to 3000 mL a day.

17. The nurse is preparing to test the visual acuity of a client, using a Snellen chart. Which identifies the accurate procedure for this visual acuity test?
1. The right eye is tested, followed by the left eye, and then both eyes are tested.
2. Both eyes are assessed together, followed by an assessment of the right eye and then the left eye.
3. The client is asked to stand at a distance of 40 feet (12 meters) from the chart and to read the largest line on the chart.
4. The client is asked to stand at a distance of 40 feet (12 meters) from the chart and to read the line that can be read 200 feet (60 meters) away by an individual with unimpaired vision.

18. A client's vision is tested with a Snellen chart. The results of the tests are documented as 20/60. What action would the nurse implement based on this finding?
1. Provide the client with materials on legal blindness.
2. Instruct the client that glasses may be needed when driving.
3. Inform the client of where to purchase a white cane with a red tip.
4. Inform the client that it is best to sit near the back of the room when attending lectures.

19. The nurse is caring for a hearing-impaired client. Which approach will facilitate communication?
1. Speak loudly.
2. Speak frequently.
3. Speak at a normal volume.
4. Speak directly into the impaired ear.

Telegram & Insta: NCLEX_RN_Edu

ANSWERS

1. *Answer:* 1
Rationale: Severe pain or pain accompanied by nausea following a cataract extraction is an indicator of increased intraocular pressure and would be reported to the surgeon immediately. Options 2, 3, and 4 are inappropriate actions.
Test-Taking Strategy: Note the **strategic word**, *initial*, and the word *severe*. Eliminate option 2 because this is not a normal condition. The client would not be turned to the operative side; therefore, eliminate option 3. From the remaining options, focusing on the **strategic word** will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 941.

2. *Answer:* 3
Rationale: The administration of eye drops is a critical component of the treatment plan for the client with glaucoma. Clients with glaucoma need to be instructed that medications will need to be taken for the rest of their lives. Options 1, 2, and 4 are inaccurate instructions.
Test-Taking Strategy: Focus on the **subject**, client teaching for glaucoma. Recalling that medications are an integral component of the treatment plan will assist in directing you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 943-945.

3. *Answer:* 4
Rationale: A characteristic manifestation of retinal detachment described by the client is the feeling that a shadow or curtain is falling across the field of vision. No pain is associated with detachment of the retina. Options 1 and 3 are not characteristics of this problem. A retinal detachment is an ophthalmic emergency, and even more so if visual acuity is still normal.
Test-Taking Strategy: Focus on the **subject,** manifestations of retinal detachment. Thinking about the pathophysiology associated with this problem will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 948-949.

4. *Answer:* 4
Rationale: Otoscopic examination in a client with mastoiditis reveals a red, dull, thick, and immobile tympanic membrane, with or without perforation. Postauricular lymph nodes are tender and enlarged. Clients also have a low-grade fever, malaise, anorexia, swelling behind the ear, and pain with minimal movement of the head.
Test-Taking Strategy: Focus on the **subject,** the assessment findings in mastoiditis. Think about the pathophysiology associated with mastoiditis, and remember that mastoiditis reveals a red, dull, thick, and immobile tympanic membrane.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 967.

5. *Answer:* 2
Rationale: Tinnitus is the most common complaint of clients with otological problems, especially problems involving the inner ear. Symptoms of tinnitus range from mild ringing in the ear, which can go unnoticed during the day, to a loud roaring in the ear, which can interfere with the client's thinking process and attention span. Options 1, 3, and 4 are not associated specifically with problems of the inner ear.
Test-Taking Strategy: Note the **strategic word,** *most.* Recalling the anatomy and the function of the inner ear will direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 967-968.

6. *Answer:* 4
Rationale: A gradual, painless blurring of central vision is the chief clinical manifestation of a cataract. Early symptoms include slightly blurred vision and a decrease in color perception. Options 1, 2, and 3 are not characteristics of a cataract.
Test-Taking Strategy: Note the **strategic word,** *early.* Remember the pathophysiology related to cataract development. As a cataract develops, the lens of the eye becomes opaque. This description will assist in directing you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 939.

7. *Answer:* 2
Rationale: A hyphema is the presence of blood in the anterior chamber. Hyphema is produced when a force is sufficient to break the integrity of the blood vessels in the eye and can be caused by direct injury, such as a penetrating injury from a BB or pellet, or indirectly, such as from striking the forehead on a steering wheel during an accident. The client is treated by bed rest in a semi-Fowler's position to assist gravity in keeping the hyphema away from the optical center of the cornea.
Test-Taking Strategy: Focus on the **subject,** care of the client who has sustained a hyphema. Remember that placing the client flat will produce an increase in pressure at the injured site. Also, note that the correct option is the one that identifies a position different from the other options.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 361; Jarvis, C. (2020). *Physical examination and health assessment.* (8th ed.). St. Louis: Elsevier. p. 313.

8. *Answer:* 1
Rationale: Treatment for a contusion begins at the time of injury. Ice is applied immediately. The client then needs to be seen by a PHCP and receive a thorough eye examination to rule out the presence of other eye injuries.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

Test-Taking Strategy: Focus on the **strategic word,** *immediately*. Recalling the principles related to initial treatment of injuries and noting the type of injury sustained will direct you to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 161, 361.

9. *Answer:* 2
Rationale: If the eye injury is the result of a penetrating object, the object may be noted protruding from the eye. This object must never be removed except by the ophthalmologist, because it may be holding ocular structures in place. Application of an eye patch or irrigation of the eye may disrupt the foreign body and cause further tearing of the cornea.
Test-Taking Strategy: Note the **strategic word,** *initial*, and note the word *penetrating*. This would indicate that a laceration has occurred and that interventions are directed at preventing further disruption of the integrity of the eye. The only option that will prevent further disruption is to assess visual acuity.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 950.

10. *Answer:* 3
Rationale: If the nurse notes the presence of bright red drainage on the dressing, it must be reported to the PHCP, because this indicates hemorrhage. Options 1, 2, and 4 are inappropriate at this time.
Test-Taking Strategy: Determine if an **abnormality exists**. Note the words *bright red*. Since an abnormality does exist, eliminate options that state to document and continue to monitor because an action is needed.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 373.

11. *Answer:* 1
Rationale: In this type of accident, the client is instructed to irrigate the eyes immediately with running water for at least 20 minutes, or until the emergency medical services personnel arrive. In the emergency department, the cleansing agent of choice is usually normal saline. Calling the PHCP or going to the emergency department delays necessary intervention. Hydrogen peroxide is never placed in the eyes.
Test-Taking Strategy: Note the **strategic word,** *immediate*. Focus on the type of injury, and eliminate options 2 and 3 because they delay necessary intervention. Next, eliminate option 4 because hydrogen peroxide is never placed in the eyes.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 361.

12. *Answer:* 1, 3, 5, 6
Rationale: Following eye surgery, some scratchiness and mild eye discomfort may occur in the operative eye; this is usually relieved by mild analgesics. If the eye pain becomes severe, the client would notify the surgeon, because this may indicate hemorrhage, infection, or increased intraocular pressure (IOP). The nurse also would instruct the client to notify the surgeon of increased purulent drainage, increased redness, or any decrease in visual acuity. The client is instructed to place an eye shield over the operative eye at bedtime to protect the eye from injury during sleep and to avoid activities that increase IOP, such as bending over.
Test-Taking Strategy: Focus on the **subject,** postoperative care for eye surgery. Recalling that the eye needs to be protected and that increased IOP is a concern will assist in determining the home care measures to be included in the plan.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 366.

13. *Answer:* 2
Rationale: Tonometry is a method of measuring intraocular fluid pressure. Pressures between 10 and 21 mm Hg are considered within the normal range. However, IOP is slightly higher in the morning. Therefore, the initial action is to check the time the test was performed. Normal saline drops are not a specific treatment for glaucoma. It is unnecessary to contact the PHCP as an initial action. Flat positions may increase the pressure.
Test-Taking Strategy: Focus on the **subject,** normal IOP, and note the **strategic word,** *initial*. Remember that normal IOP is between 10 and 21 mm Hg and that pressure may be higher in the morning.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 943.

14. *Answer:* 4
Rationale: An acoustic neuroma (or vestibular schwannoma) is a unilateral benign tumor that occurs where the vestibulocochlear or acoustic nerve (cranial nerve VIII) enters the internal auditory canal. It is important that an early diagnosis be made, because the tumor can compress the trigeminal and facial nerves and arteries within the internal auditory canal. Treatment for acoustic neuroma is surgical removal via a craniotomy. Assessment of the trigeminal and facial nerves is important. Extreme care is taken to preserve remaining hearing and preserve the function of the facial nerve. Acoustic neuromas rarely recur after surgical removal.
Test-Taking Strategy: Focus on the **subject,** a complication after surgery. Think about the anatomical location of an acoustic neuroma and the nerves that the neuroma can compress to direct you to the correct option.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 969.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

15. *Answer:* 3

Rationale: Presbycusis is a type of hearing loss that occurs with aging. Presbycusis is a gradual sensorineural loss caused by nerve degeneration in the inner ear or auditory nerve. When communicating with a client with this condition, the nurse would speak at a normal tone and pitch, slowly and clearly. It is inappropriate to speak loudly, to mumble or slur words, or to speak into the client's affected ear.

Test-Taking Strategy: Focus on the **subject,** presbycusis and the effective method to communicate. Visualize each of the communication techniques to direct you to the correct option.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 956, 958.

16. *Answer:* 2

Rationale: The nurse instructs the client to make slow head movements to prevent worsening of the vertigo. Dietary changes such as salt and fluid restrictions that reduce the amount of endolymphatic fluid are sometimes prescribed. Lying still and watching television will not control vertigo.

Test-Taking Strategy: Focus on the **subject,** preventing vertigo. Note the relationship between vertigo and the words *avoid sudden head movements* in the correct option.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 968.

17. *Answer:* 1

Rationale: Visual acuity is assessed in one eye at a time, and then in both eyes together, with the client comfortably standing or sitting. The right eye is tested with the left eye covered; then the left eye is tested with the right eye covered. Both eyes are then tested together. Visual acuity is measured with or without corrective lenses, and the client stands at a distance of 20 feet (6 meters) from the chart.

Test-Taking Strategy: Remember that normal visual acuity as measured by a Snellen chart is 20/20 vision. This will assist in eliminating options 3 and 4, because they are **comparable or alike** in that they indicate standing at a distance of 40 feet (12 meters). From the remaining options, remember that it is best and most accurate to test each eye separately and then to test both eyes together.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 355-356.

18. *Answer:* 2

Rationale: Vision that is 20/20 is normal—that is, the client is able to read from 20 feet (6 meters) what a person with normal vision can read from 20 feet (6 meters). A client with a visual acuity of 20/60 can only read at a distance of 20 feet (6 meters) what a person with normal vision can read at 60 feet (18 meters). With this vision, the client may need glasses while driving in order to read signs and to see far ahead. The client needs to be instructed to sit in the front of the room for lectures to aid in visualization. This is not considered to be legal blindness.

Test-Taking Strategy: Focus on the **subject,** interpreting a Snellen chart result. Note the test result, 20/60, and recall the associated interventions for this result. Also, eliminate options 1 and 3, as they are **comparable or alike**, implying that the test results indicate blindness.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 355-356.

19. *Answer:* 3

Rationale: Speaking in a normal tone to the client with impaired hearing and not shouting are important. The nurse would talk directly to the client while facing the client and speak clearly. If the client does not seem to understand what is said, the nurse would express it differently. Moving closer to the client and toward the better ear may facilitate communication, but the nurse would avoid talking directly into the impaired ear.

Test-Taking Strategy: Focus on the **subject,** an effective communication technique for the hearing impaired. Remember that it is important to speak in a normal tone.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 958.

CHAPTER 58

Eye and Ear Medications

Contributors: David Petersen, MSN-Ed, RN
James Guilbault, PharmD, BS, RPh

Telegram & Insta: NCLEX_RN_Edu

PRIORITY CONCEPTS **Safety; Sensory Perception**

I. Ophthalmic Medication Administration

A. Guidelines for the use of eye medications

1. Eye medications are usually in the form of drops or ointments.
2. To prevent overflow of medication into the nasal and pharyngeal passages, thus reducing systemic absorption, instruct the client to apply pressure over the inner canthus next to the nose for 30 to 60 seconds following administration of the medication; instruct the client to close the eye gently to help distribute the medication (Fig. 58.1).
3. If both an eye drop and eye ointment are scheduled to be administered at the same time, administer the eye drop first.
4. Wash hands and don gloves before administering eye medications to avoid contaminating the eye or medication dropper or applicator.
5. Use a separate bottle or tube of medication for each client to avoid accidental cross- contamination.
6. Place the prescribed dose of eye medication in the lower conjunctival sac, never directly onto the cornea.
7. Avoid touching any part of the eye with the dropper or applicator.
8. Administer glucocorticoid preparations before other medications.
9. Monitor the pulse and blood pressure if the client is receiving an ophthalmic beta blocker, and instruct the client to do the same; the nurse should obtain pulse parameters from the primary health care provider (PHCP).
10. Instruct the client how to instill medication correctly, and supervise instillation until the client can do it safely; adaptive devices that position the bottle of eye drops directly over the eye can also be purchased if instillation is difficult for the client. (See Clinical Judgment: Generate Solutions Box.)
11. Instruct the client to read the medication labels carefully to ensure administration of the correct medication and correct strength.
12. Remind the client to keep these medications out of the reach of children.
13. Instruct the client to avoid driving or operating hazardous equipment if vision is blurred.
14. Inform clients that they may be unable to drive home after eye examinations when a medication to dilate the pupil (**mydriatic**) or to paralyze the ciliary muscle (**cycloplegic**) is used.
15. If photophobia occurs, instruct the client to wear sunglasses and avoid bright lights.
16. Instruct the client to administer a missed dose of the eye medication as soon as it is remembered, unless the next dose is scheduled to be administered in 1 to 2 hours.
17. Inform the client with **glaucoma** that the disorder cannot be cured, only controlled.
18. Reinforce the importance of using medications to treat glaucoma as prescribed and not to discontinue these medications without consulting the PHCP.
19. Inform the client that medications used to treat glaucoma may cause stinging or pain and blurred vision, especially when therapy is begun.

Telegram & Insta: NCLEX_RN_Edu

FIG. 58.1 Applying punctual occlusion to prevent systemic absorption of eye drops. (Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 946.)

CLINICAL JUDGMENT: GENERATE SOLUTIONS

A 79-year-old client who requires the instillation of eye drops 3 times daily tells the nurse about living alone and concern about the ability to administer the drops because of shaky hands. The nurse creates a plan of care and generates solutions that include the following:

- Assist with the arrangement of a home care nurse to assess the client and the home situation.
- Explore the possibility that a friend, neighbor, or family member can be taught the technique and administer the client's eye drops.
- Explore potential adaptive equipment that positions the bottle of eye drops directly over the eye to facilitate ease for the client to instill the eye drops.

20. Instruct the client to report the development of any eye irritation.
21. Inform the client using eye gel to store the gel at room temperature or in the refrigerator, but not to freeze it.
22. Instruct the client to discard unused eye gel kept at room temperature as recommended by the PHCP and/or the pharmacist.
23. Inform the client that soft contact lenses may absorb certain eye medications and that preservatives in eye medications may discolor the contact lenses.
24. Advise the client wearing contact lenses to question the PHCP carefully about special precautions to observe with eye medications.
25. Inform the parents of infants that atropine sulfate eye drops may contribute to abdominal distention.
26. Instruct the parents to keep a record of the infant's bowel movements if atropine sulfate eye drops are being administered.
27. Auscultate bowel sounds of the infant or child receiving atropine sulfate eye drops.

! Because the timing of medication administration is critical, administer eye medications at precise intervals as prescribed; separate the instillation by 5 to 10 minutes if two different medications must be administered at the same time.

B. Instillation of eye medications

1. Drops
   - **a.** Wash hands.
   - **b.** Put gloves on.
   - **c.** Check the name, strength, and expiration date of the medication.
   - **d.** Instruct the client to tilt the head backward, open the eyes, and look up.
   - **e.** Pull the lower lid down against the cheekbone.
   - **f.** Hold the bottle like a pencil, with the tip downward.
   - **g.** Holding the bottle, gently rest the wrist of the hand on the client's cheek.
   - **h.** Squeeze the bottle gently to allow the drop to fall into the conjunctival sac.
   - **i.** Instruct the client to close the eyes gently and not to squeeze the eyes shut.
   - **j.** Wait 3 to 5 minutes before instilling another drop, if more than one drop is prescribed, to promote maximal absorption of the medication.
   - **k.** Do not allow the medication bottle, dropper, or applicator to come into contact with the eyelid or conjunctival sac.
   - **l.** To prevent systemic absorption of the medication, apply gentle pressure with a clean tissue to the client's nasolacrimal duct for 30 to 60 seconds (see Fig. 58.1).
2. Ointments
   - **a.** Instruct the client to lie down or tilt the head backward and look up.
   - **b.** Hold the ointment tube near, but not touching, the eye or eyelashes. This action prevents the spread of contaminants from one eye to the other.
   - **c.** Squeeze a thin ribbon of ointment along the lining of the lower conjunctival sac, from the inner to the outer canthus.
   - **d.** Instruct the client to close the eyes gently, rolling the eyeball in all directions (increases contact area of medication to eye).
   - **e.** Instruct the client that vision may be blurred by the ointment.
   - **f.** If possible, apply ointment just before bedtime.

BOX 58.1 Mydriatic, Cycloplegic, and Anticholinergic Medications

- Atropine
- Cyclopentolate
- Homatropine
- Phenylephrine
- Scopolamine
- Tropicamide

BOX 58.2 Antiinfective Eye Medications

Antibacterial
- Bacitracin
- Chloramphenicol
- Erythromycin
- Moxifloxacin
- Ofloxacin
- Trimethoprim-polymyxin B

Aminoglycosides
- Gentamicin sulfate
- Tobramycin

Antifungal
- Natamycin

Antiviral
- Ganciclovir
- Trifluridine

Sulfonamide
- Sulfacetamide

II. Mydriatic, Cycloplegic, and Anticholinergic Medications (Box 58.1)

A. Description
1. Mydriatics and cycloplegics dilate the pupils (mydriasis) and relax the ciliary muscles (cycloplegia).
2. Anticholinergics block responses of the sphincter muscle in the ciliary body, producing mydriasis and cycloplegia.
3. These medications are used preoperatively or for eye examinations to produce mydriasis.
4. Mydriatics are contraindicated in glaucoma, cardiac dysrhythmias, and cerebral atherosclerosis and should be used with caution in the older client and in clients with prostatic hypertrophy, diabetes mellitus, or parkinsonism.

B. Side and adverse effects
1. Tachycardia
2. Photophobia
3. Conjunctivitis
4. Dermatitis
5. Elevated blood pressure

C. Atropine toxicity
1. Dry mouth
2. Blurred vision
3. Photophobia
4. Tachycardia
5. Fever
6. Urinary retention
7. Constipation
8. Headache, brow pain
9. Worsening of glaucoma
10. Confusion
11. Hallucinations, delirium
12. Coma

D. Systemic reactions to anticholinergics
1. Dry mouth and skin
2. Fever
3. Thirst
4. Hyperactivity
5. Confusion

E. Interventions
1. Monitor for allergic response.
2. Assess for risk of injury.
3. Assess for constipation and urinary retention.
4. Instruct the client that a burning sensation may occur on instillation.
5. Instruct the client not to drive or perform hazardous activities for 24 hours after instillation of the medication unless otherwise directed by the PHCP.
6. Instruct the client to wear sunglasses until the effects of the medication wear off.
7. Instruct the client to notify the PHCP if blurring of vision, loss of sight, difficulty breathing, sweating, or flushing occurs.
8. Instruct the client to report eye pain to the PHCP.

Mydriatics are contraindicated in clients with glaucoma because of the risk of increased intraocular pressure.

III. Antiinfective Eye Medications (Box 58.2)

A. Description: Antiinfective medications kill or inhibit the growth of bacteria, fungi, and viruses.

B. Side and adverse effects
1. Superinfection
2. Local irritation

C. Interventions
1. Assess for risk of injury.
2. Instruct the client in how to apply the eye medication; remind the client to clean exudates from the eyes before administering the medication.
3. Reinforce the importance of completing the prescribed medication regimen.
4. Instruct the client to wash the hands thoroughly and frequently.
5. Advise the client to notify the PHCP if improvement does not occur.

IV. Antiinflammatory Eye Medications (Box 58.3)

A. Description
1. Antiinflammatory medications control inflammation, thereby reducing vision loss and scarring.
2. Antiinflammatory medications are used for uveitis, allergic conditions, and inflammation of the conjunctiva, cornea, and lids.

Telegram & Insta: NCLEX_RN_Edu

BOX 58.3 Antiinflammatory Eye Medications

Corticosteroids
- Dexamethasone
- Difluprednate
- Fluocinolone
- Fluorometholone
- Loteprednol etabonate
- Prednisolone
- Triamcinolone

Ophthalmic Immunosuppressant and Antiinflammatory Agent
- Cyclosporine

Nonsteroidal Antiinflammatory Agents
- Bromfenac
- Diclofenac
- Flurbiprofen sodium
- Ketorolac tromethamine
- Nepafenac

Mast Cell Stabilizers
- Azelastine hydrochloride
- Cromolyn sodium
- Epinastine
- Ketotifen fumarate
- Nedocromil sodium
- Olopatadine hydrochloride

Lymphocyte Function-Associated Antigen 1 (LFA-1) Antagonists
- Lifitegrast

B. Side and adverse effects
1. Cataracts
2. Glaucoma, or increased intraocular pressure
3. Impaired healing
4. Masking signs and symptoms of infection

C. Interventions
1. Interventions are the same as for antiinfective medications.
2. Note that dexamethasone should not be used for eye abrasions and wounds.

V. Topical Eye Anesthetics

A. Description
1. Topical anesthetics produce corneal anesthesia.
2. Topical anesthetics are used for anesthesia for eye examinations and surgery or to remove foreign bodies from the eye.
3. Do not use the solution if it is discolored, and store the bottle tightly closed.
4. An example is tetracaine.

B. Side and adverse effects
1. Temporary stinging or burning of the eye
2. Temporary loss of corneal reflex

C. Interventions
1. Assess for risk of injury.

BOX 58.4 Eye Lubricants
- Carboxymethylcellulose
- Hydroxypropyl methylcellulose
- Petroleum-based ointment
- Polyvinyl alcohol

2. Note that the medications should not be given to the client for home use and are not to be self-administered by the client.
3. Instruct the client not to rub or touch the eye while it is anesthetized.
4. Note that the blink reflex is lost temporarily and that the corneal epithelium needs to be protected.
5. Provide an eye patch to protect the eye from injury until the corneal reflex returns.

VI. Eye Lubricants (Box 58.4)

A. Description
1. Eye lubricants replace tears or add moisture to the eyes.
2. Eye lubricants moisten contact lenses or an artificial eye and protect the eyes during surgery or diagnostic procedures.
3. Eye lubricants are used for keratitis, during anesthesia, or for a client who is unconscious or has decreased blinking.

B. Side and adverse effects
1. Burning on instillation
2. Discomfort or pain on instillation
3. Allergic reaction

C. Interventions
1. Inform the client that burning may occur on instillation.
2. Be alert to allergic responses to the preservatives in the lubricants.

VII. Medications to Treat Glaucoma (Box 58.5)

A. Description
1. Some medications used to treat glaucoma reduce intraocular pressure by constricting the pupil and contracting the ciliary muscle, thereby increasing the blood flow to the retina and decreasing retinal damage and loss of vision.
2. These medications open the anterior chamber angle and increase the outflow of aqueous humor.
3. Some may be used to achieve miosis during eye surgery.
4. Contraindicated in clients with retinal detachment, adhesions between the iris and lens, or inflammatory diseases
5. Use with caution in clients with asthma, hypertension, corneal abrasion, hyperthyroidism, coronary vascular disease, urinary tract obstruction, gastrointestinal obstruction, ulcer disease, parkinsonism, and bradycardia.

Telegram & Insta: NCLEX_RN_Edu

BOX 58.5 Medications to Treat Glaucoma

Miotics
- Carbachol
- Echothiophate
- Pilocarpine hydrochloride

β-Adrenergic Blocking Eye Medications
- Betaxolol hydrochloride
- Carteolol hydrochloride
- Levobunolol hydrochloride
- Metipranolol
- Timolol maleate

α-Adrenergic Agonists
- Apraclonidine
- Brimonidine

Prostaglandin Analogs
- Bimatoprost
- Latanoprost
- Tafluprost
- Travoprost

Cholinergic Agonists
- Carbachol
- Echothiophate iodide
- Pilocarpine hydrochloride

Carbonic Anhydrase Inhibitors
- Brinzolamide
- Dorzolamide

Rho Kinase Inhibitor
- Netarsudil

B. Side effects
1. Myopia
2. Headache
3. Eye pain
4. Decreased vision in poor light
5. Local irritation

C. Adverse effects
1. Flushing
2. Diaphoresis
3. Gastrointestinal upset and diarrhea
4. Frequent urination
5. Increased salivation
6. Muscle weakness
7. Respiratory difficulty

D. Toxicity
1. Vertigo and syncope
2. Bradycardia or other dysrhythmias
3. Hypotension
4. Tremors
5. Seizures

E. Interventions
1. Assess vital signs.
2. Assess for risk of injury.
3. Assess the client for the degree of diminished vision.
4. Monitor for side and adverse effects and toxic effects.
5. Monitor for postural hypotension, and instruct the client to change positions slowly.
6. Assess breath sounds for wheezes and rhonchi, because some medications can cause bronchospasms and increased bronchial secretions.
7. Maintain oral hygiene because of the increase in salivation.
8. Have atropine sulfate available as an antidote for any cholinergic agent used to treat glaucoma.
9. Instruct the client or family regarding the correct administration of eye medications.
10. Instruct the client not to stop the medication suddenly.
11. Instruct the client to avoid activities such as driving while vision is impaired.

Instruct the client with glaucoma to read labels on over-the-counter medications and to avoid atropine-like medications, because atropine will increase intraocular pressure.

VIII. β-Adrenergic Blocker Eye Medications (see Box 58.5)

A. Description
1. These medications reduce intraocular pressure by decreasing sympathetic impulses and decreasing aqueous humor production without affecting accommodation or pupil size.
2. These medications are used to treat glaucoma.
3. These medications are contraindicated in the client with asthma or chronic obstructive pulmonary disease, because systemic absorption can cause increased airway resistance.
4. Use these medications with caution in the client receiving oral beta blockers

B. Side and adverse effects
1. Ocular irritation
2. Visual disturbances
3. Bradycardia
4. Hypotension
5. Bronchospasm

C. Interventions
1. Monitor vital signs, especially blood pressure and pulse, before administering medication.
2. Usually if the pulse is 60 beats per minute or less or if the systolic blood pressure is less than 90 mm Hg, the medication is withheld and the PHCP is contacted. The nurse should obtain pulse parameters from the PHCP for clients receiving ophthalmic beta blockers.
3. Monitor for shortness of breath.
4. Assess for risk of injury.
5. Monitor intake and output.
6. Instruct the client to notify the PHCP if shortness of breath occurs.
7. Instruct the client not to discontinue the medication abruptly.
8. Instruct the client to change positions slowly because of the potential for orthostatic hypotension.
9. Instruct the client to avoid hazardous activities.
10. Instruct the client to avoid over-the-counter medications without the PHCP's approval.
11. Instruct clients with diabetes mellitus using β-adrenergic blockers to monitor blood glucose levels frequently.

Telegram & Insta: NCLEX_RN_Edu

IX. Carbonic Anhydrase Inhibitors (see Box 58.5)

A. Description
1. Carbonic anhydrase inhibitors interfere with the production of carbonic acid, which leads to decreased aqueous humor formation and decreased intraocular pressure.
2. These medications are used for the long-term treatment of glaucoma.
3. These medications are contraindicated in the client allergic to sulfonamides.
4. Use with caution for clients with severe renal or liver disease.

B. Side and adverse effects
1. Appetite loss
2. Gastrointestinal upset
3. Paresthesias in the fingers, toes, and face
4. Polyuria
5. Hypokalemia
6. Renal calculi
7. Photosensitivity
8. Lethargy and drowsiness
9. Depression

C. Interventions
1. Monitor vital signs.
2. Assess visual acuity.
3. Assess for risk of injury.
4. Monitor intake and output.
5. Monitor weight.
6. Maintain oral hygiene.
7. Monitor for side effects such as lethargy, anorexia, drowsiness, polyuria, nausea, and vomiting.
8. Monitor electrolyte levels for hypokalemia.
9. Increase fluid intake unless contraindicated.
10. Advise the client to avoid prolonged exposure to sunlight.
11. Encourage the use of artificial tears for dry eyes.
12. Instruct the client not to discontinue the medication abruptly.
13. Instruct the client to avoid hazardous activities while vision is impaired.
14. Teach the client not to wear contact lenses during or within 15 minutes of instilling these medications.

X. Ocusert System

A. Description
1. A thin eye wafer (disk) is impregnated with a time-release dose of pilocarpine.
2. The Ocusert system was devised to overcome the need for frequent instillation of pilocarpine.
3. It is placed in the upper or lower cul-de-sac of the eye.
4. The pilocarpine is released over 1 week.
5. The disk is replaced every 7 days.
6. Drawbacks of its use include sudden leakage of pilocarpine, migration of the system over the cornea, and unnoticed loss of the system.

B. Interventions
1. Assess the client's ability to insert the medication disk.
2. Store the medication in the refrigerator.
3. Instruct the client to discard damaged or contaminated disks.
4. Inform the client that temporary stinging is expected but to notify the PHCP if blurred vision or brow pain occurs.
5. Instruct the client to check for the presence of the disk in the upper or lower cul-de-sac daily at bedtime and on arising.
6. Because vision may change in the first few hours after the eye system is inserted, instruct the client to replace the disk at bedtime.

XI. Osmotic Medications

A. Description
1. Osmotic medications lower intraocular pressure; an example is mannitol.
2. They are used in emergency treatment of glaucoma and are used preoperatively and postoperatively to decrease vitreous humor volume.

B. Side and adverse effects
1. Headache
2. Nausea, vomiting, diarrhea, dehydration
3. Disorientation
4. Electrolyte imbalances

C. Interventions
1. Assess vital signs.
2. Assess visual acuity.
3. Assess for risk of injury.
4. Monitor intake and output.
5. Monitor weight.
6. Monitor for electrolyte imbalances.
7. Increase fluid intake unless contraindicated.
8. Monitor for changes in level of orientation.

XII. Medications to Treat Macular Degeneration

A. Pegaptanib, ranibizumab, bevacizumab, aflibercept, verteporfin

B. Description
1. Age-related **macular degeneration** (ARMD) can be dry ARMD (atrophic) or wet ARMD (neovascular).
2. Dry ARMD is more common; macular photoreceptors undergo gradual breakdown, leading to gradual blurring of central vision.
3. Wet ARMD progresses faster, and macular degeneration is caused by the growth of new subretinal blood vessels, which leads to fluid leakage that lifts the macula and causes permanent injury.
4. Characterized by the presence of drusen (yellow deposits under the retina).

C. Side and adverse effects
1. Endophthalmitis (eye inflammation caused by bacterial, viral, or fungal infection)

Telegram & Insta: NCLEX_RN_Edu

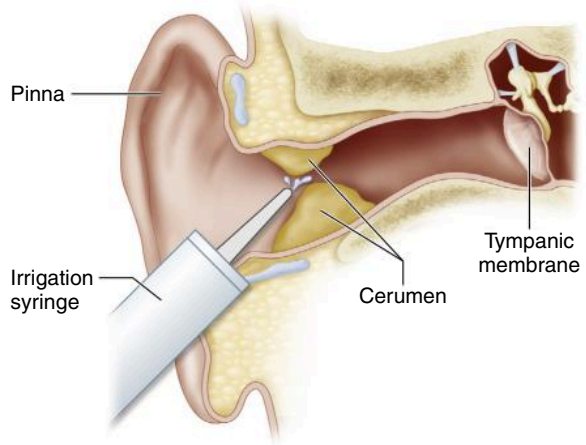

FIG. 58.2 Irrigation of the external canal. Cerumen and debris can be removed from the ear by irrigation with warm water. The stream of water is aimed above or below the impaction to allow back pressure to push it out rather than farther down the canal.

2. Blurred vision
3. Cataracts
4. Corneal edema
5. Eye discomfort and discharge
6. Conjunctival hemorrhage
7. Increased intraocular pressure
8. Reduced visual acuity

D. Interventions
1. Teach the client about administration of the medications.
2. Teach the client about side effects and when to notify the PHCP.

XIII. Otic Medication Administration

A. Instillation of ear drops
1. In an adult, pull the pinna up and back to straighten the external canal to instill ear drops.
2. Tilt the client's head in the opposite direction of the affected ear, and apply the drops into the ear.
3. With the head tilted, gently move the head back and forth 5 times.
4. Pull the pinna down and back for infants and children younger than 3 years, up and back for older children.

B. Irrigation of the ear (Fig. 58.2)
1. Irrigation of the ear needs to be prescribed by the PHCP.
2. Ensure direct visualization of the tympanic membrane.
3. Warm the irrigating solution to 98.6° F (37.0° C), because a solution temperature that is not close to the client's body temperature will cause ear injury, nausea, vertigo, and nystagmus.
4. Irrigation must be done gently to avoid damage to the eardrum.
5. When irrigating, to prevent injury, do not direct irrigation solution directly toward the eardrum but rather toward the wall of the ear canal. In addition, to remove cerumen, the solution is directed above or below the impaction toward the wall of the canal to allow back pressure to push the impaction out.
6. During irrigation, the client should be positioned with the ear to be irrigated facing up. Fall precautions should be instituted, because the client may get dizzy, and an emesis basin should be available, because vomiting can occur.

C. Systemic medications that affect hearing (Box 58.6)

If a perforation of the eardrum is suspected, do not perform ear irrigation.

BOX 58.6 Medications That Affect Hearing

Antibiotics
- Amikacin
- Chloramphenicol
- Erythromycin
- Gentamicin
- Neomycin
- Streptomycin sulfate
- Tetracycline
- Tobramycin sulfate
- Vancomycin

Diuretics
- Ethacrynic acid
- Furosemide

Others
- Amitriptyline
- Aspirin
- Bleomycin
- Chloroquine
- Cisplatin
- Ibuprofen
- Naproxen
- Nitrogen mustard
- Quinine
- Quinidine
- Sildenafil

BOX 58.7 Antiinfective Ear Medications

- Acetic acid; aluminum acetate
- Amoxicillin
- Ampicillin
- Cefaclor
- Chloramphenicol
- Ciprofloxacin
- Clarithromycin
- Clindamycin hydrochloride
- Erythromycin
- Gentamicin sulfate otic solution
- Ofloxacin
- Penicillin V potassium
- Trimethoprim; sulfamethoxazole

XIV. Antiinfective Ear Medications (Box 58.7)

A. Description
1. Antiinfective medications kill or inhibit the growth of bacteria and are used for otitis media or otitis externa.
2. These medications are contraindicated if a prior hypersensitivity exists.

B. Side and adverse effect: Overgrowth of nonsusceptible organisms

C. Interventions
1. Monitor vital signs.
2. Assess for allergies.
3. Assess for pain.
4. Monitor for signs of secondary infection.
5. Instruct the client to report dizziness, fatigue, fever, or sore throat, which may indicate a superimposed infection.

Telegram & Insta: NCLEX_RN_Edu

BOX 58.8 Antihistamines and Decongestants

- Brompheniramine
- Cetirizine
- Chlorpheniramine
- Diphenhydramine
- Fexofenadine
- Loratadine
- Levocetirizine
- Phenylephrine
- Pseudoephedrine

6. Instruct the client to complete the entire course of the medication.
7. Instruct the client to keep ear canals dry.

XV. Antihistamines and Decongestants (Box 58.8)

A. Description
1. These medications stimulate the receptors of the respiratory mucosa.
2. These medications reduce respiratory tissue hyperemia and edema to open obstructed eustachian tubes.
3. May be used for acute otitis media
4. Antihistamines and decongestants do not have the same mechanism of action but they produce similar results.
5. Antihistamines suppress the histamine response, which suppresses vasodilation, and are typically indicated for nasal congestion due to an allergic response, whereas decongestants are for generalized nasal congestion, regardless of cause.

B. Side and adverse effects
1. Drowsiness
2. Blurred vision
3. Dry mucous membranes

C. Interventions
1. Inform the client that drowsiness, blurred vision, and a dry mouth may occur.
2. Instruct the client to increase fluid intake unless contraindicated and to suck on hard candy to alleviate the dry mouth.
3. Instruct the client to avoid hazardous activities if drowsiness occurs.
4. Instruct the client with hypertension to consult the PHCP prior to the use of these medications.

XVI. Ceruminolytic Medication

A. Carbamide peroxide

B. Description
1. Emulsifies and loosens cerumen deposits
2. Used to loosen and remove impacted wax from the ear canal

C. Side and adverse effects
1. Irritation
2. Redness or swelling of the ear canal

D. Interventions
1. Instruct the client not to use drops more often than prescribed.
2. Moisten a cotton plug with medication and insert the cotton plug after instilling the ear drops.
3. Keep the container tightly closed and away from moisture.
4. Avoid touching the ear with the dropper.
5. Thirty minutes after instillation, gently irrigate the ear as prescribed with warm water, using a soft rubber bulb ear syringe.
6. Irrigation may be done with hydrogen peroxide solution as prescribed to flush cerumen deposits out of the ear canal.
7. For a chronic cerumen impaction, 1 or 2 drops of mineral oil (if prescribed) will soften the wax.
8. Instruct the client to notify the PHCP if redness, pain, or swelling persists.

PRACTICE QUESTIONS

1. Betaxolol hydrochloride eye drops have been prescribed for a client with glaucoma. Which nursing action is **most appropriate** related to monitoring for side and adverse effects of this medication?
1. Assessing for edema
2. Monitoring temperature
3. Monitoring blood pressure
4. Assessing blood glucose level

2. The nurse is preparing to administer eye drops to a client being prepared for cataract surgery. Which actions would the nurse take to administer the drops? **Select all that apply.**
- ❑ 1. Wash hands.
- ❑ 2. Put gloves on.
- ❑ 3. Place the drop in the conjunctival sac.
- ❑ 4. Pull the lower lid down against the cheekbone.
- ❑ 5. Instruct the client to squeeze the eyes shut after instilling the eye drop.
- ❑ 6. Instruct the client to tilt the head forward, open the eyes, and look down.

3. The nurse prepares a client for ear irrigation as prescribed by the primary health care provider. Which action would the nurse take when performing the procedure?
1. Warm the irrigating solution to 98.6° F (37.0° C).
2. Position the client with the affected side up following the irrigation.
3. Direct a slow, steady stream of irrigation solution toward the eardrum.
4. Assist the client to turn their head so that the ear to be irrigated is facing upward.

4. The nurse is providing instructions to a client who will be self-administering eye drops. To minimize systemic absorption of the eye drops, the nurse would instruct the client to take which action?
1. Eat before instilling the drops.

Telegram & Insta: NCLEX_RN_Edu

2. Swallow several times after instilling the drops.
3. Blink vigorously to encourage tearing after instilling the drops.
4. Occlude the nasolacrimal duct with a finger after instilling the drops.

5. A client is prescribed an eye drop and an eye ointment for the right eye. How would the nurse **best** administer the medications?
1. Administer the eye drop first, followed by the eye ointment.
2. Administer the eye ointment first, followed by the eye drop.
3. Administer the eye drop, wait 20 minutes, and administer the eye ointment.
4. Administer the eye ointment, wait 20 minutes, and administer the eye drop.

6. Which medication, if prescribed for the client with glaucoma, would the nurse question?
1. Betaxolol
2. Pilocarpine
3. Erythromycin
4. Atropine sulfate

7. A miotic medication has been prescribed for the client with glaucoma, and the client asks the nurse about the purpose of the medication. Which response would the nurse provide to the client?
1. "The medication will help dilate the eye to prevent pressure from occurring."
2. "The medication will relax the muscles of the eyes and prevent blurred vision."
3. "The medication causes the pupil to constrict and will lower the pressure in the eye."
4. "The medication will help block the responses that are sent to the muscles in the eye."

8. A client was just admitted to the hospital to rule out a gastrointestinal (GI) bleed. The client has brought several bottles of medications prescribed by different specialists. During the admission assessment, the client states, "Lately, I have been hearing some noisy sounds in my ears, especially when I am alone." Which medication would the nurse identify as the cause of the client's complaint?
1. Doxycycline
2. Atropine sulfate
3. Acetylsalicylic acid
4. Diltiazem hydrochloride

9. In preparation for cataract surgery, the nurse is to administer cyclopentolate eye drops at 0900 for surgery that is scheduled for 0915. What **initial** action would the nurse take in relation to the characteristics of the medication action?
1. Provide lubrication to the operative eye prior to giving the eye drops.
2. Call the surgeon, as this medication will further constrict the operative pupil.
3. Consult the surgeon, as there is not sufficient time for the dilative effects to occur.
4. Give the medication as prescribed; the surgeon needs optimal constriction of the pupil.

ANSWERS

1. *Answer:* 3
Rationale: Hypotension, dizziness, nausea, diaphoresis, headache, fatigue, constipation, and diarrhea are side and adverse effects of the medication. Nursing interventions include monitoring the blood pressure for hypotension and assessing the pulse for strength, weakness, irregular rate, and bradycardia. Options 1, 2, and 4 are not specifically associated with this medication.
Test-Taking Strategy: Note the strategic words, *most appropriate*. Use the ABCs—airway, breathing, and circulation—to direct you to the correct option.
References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed). St. Louis: Elsevier. pp. 1274-1275; Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 371.

2. *Answer:* 1, 2, 3, 4
Rationale: To administer eye medications, the nurse would wash hands and put gloves on. The client is instructed to tilt the head backward, open the eyes, and look up. The nurse pulls the lower lid down against the cheekbone and holds the bottle like a pencil with the tip downward. Holding the bottle, the nurse gently rests the wrist of the hand on the client's cheek and squeezes the bottle gently to allow the drop to fall into the conjunctival sac. The client is instructed to close the eyes gently and not to squeeze the eyes shut to prevent the loss of medication.
Test-Taking Strategy: Focus on the subject, the procedure for administering eye drops. Use guidelines related to standard precautions and visualize this procedure. This will assist in determining the correct interventions.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 103, 127.

3. *Answer:* 1
Rationale: Before ear irrigation, the nurse would inspect the tympanic membrane to ensure that it is intact. The irrigating solution needs to be warmed to 98.6° F (37.0° C), because a solution temperature that is not close to the client's body temperature will cause ear injury, nausea, and vertigo. The nurse would check the temperature of the solution on the inner forearm. The affected side needs to be down following the irrigation to assist in drainage of the fluid. When irrigating, a

Telegram & Insta: NCLEX_RN_Edu

direct and slow steady stream of irrigation solution is directed toward the wall of the canal, not toward the eardrum. The client is positioned sitting, facing forward with the head in a natural position; if the ear is faced upward, the nurse would not be able to visualize the canal.
Test-Taking Strategy: Focus on the **subject,** the procedure for performing ear irrigation. Think about the purpose of this procedure and keep safety in mind. Visualizing each step and the information in the options will assist in eliminating the incorrect ones.
Reference: Sweet, V., & Foley, P. (Editors). (2020). *Sheehy's emergency nursing: Principles and practice.* (7th ed.). St. Louis: Elsevier. pp. 359-360.

4. *Answer:* 4
Rationale: Applying pressure on the nasolacrimal duct prevents systemic absorption of the medication. Options 1, 2, and 3 will not prevent systemic absorption.
Test-Taking Strategy: Focus on the **subject,** systemic effects. Eating and swallowing are **comparable or alike** and are not related to the systemic absorption of eye drops. Blinking vigorously to produce tearing may result in the loss of the administered medication.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 127-128.

5. *Answer:* 1
Rationale: When an eye drop and an eye ointment are scheduled to be administered at the same time, the eye drop is administered first. The instillation of two medications is separated by 5 to 10 minutes.
Test-Taking Strategy: Note the **strategic word,** *best*. Focus on the **subject,** the guidelines for administering eye medications. Eliminate options 3 and 4 first because of the words *20 minutes*. Next, thinking about the consistency and absorption of a drop versus ointment will direct you to the correct option.
References: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. p.127; Sweet, V., & Foley, P. (Editors), (2020). *Sheehy's emergency nursing: Principles and practice.* (7th ed.). St. Louis: Elsevier. p. 368.

6. *Answer:* 4
Rationale: Options 1 and 2 are miotic agents used to treat glaucoma. Option 3 is an antiinfective medication used to treat bacterial conjunctivitis. Atropine sulfate is a mydriatic and cycloplegic (also anticholinergic) medication, and its use is contraindicated in clients with glaucoma. Mydriatic medications dilate the pupil and can cause an increase in intraocular pressure in the eye.
Test-Taking Strategy: Focus on the **subject,** the medication that the nurse would question. Recalling the classifications of the medications identified in the options will assist in answering the question. Remember that mydriatics dilate the pupil and that these medications are contraindicated in glaucoma.
References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 124, 1273; Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 116.

7. *Answer:* 3
Rationale: Miotics cause pupillary constriction and are used to treat glaucoma. They lower the intraocular pressure, thereby increasing blood flow to the retina and decreasing retinal damage and loss of vision. Miotics cause a contraction of the ciliary muscle and a widening of the trabecular meshwork. Options 1, 2, and 4 are incorrect.
Test-Taking Strategy: Note that the client has glaucoma. Recall that prevention of increased intraocular pressure is the goal in the client with glaucoma. Options 1, 2, and 4 are **comparable or alike** and describe actions related to mydriatic medications, which primarily dilate the pupils and relax the ciliary muscles.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 879, 884-885.

8. *Answer:* 3
Rationale: Aspirin (acetylsalicylic acid) is contraindicated for GI bleeding and is potentially ototoxic. The client needs to be advised to notify the prescribing primary health care provider so that the medication can be discontinued and/or a substitute that is less toxic to the ear can be taken instead. Options 1, 2, and 4 do not have effects that are potentially associated with hearing difficulties.
Test-Taking Strategy: Focus on the **subject,** the medication that may be causing the client's complaint. Review the classifications and/or therapeutic effects as well as the side and adverse effects of each medication in the options. Of the medications identified, only aspirin can cause ototoxicity. In addition, it is contraindicated for GI bleed.
References: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 681-682; Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 102-103.

9. *Answer:* 3
Rationale: Cyclopentolate is a rapidly acting mydriatic and cycloplegic medication. Cyclopentolate is effective in 25 to 75 minutes, and accommodation returns in 6 to 24 hours. Cyclopentolate is used for preoperative mydriasis, not pupil constriction. The nurse would consult with the surgeon about the time of administration of the eye drops, because 15 minutes is not adequate time for dilation to occur.
Test-Taking Strategy: Note the **strategic word**, *initial*. Options 2 and 4 are **comparable or alike** and are eliminated first (*miosis* refers to a constricted pupil). Note that the question identifies a client being prepared for eye surgery. The pupil would need to be dilated for the surgical procedure.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 895-896.

UNIT XV

Neurological Problems of the Adult Client

Pyramid to Success

Pyramid Points related to neurological disorders focus on nursing care and monitoring for increased intracranial pressure, assessing level of consciousness, positioning clients safely, head injuries, spinal cord injuries, spinal shock, autonomic dysreflexia, interventions during a seizure, stroke, Parkinson's disease, and myasthenia gravis. The points related to the psychosocial effects of the neurological disorder, such as anxiety, unexpected body image changes, and the appropriate and available support services needed for the client are emphasized.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Acting as a client advocate
Collaborating with the interprofessional health care team
Ensuring that advance directives are in place as appropriate
Initiating referrals to appropriate services
Maintaining asepsis with procedures and treatments
Maintaining confidentiality
Maintaining standard and other precautions
Obtaining informed consent for invasive procedures
Preventing accidents that can occur as a result of neurological deficits
Prioritizing hypotheses based on client needs
Upholding client rights

Health Promotion and Maintenance

Generating solutions for maintaining independence in self-care activities
Performing neurological assessment using various techniques
Preventing and detecting health problems associated with neurological deficits
Providing home care instructions regarding care related to the neurological disorder
Recognizing cues that indicate risk factors for a neurological injury
Teaching about the importance of prescribed therapy

Psychosocial Integrity

Addressing grief and loss issues
Assessing the ability to cope with feelings of isolation and loss of independence
Considering the cultural, religious, and spiritual influences of the client when planning care
Discussing expected and unexpected body image changes resulting from neurological deficits
Identifying sensory and perceptual alterations
Identifying support systems and encouraging the use of community resources
Mobilizing coping mechanisms

Physiological Integrity

Administering pharmacological therapy
Analyzing assessment data to determine the client's status
Evaluating outcomes in the plan of care
Maintaining nutrition
Monitoring for alterations in body systems
Monitoring for complications related to procedures
Monitoring for fluid and electrolyte imbalances
Promoting normal elimination patterns
Promoting self-care measures
Providing assistive devices for performing activities of daily living
Providing measures to promote comfort
Recognizing cues that indicate a complication
Taking action in emergency situations

CHAPTER 59

Neurological Problems

Contributor: David Petersen, MSN-Ed, RN

PRIORITY CONCEPTS **Functional Ability; Intracranial Regulation**

I. Anatomy and Physiology of the Brain and Spinal Cord

A. Cerebrum
- **1.** The cerebrum consists of the right and left hemispheres.
- **2.** Each hemisphere receives sensory information from the opposite side of the body and controls the skeletal muscles of the opposite side.
- **3.** The cerebrum governs sensory and motor activity and thought and learning.

B. Cerebral cortex (Box 59.1)
- **1.** The cerebral cortex is the outer gray layer; it is divided into five lobes.
- **2.** It is responsible for the conscious activities of the cerebrum.

C. Basal ganglia: Cell bodies in white matter that help the cerebral cortex produce smooth voluntary movements

D. Diencephalon
- **1.** Thalamus
  - **a.** Relays sensory impulses to the cortex
  - **b.** Provides a pain gate
  - **c.** Part of the reticular activating system
- **2.** Hypothalamus
  - **a.** Regulates autonomic responses of the sympathetic and parasympathetic nervous systems
  - **b.** Regulates the stress response, sleep, appetite, body temperature, fluid balance, and emotions
  - **c.** Responsible for the production of hormones secreted by the pituitary gland and the hypothalamus

E. Brainstem
- **1.** Midbrain
  - **a.** Responsible for motor coordination
  - **b.** Contains the visual reflex and auditory relay centers
- **2.** Pons: Contains the respiratory centers and regulates breathing
- **3.** Medulla oblongata
  - **a.** Contains all afferent and efferent tracts and cardiac, respiratory, vomiting, and vasomotor centers
  - **b.** Controls heart rate, respiration, blood vessel diameter, sneezing, swallowing, vomiting, and coughing

F. Cerebellum: Coordinates muscle movement, posture, equilibrium, and muscle tone

G. Spinal cord
- **1.** Provides neuron and synapse networks to produce involuntary responses to sensory stimulation
- **2.** Controls body movement and regulates visceral function
- **3.** Carries sensory information to and motor information from the brain
- **4.** Extends from the first cervical to the second lumbar vertebra
- **5.** Protected by the meninges, cerebrospinal fluid (CSF), and adipose tissue
- **6.** Horns
  - **a.** Inner column of gray matter; contains two anterior and two posterior horns
  - **b.** Posterior horns connect with afferent (sensory) nerve fibers.
  - **c.** Anterior horns contain efferent (motor) nerve fibers.
- **7.** Nerve tracts
  - **a.** White matter contains the nerve tracts.
  - **b.** Ascending tracts (sensory pathway)
  - **c.** Descending tracts (motor pathway)

H. Meninges
- **1.** The dura mater is a tough and fibrous membrane.

Telegram & Insta: NCLEX_RN_Edu

BOX 59.1 Cerebral Cortex

Frontal Lobe
- Broca's area for production of speech
- Morals, emotions, reasoning and judgment, concentration, abstraction, and memory retention

Parietal Lobe
- Interpretation of taste, pain, touch, temperature, and pressure
- Spatial perception

Temporal Lobe
- Auditory center
- Wernicke's area for comprehension of speech

Occipital Lobe
- Visual area

Limbic System
- Emotional and visceral patterns for survival
- Learning and memory
- Also regulates sexual response

2. The arachnoid membrane is a delicate membrane and contains CSF.
3. The pia mater is a vascular membrane.
4. The subarachnoid space is formed by the arachnoid membrane and the pia mater.

I. CSF
1. Secreted in the ventricles; circulates in the subarachnoid space and through the ventricles to the subarachnoid space of the meninges, where it is reabsorbed
2. Acts as a protective cushion; aids in the exchange of nutrients and wastes
3. Normal pressure is 6 to 25 cm H_2O.
4. Normal volume is 125 to 150 mL.
5. About 500 mL/day is produced

J. Ventricles
1. Four ventricles
2. The ventricles communicate between the subarachnoid spaces and produce and circulate CSF.

K. Blood supply
1. Right and left internal carotid arteries
2. Right and left vertebral arteries
3. These arteries supply the brain via an anastomosis at the base of the brain called the *circle of Willis.*

L. Neurotransmitters
1. Acetylcholine
2. Epinephrine
3. Norepinephrine
4. Dopamine
5. Serotonin
6. γ-aminobutyric acid (GABA)

M. Neurons
1. The neuron consists of the cell body, axon, and dendrites.
2. The cell body contains the nucleus.
3. Neurons carrying impulses from the peripheral nervous system to the central nervous system (CNS) are called *sensory neurons.*
4. Neurons carrying impulses away from the CNS are called *motor neurons.*
5. Synapse is the chemical transmission of impulses from one neuron to another.

N. Axons and dendrites
1. The axon conducts impulses from the cell body.
2. The dendrites receive stimuli from the body and transmit them to the axon.
3. The neurons are protected and insulated by Schwann cells.
4. The Schwann cell sheath is called the *neurolemma.*
5. Neurons do not reproduce after the neonatal period.
6. If an axon or dendrite is damaged, it will die and be replaced slowly only if the neurolemma is intact and the cell body has not died.

O. Spinal nerves
1. Afferent (sensory) nerve fibers and efferent (motor) nerve fibers combine to form 31 pairs of spinal nerves.
2. Mixed nerve fibers are formed by the joining of the anterior motor and posterior sensory roots.

P. Autonomic nervous system (involuntary functions)
1. Sympathetic (adrenergic) fibers dilate pupils, increase heart rate and rhythm, contract blood vessels, and relax smooth muscles of the bronchi. Norepinephrine is a major neurotransmitter for the sympathetic nervous system.
2. Parasympathetic (cholinergic) fibers produce the opposite effect. Acetylcholine is a major parasympathetic nervous system transmitter that contracts smooth muscles, dilates blood vessels, increases bodily secretions, and slows heart rate.

II. Diagnostic Tests

A. Skull and spinal radiography
1. Description
   a. Radiographs of the skull reveal the size and shape of the skull bones, suture separation in infants, fractures or bony defects, erosion, and calcification.
   b. Spinal radiographs identify fractures, dislocation, compression, curvature, erosion, narrowed spinal cord, and degenerative processes.
2. Preprocedure interventions
   a. Provide nursing support for the confused, combative, or ventilator-dependent client.
   b. Maintain immobilization of the neck if a spinal fracture is suspected.
   c. Remove metal items from the client.
   d. If the client has thick and heavy hair, this should be documented because it could affect interpretation of the x-ray film.

Telegram & Insta: NCLEX_RN_Edu

3. Postprocedure intervention: Maintain immobilization until results are known.

⚠ Always check with the client about the possibility of pregnancy before any radiographic procedures.

B. Computed tomography (CT)

1. Description
   - **a.** A type of brain scanning that may or may not require injection of a dye.
   - **b.** It is used to detect intracranial bleeding, space-occupying lesions, cerebral edema, infarctions, hydrocephalus, cerebral atrophy, and shifts of brain structures.

⚠ An informed consent is needed for any invasive procedure, including those that use a contrast medium (dye).

2. Preprocedure interventions
   - **a.** Assess for allergies to iodine, contrast dyes, or shellfish if a dye is used.
   - **b.** Assess renal function and verify contrast dose with the pharmacy.
   - **c.** Instruct the client of the need to lie still and flat during the test.
   - **d.** Instruct the client to hold their breath when requested.
   - **e.** Initiate an intravenous line with the appropriate gauge size if prescribed.
   - **f.** Remove objects from the head, such as wigs, barrettes, earrings, and hairpins.
   - **g.** Assess for claustrophobia.
   - **h.** Inform the client of possible mechanical noises as the scanning occurs.
   - **i.** Inform the client that there may be a hot, flushed sensation and a metallic taste in the mouth when the dye is injected.
   - **j.** Note that some clients may be given the dye even if they report an allergy; they may be treated with an antihistamine and corticosteroids before the injection to reduce the severity of a reaction.

⚠ Assess the need to withhold metformin on the day of the test if iodinated contrast dye is used for a diagnostic procedure because of the risk for metformin-induced lactic acidosis.

3. Postprocedure interventions
   - **a.** Provide replacement fluids, because diuresis from the dye is expected.
   - **b.** Monitor for an allergic reaction to the dye.
   - **c.** Assess the dye injection site for bleeding or hematoma, and monitor the extremity for color, warmth, and the presence of distal pulses.

C. Magnetic resonance imaging (MRI)

1. Description
   - **a.** A noninvasive procedure that identifies tissues, tumors, and vascular abnormalities
   - **b.** It is similar to CT scanning but provides more detailed pictures.
2. Preprocedure interventions
   - **a.** Remove all metal objects from the client.
   - **b.** Determine whether the client has a pacemaker, implanted defibrillator, or other metal appliances such as a hip prosthesis or vascular clips, because these clients cannot have this test performed.
   - **c.** Insert an intermittent infusion device (saline lock) on all intravenous accesses prior to the procedure (intravenous fluid pumps are not allowed in the MRI room).
   - **d.** Provide precautions for the client who is attached to a pulse oximeter, because it can cause a burn during testing if coiled around the body or a body part.
   - **e.** Provide an assessment of the client with claustrophobia (may not be necessary if an open MRI machine is used).
   - **f.** Administer medication as prescribed for the client with claustrophobia.
   - **g.** Determine whether a contrast agent is to be used, and follow the prescription related to the administration of food, fluids, and medications. Verify allergies and renal function prior to administration.
   - **h.** Instruct clients that they will need to remain still during the procedure.
3. Postprocedure interventions
   - **a.** The client may resume normal activities.
   - **b.** Increase fluid intake and expect diuresis if a contrast agent is used.

D. Lumbar puncture

1. Description
   - **a.** Insertion of a spinal needle through the L3–L4 interspace into the lumbar subarachnoid space to obtain CSF; measure CSF fluid or pressure; or instill air, dye, or medications.
   - **b.** The test is contraindicated in clients with **increased intracranial pressure (ICP)**, because the procedure will cause a rapid decrease in pressure in the CSF around the spinal cord, leading to brain herniation.
2. Preprocedure interventions: Have the client empty the bladder, provide appropriate client education, and review coagulation studies/platelet count to assess for risk of bleeding.
3. Interventions during the procedure
   - **a.** Position the client in a lateral recumbent position and have the client draw the knees up to the abdomen and the chin onto the chest; the prone position may be required for radiologically guided punctures.

Telegram & Insta: NCLEX_RN_Edu

b. Assist with the collection of specimens (label the specimens in sequence).
c. Maintain strict asepsis.
d. Assess for dizziness.

4. Postprocedure interventions
a. Monitor vital signs and neurological signs to check for the presence of leakage of CSF and also monitor for headache.
b. Position the client flat as prescribed.
c. Encourage fluids to replace CSF obtained from the specimen collection or from leakage.
d. Monitor intake and output.

E. Cerebral angiography
1. Description: Injection of a contrast material, usually through the femoral artery (or another artery) into the carotid arteries to visualize the cerebral arteries and assess for lesions
2. Preprocedure interventions
a. Assess the client for allergies to iodine and shellfish.
b. Assess renal function.
c. Assess for a medication history of anticoagulation therapy; withhold the anticoagulant medication prior to the procedure as prescribed.
d. Encourage hydration for 2 days before the test.
e. Maintain the client on NPO (nothing by mouth) status 4 to 6 hours before the test as prescribed.
f. Perform a neurological assessment, which will serve as a baseline for postprocedure assessments.
g. Mark the peripheral pulses.
h. Remove metal items from the hair.
i. Administer premedication as prescribed.
3. Postprocedure interventions
a. Monitor neurological status, vital signs, signs of bleeding, and neurovascular status of the affected extremity frequently until stable.
b. Monitor for swelling in the neck and for difficulty swallowing; notify a primary health care provider (PHCP) if these symptoms occur.
c. Maintain bed rest for 12 hours as prescribed.
d. Elevate the head of the bed 15 to 30 degrees only if prescribed.
e. Keep the bed flat, as prescribed, if the femoral artery is used.
f. Assess peripheral pulses.
g. Apply sandbags or another device to immobilize the limb and a pressure dressing to the injection site to decrease bleeding as prescribed.
h. Place ice on the puncture site as prescribed.
i. Encourage fluid intake.

F. Electroencephalography
1. Description: Noninvasive, graphic recording of the electrical activity of the superficial layers of the cerebral cortex
2. Preprocedure interventions
a. Wash the client's hair.
b. Inform the client that electrodes are attached to the head and that electricity does not enter the head.
c. Withhold stimulants such as coffee, tea, and caffeine beverages; antidepressants; tranquilizers; and possibly antiseizure medications for 24 to 48 hours before the test as prescribed.
d. Allow the client to have breakfast if prescribed.
e. Premedicate for sedation as prescribed.
3. Postprocedure interventions
a. Wash the client's hair.
b. Maintain safety precautions if the client was sedated.

G. Caloric testing (oculovestibular reflex)
1. Description: Caloric testing provides information about the function of the vestibular portion of cranial nerve VIII and aids in the diagnosis of cerebellar and brainstem lesions.
2. Procedure
a. Patency of the external auditory canal is confirmed.
b. The client is positioned supine with the head of the bed elevated 30 degrees.
c. Water that is warmer or cooler than body temperature is infused into the ear.
d. A normal response is the onset of vertigo and nystagmus (involuntary eye movements) within 20 to 30 seconds.
e. Absent or disconjugate eye movements indicate brainstem damage.

III. Neurological Assessment (see Chapter 12 for additional information on neurological assessment)

A. Assessment of risk factors
1. Trauma
2. Hemorrhage
3. Tumors
4. Infection
5. Toxicity
6. Metabolic disorders
7. Hypoxic conditions
8. Hypertension
9. Cigarette smoking
10. Stress
11. Aging process
12. Chemicals, either ingestion or environmental exposure

B. Assessment of cranial nerves (see Chapter 12)
C. Assessment of level of consciousness (LOC) (see Chapter 12)

Telegram & Insta: NCLEX_RN_Edu

BOX 59.2 Assessment of Respirations

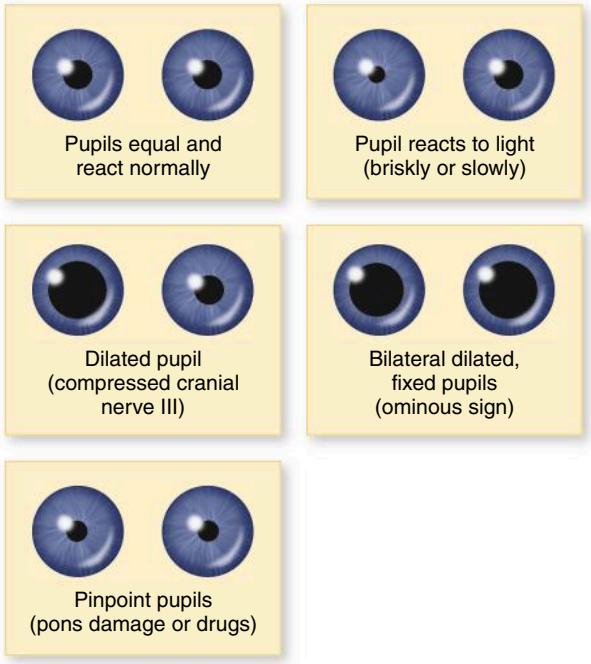
Cheyne-Stokes
- Rhythmic, with periods of apnea
- Can indicate a metabolic dysfunction or dysfunction in the cerebral hemisphere or basal ganglia

Neurogenic Hyperventilation
- Regular rapid and deep sustained respirations
- Indicates a dysfunction in the low midbrain and middle pons

Apneustic
- Irregular respirations, with pauses at the end of inspiration and expiration
- Indicates a dysfunction in the middle or caudal pons

Ataxic
- Totally irregular in rhythm and depth
- Indicates a dysfunction in the medulla

Cluster
- Clusters of breaths with irregularly spaced pauses
- Indicates a dysfunction in the medulla and pons



Pupils equal and react normally
Pupil reacts to light (briskly or slowly)
Dilated pupil (compressed cranial nerve III)
Bilateral dilated, fixed pupils (ominous sign)
Pinpoint pupils (pons damage or drugs)

FIG. 59.1 Pupillary check for size and response.

D. Assessment of vital signs: Monitor for **blood pressure** or pulse changes, which may indicate increased ICP.

E. Assessment of respirations (Box 59.2)

⚠ Level of consciousness is the most sensitive indicator of neurological status.

F. Assessment of temperature
1. An elevated temperature increases the metabolic rate of the brain.
2. An elevation in temperature may indicate a dysfunction of the hypothalamus or brainstem.
3. A slow rise in temperature may indicate infection.

G. Assessment of pupils (Fig. 59.1)
1. Unilateral pupil dilation indicates compression of cranial nerve III.
2. Midposition fixed pupils indicate midbrain injury.
3. Pinpoint fixed pupils indicate pontine damage.

H. Assessment for posturing (see Chapter 39, Fig. 39.3)
1. Posturing indicates a deterioration of the condition.
2. Flexor (**decorticate posturing**)
   - **a.** Client flexes one or both arms on the chest and may extend the legs stiffly.
   - **b.** Flexor posturing indicates a nonfunctioning cortex.
3. Extensor (**decerebrate posturing**)
   - **a.** Client stiffly extends one or both arms and possibly the legs.
   - **b.** Extensor posturing indicates a brainstem lesion.

BOX 59.3 Assessment of Reflexes

Babinski's Reflex
- Dorsiflexion of the big toe and fanning of the other toes; elicited by firmly stroking the lateral aspect of the sole of the foot
- Is a pathological or abnormal reflex in anyone older than 2 years and represents the presence of central nervous system (CNS) disease

Corneal (Blink) Reflex
- Involuntary closure of the eyelids in response to stimulation of the cornea
- Loss of the blink reflex indicates a dysfunction of cranial nerve V.

Gag Reflex
- Contraction of pharyngeal muscle, elicited by touching the back of the throat
- Loss of the gag reflex indicates a dysfunction of cranial nerves IX and X.

4. **Flaccid posturing**: Client displays no motor response in any extremity.

I. Assessment of reflexes (Box 59.3)

J. Assessment of meningeal irritation (Box 59.4)

K. Assessment of the autonomic system
1. Sympathetic functions, adrenergic responses
   - **a.** Increased pulse and blood pressure
   - **b.** Dilated pupils
   - **c.** Decreased peristalsis
   - **d.** Increased perspiration

Telegram & Insta: NCLEX_RN_Edu

BOX 59.4 Assessment of Meningeal Irritation

General Findings
- Irritability
- Nuchal rigidity
- Severe, unrelenting headaches
- Generalized muscle aches and pains
- Nausea and vomiting
- Fever and chills
- Tachycardia
- Photophobia
- Nystagmus
- Abnormal pupil reaction and eye movement

Brudzinski's Sign
- Involuntary flexion of the hip and knee when the neck is passively flexed; indicates meningeal irritation

Kernig's Sign
- Loss of the ability of a supine client to straighten the leg completely when it is fully flexed at the knee and hip; indicates meningeal irritation

Motor Response
- Hemiparesis, hemiplegia, and decreased muscle tone
- Cranial nerve dysfunction, especially cranial nerves III, IV, VI, VII, and VIII

Memory Changes
- Short attention span
- Personality and behavioral changes
- Bewilderment

BOX 59.5 Glasgow Coma Scale

Score
- The lowest possible score is 3 points (deep coma or death).
- The highest possible score is 15 points (fully awake).

Motor Response Points
- Obeys a simple response = 6
- Localizes painful stimuli = 5
- Normal flexion (withdrawal) = 4
- Abnormal flexion (decorticate posturing) = 3
- Extensor response (decerebrate posturing) = 2
- No motor response to pain = 1

Verbal Response Points
- Oriented = 5
- Confused conversation = 4
- Inappropriate words = 3
- Responds with incomprehensible sounds = 2
- No verbal response = 1

Eye-Opening Points
- Spontaneous = 4
- In response to sound = 3
- In response to pain = 2
- No response, even to painful stimuli = 1

Data from Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. p. 835.

2. Parasympathetic function, cholinergic responses
   a. Decreased pulse and blood pressure
   b. Constricted pupils
   c. Increased salivation
   d. Increased peristalsis
   e. Dilated blood vessels
   f. Bladder contraction

L. Assessment of sensory function: Touch, pressure, pain

M. Glasgow Coma Scale (Box 59.5)
1. The scale is a method of assessing a client's neurological condition.
2. The scoring system is based on a scale of 3 to 15 points.
3. A score lower than 8 indicates that coma is present.

IV. The Unconscious Client

A. Description
1. The unconscious client is in a state of depressed cerebral functioning with unresponsiveness to stimulation of sensory and motor function.
2. Some causes include head trauma, cerebral toxins, shock, hemorrhage, tumor, and infection.

B. Assessment
1. Unarousable
2. Primitive or no response to painful stimuli
3. Altered respirations
4. Decreased cranial nerve and reflex activity

C. Interventions (Box 59.6)

V. Increased Intracranial Pressure (ICP)

A. Description
1. Increased ICP may be caused by trauma, hemorrhage, growths or tumors, hydrocephalus, edema, or inflammation.
2. Increased ICP can impede circulation to the brain, impede the absorption of CSF, affect the functioning of nerve cells, and lead to brainstem compression and death.

B. Assessment (see Clinical Judgment: Analyze Cues Box)
1. Altered level of consciousness, which is the most sensitive and earliest indication of increasing ICP
2. Headache
3. Abnormal respirations (see Box 59.2)
4. Rise in blood pressure with widening pulse pressure
5. Slowing of pulse
6. Elevated temperature
7. Vomiting
8. Pupil changes
9. Late signs of increased ICP include increased systolic blood pressure, widened pulse pressure, and slowed heart rate.

Telegram & Insta: NCLEX_RN_Edu

BOX 59.6 Care of the Unconscious Client

- Assess patency of the airway and keep airway and emergency equipment readily available.
- Monitor blood pressure, pulse, and heart sounds.
- Assess respiratory and circulatory status.
- Do not leave the client unattended if unstable.
- Maintain a patent airway and ventilation, because a high carbon dioxide (CO_2) level increases intracranial pressure.
- Assess lung sounds for the accumulation of secretions; suction as needed.
- Assess neurological status, including level of consciousness, pupillary reactions, and motor and sensory function, using a coma scale.
- Place the client in a semi-Fowler's position.
- Change position of the client every 2 hours, avoiding injury when turning.
- Avoid Trendelenburg's position.
- Use side rails unless contraindicated or according to agency protocol.
- Assess for edema.
- Monitor for dehydration.
- Monitor intake and output and daily weight.
- Maintain NPO (nothing by mouth) status until consciousness returns.
- Maintain nutrition as prescribed (intravenous or enteral feedings), and monitor fluid and electrolyte balance (when consciousness returns, check the gag and swallow reflex before resuming a diet).
- Assess bowel sounds.
- Monitor elimination patterns.
- Monitor for constipation, impaction, and paralytic ileus.
- Maintain urinary output to prevent stasis, infection, and calculus formation.
- Monitor the status of skin integrity.
- Initiate measures to prevent skin breakdown.
- Provide frequent mouth care.
- Remove dentures and contact lenses.
- Assess the eyes for the presence of a corneal reflex and irritation, and instill artificial tears or cover the eyes with eye patches.
- Monitor drainage from the ears or nose for the presence of cerebrospinal fluid.
- Assume that the unconscious client can hear.
- Avoid restraints where possible.
- Initiate seizure precautions if necessary.
- Provide range-of-motion exercises to prevent contractures.
- Use a footboard or high-topped sneakers to prevent footdrop.
- Use splints to prevent wrist deformities.
- Initiate physical therapy as appropriate.

10. Other late signs include changes in motor function from weakness to **hemiplegia**, a positive **Babinski's reflex**, decorticate or decerebrate posturing, and seizures.

C. Interventions

1. Monitor respiratory status and prevent hypoxia.
2. Monitor ICP if a pressure device is in place. (Refer to Chapter 70.)
3. Avoid the administration of morphine sulfate to prevent the occurrence of hypoxia.
4. Maintain mechanical ventilation as prescribed; maintaining the $PaCO_2$ at 30 to 35 mm Hg will result in vasoconstriction of the cerebral blood vessels, decreased blood flow, and therefore decreased ICP.
5. Maintain body temperature.
6. Prevent shivering, which can increase ICP.
7. Decrease environmental stimuli.
8. Monitor electrolyte levels and acid–base balance.
9. Monitor intake and output.
10. Limit fluid intake to 1200 mL/day.
11. Instruct the client to avoid straining activities, such as coughing and sneezing.
12. Instruct the client to avoid Valsalva's maneuver.

For the client with increased ICP, elevate the head of the bed 30 to 40 degrees, avoid the Trendelenburg's position, and prevent flexion of the neck and hips.

D. Medications (Box 59.7)

CLINICAL JUDGMENT: ANALYZE CUES

Health History

The nurse is monitoring a client who sustained a head injury after being hit in the side of the head with a baseball bat. The client was admitted to the neurological unit at 1300.

Nurses' Notes

1300: Alert and oriented and complaining of a headache as 3/10 on a 1 to 10 pain intensity scale.
Moving all extremities, pupils are equal and reactive, PERRLA. Glasgow Coma Scale is 15.
1400: Restless. Pupils: slow to react. Glasgow Coma Scale is 11.

Vital Signs

1300: Temperature 98.8° F (37.1° C), pulse 82 beats per minute, respirations 20 breaths per minute and regular, blood pressure 130/88 mmHg.
1400: Temperature 100.8° F (38.2° C), pulse 60 beats per minute, respirations 18 breaths per minute and irregular, blood pressure 150/68 mmHg.

The nurse analyzes the cues and notes the changes in the client. The nurse determines that the client's condition has deteriorated and is indicative of increased intracranial pressure.

Telegram & Insta: NCLEX_RN_Edu

BOX 59.7 Medications for Increased Intracranial Pressure

Antiseizure
- Seizures increase metabolic requirements and cerebral blood flow and volume, thus increasing intracranial pressure (ICP).
- Medications may be given prophylactically to prevent seizures.

Antipyretics and Muscle Relaxants
- Temperature reduction decreases metabolism, cerebral blood flow, and thus ICP.
- Antipyretics prevent temperature elevations.
- Muscle relaxants prevent shivering.

Blood Pressure Medication
- Blood pressure medication may be required to maintain cerebral perfusion at a normal level.
- Notify the primary health care provider if the blood pressure range is lower than 100 or higher than 150 mm Hg systolic.

Corticosteroids
- Corticosteroids stabilize the cell membrane and reduce leakiness of the blood-brain barrier.
- Corticosteroids decrease cerebral edema.
- A histamine blocker may be administered to counteract the excess gastric secretion that occurs with the corticosteroid.
- Clients must be withdrawn slowly from corticosteroid therapy to reduce the risk of adrenal crisis.

Intravenous Fluids
- Fluids are administered intravenously via an infusion pump to control the amount administered.
- Infusions are monitored closely because of the risk of promoting additional cerebral edema and fluid overload.

Hyperosmotic Agent (Osmotic Diuretic)
- A hyperosmotic agent increases intravascular pressure by drawing fluid from the interstitial spaces and from the brain cells.
- Monitor renal function.
- Diuresis is expected.

E. Surgical intervention: Also see Chapter 39 for additional information on ventriculoperitoneal shunts (Box 59.8).

VI. Hyperthermia

A. Description
1. Temperature higher than 105° F (40.6° C), which increases the cerebral metabolism and increases the risk of hypoxia
2. Causes include infection, heat stroke, exposure to high environmental temperatures, and dysfunction of the thermoregulatory center.

B. Assessment
1. Temperature higher than 105° F (40.6° C)
2. Shivering
3. Nausea and vomiting

BOX 59.8 Surgical Intervention for Chronic Increased Intracranial Pressure: Ventriculoperitoneal Shunt

Description
- A ventriculoperitoneal shunt diverts cerebrospinal fluid from the ventricles into the peritoneum.

Postprocedure Interventions
- Position the client supine and turn from the back to the nonoperative side.
- Monitor for signs of increasing intracranial pressure resulting from shunt failure.
- Monitor for signs of infection.

C. Interventions
1. Maintain a patent airway.
2. Initiate seizure precautions.
3. Monitor intake and output and assess the skin and mucous membranes for signs of dehydration.
4. Monitor lung sounds.
5. Monitor for dysrhythmias.
6. Assess peripheral pulses for systemic blood flow.
7. Induce normothermia with fluids, cool baths, fans, or a hypothermia blanket.

D. Inducement of normothermia
1. Prevent shivering, which will increase ICP and oxygen consumption.
2. Administer medications as prescribed to prevent shivering and to lower body temperature.
3. Monitor neurological status.
4. Monitor for infection and respiratory complications because hyperthermia may mask the signs of infection.
5. Monitor for cardiac dysrhythmias.
6. Monitor intake and output and fluid balance.
7. Prevent trauma to the skin and tissues.
8. Apply lotion to the skin frequently.
9. Inspect for frostbite if a hypothermia blanket is used.

VII. Traumatic Head Injury

A. Description
1. Head injury is trauma to the skull, resulting in mild to extensive damage to the brain.
2. Immediate complications include cerebral bleeding, hematomas, uncontrolled increased ICP, infections, and seizures.
3. Changes in personality or behavior, cranial nerve deficits, and any other residual deficits depend on the area of the brain damage and the extent of the damage.

B. Types of head injuries (Box 59.9)
1. Open
   - **a.** Scalp lacerations
   - **b.** Fractures in the skull
   - **c.** Interruption of the dura mater

Telegram & Insta: NCLEX_RN_Edu

BOX 59.9 Types of Head Injuries

Concussion
- Concussion is a jarring of the brain within the skull; there may or may not be a loss of consciousness.

Contusion
- Contusion is a bruising type of injury to the brain tissue.
- Contusion may occur along with other neurological injuries, such as with subdural or extradural collections of blood.

Skull Fractures
- Linear
- Depressed
- Compound
- Comminuted

Epidural Hematoma
- The most serious type of hematoma, epidural hematoma forms rapidly and results from arterial bleeding.
- The hematoma forms between the dura and skull from a tear in the meningeal artery.
- It is often associated with temporary loss of consciousness, followed by a lucid period that then rapidly progresses to coma.
- Epidural hematoma is a surgical emergency.

Subdural Hematoma
- Subdural hematoma forms slowly and results from a venous bleed.
- It occurs under the dura as a result of tears in the veins crossing the subdural space.

Intracerebral Hemorrhage
- Intracerebral hemorrhage occurs when a blood vessel within the brain ruptures, allowing blood to leak inside the brain.

Subarachnoid Hemorrhage
- A subarachnoid hemorrhage is bleeding into the subarachnoid space. It may occur as a result of head trauma or spontaneously, such as from a ruptured cerebral aneurysm.

2. Closed
   - **a.** Concussions
   - **b.** Contusions
   - **c.** Fractures

C. Hematoma

1. Description: A collection of blood in the tissues that can occur as a result of a subarachnoid hemorrhage or an intracerebral hemorrhage.
2. Assessment
   - **a.** Assessment findings depend on the injury.
   - **b.** Clinical manifestations usually result from increased ICP.
   - **c.** Changing neurological signs in the client
   - **d.** Changes in level of consciousness
   - **e.** Airway and breathing pattern changes
   - **f.** Vital signs change, reflecting increased ICP.
   - **g.** Headache, nausea, and vomiting
   - **h.** Visual disturbances, pupillary changes, and papilledema
   - **i.** Nuchal rigidity (not tested until spinal cord injury is ruled out)
   - **j.** CSF drainage from the ears or nose
   - **k.** Weakness and paralysis
   - **l.** Posturing
   - **m.** Decreased sensation or absence of feeling
   - **n.** Reflex activity changes
   - **o.** Seizure activity

CSF can be distinguished from other fluids by the presence of concentric rings (bloody fluid surrounded by yellowish stain; halo sign) when the fluid is placed on a white sterile background, such as a gauze pad. CSF also tests positive for glucose when tested using a strip test.

3. Interventions
   - **a.** Monitor respiratory status and maintain a patent airway, because increased carbon dioxide (CO_2) levels increase cerebral edema.
   - **b.** Monitor neurological status and vital signs, including temperature.
   - **c.** Monitor for increased ICP.
   - **d.** Maintain head elevation to reduce venous pressure.
   - **e.** Prevent neck flexion.
   - **f.** Initiate normothermia measures for increased temperature.
   - **g.** Assess cranial nerve function, reflexes, and motor and sensory function.
   - **h.** Initiate seizure precautions.
   - **i.** Monitor for pain and restlessness.
   - **j.** Morphine sulfate or opioid medication may be prescribed to decrease agitation and control restlessness caused by pain for the head-injured client on a ventilator; administer with caution because it is a respiratory depressant and may increase ICP.
   - **k.** Monitor for drainage from the nose or ears, because this fluid may be CSF.
   - **l.** Do not attempt to clean the nose, suction, or allow the client to blow their nose if drainage occurs.
   - **m.** Do not clean the ear if drainage is noted, but apply a loose, dry sterile dressing.
   - **n.** Check drainage for the presence of CSF.
   - **o.** Notify the PHCP if drainage from the ears or nose is noted and if the drainage tests positive for CSF.
   - **p.** Instruct the client to avoid coughing because this increases ICP.
   - **q.** Monitor for signs of infection.
   - **r.** Prevent complications of immobility.
   - **s.** Inform the client and family about the possible behavior changes that may occur, including those that are expected and those that need to be reported.

Telegram & Insta: NCLEX_RN_Edu

D. Craniotomy
1. Description
   - **a.** Surgical procedure that involves an incision through the cranium to remove accumulated blood or a tumor
   - **b.** Complications of the procedure include increased ICP from cerebral edema, hemorrhage, or obstruction of the normal flow of CSF.
   - **c.** Additional complications include hematomas, hypovolemic shock, hydrocephalus, respiratory and neurogenic complications, pulmonary edema, and wound infections.
   - **d.** Complications related to fluid and electrolyte imbalances include **diabetes insipidus** and inappropriate secretion of antidiuretic hormone.
   - **e.** Stereotactic radiosurgery (SRS) may be an alternative to traditional surgery and is usually used to treat tumors and arteriovenous malformations.
2. Preoperative interventions
   - **a.** Explain the procedure to the client and family.
   - **b.** Prepare to shave the client's head as prescribed (usually done in the operating room) and cover the head with an appropriate covering.
   - **c.** Stabilize the client before surgery.
3. Postoperative interventions (Box 59.10)
4. Postoperative positioning (Box 59.11)

VIII. Spinal Cord Injuries (Refer to Chapter 70)

IX. Cerebral Aneurysm

A. Description: Dilation of the walls of a weakened cerebral artery; can lead to rupture

B. Assessment
1. Headache and pain
2. Irritability
3. Visual changes
4. Tinnitus
5. **Hemiparesis**
6. Nuchal rigidity
7. Seizures

C. Interventions
1. Maintain a patent airway (suction only with a PHCP's prescription).
2. Administer oxygen as prescribed.
3. Monitor vital signs and for hypertension or dysrhythmias.
4. Avoid taking temperatures via the rectum.
5. Initiate aneurysm precautions (Box 59.12).

X. Seizures

A. Description
1. Seizures are an abnormal, sudden, excessive discharge of electrical activity within the brain.
2. Epilepsy is a disorder characterized by chronic seizure activity and indicates brain or CNS irritation.
3. Causes include genetic factors, trauma, tumors, circulatory or metabolic disorders, toxicity, and infections.
4. Status epilepticus involves a rapid succession of epileptic spasms without intervals of consciousness; it is a potential complication that can occur with any type of seizure, and brain damage may result.

B. Types of seizures (Box 59.13)

C. Assessment
1. Seizure history
2. Type of seizure

BOX 59.10 Nursing Care Following Craniotomy

- Monitor vital signs and neurological status every 30 to 60 minutes.
- Maintain head of bed at least 30 degrees unless otherwise contraindicated.
- Monitor for increased intracranial pressure (ICP) (see Chapter 70).
- Monitor for decreased level of consciousness, motor weakness or paralysis, aphasia, visual changes, and personality changes.
- Maintain mechanical ventilation and slight hyperventilation for the first 24 to 48 hours as prescribed to prevent increased ICP.
- Assess the PHCP's prescription regarding client positioning.
- Avoid extreme hip or neck flexion, and maintain the head in a midline neutral position.
- Provide a quiet environment.
- Monitor the head dressing frequently for signs of drainage.
- Mark any area of drainage at least once each nursing shift for baseline comparison.
- Monitor the drain, which may be in place for 24 hours; maintain suction on the drain as prescribed.
- Measure drainage from the drain every 8 hours, and record the amount and color.
- Notify the PHCP if drainage is more than the normal amount of 30 to 50 mL per shift.
- Notify the PHCP immediately of excessive amounts of drainage or a saturated head dressing.
- Record strict measurement of hourly intake and output.
- Maintain fluid restriction at 1500 mL/day as prescribed.
- Monitor electrolyte levels.
- Monitor for dysrhythmias, which may occur as a result of fluid or electrolyte imbalance.
- Apply ice packs or cool compresses as prescribed; expect periorbital edema and ecchymosis of one or both eyes.
- Provide range-of-motion exercises every 8 hours.
- Place antiembolism stockings on the client as prescribed.
- Administer antiseizure medications, antacids, corticosteroids, and antibiotics as prescribed.
- Administer analgesics such as codeine sulfate or acetaminophen as prescribed for pain.

Telegram & Insta: NCLEX_RN_Edu

BOX 59.11 Client Positioning Following Craniotomy

- Positions prescribed following a craniotomy vary with the type of surgery and the specific postoperative PHCP's prescription.
- Always check the PHCP's prescription regarding client positioning.
- Incorrect positioning may cause serious and possibly fatal complications.

Removal of a Bone Flap for Decompression

- To facilitate brain expansion, the client should be turned from the back to the nonoperative side, but not to the side on which the operation was performed.

Posterior Fossa Surgery

- To protect the operative site from pressure and minimize tension on the suture line, position the client on the side, with a pillow under the head for support, and not on the back.

Infratentorial Surgery

- Infratentorial surgery involves surgery below the tentorium of the brain.
- The PHCP may prescribe a flat position without head elevation or may prescribe that the head of the bed be elevated at 30 to 45 degrees.
- Do not elevate the head of the bed in the acute phase of care following surgery without a PHCP's prescription.

Supratentorial Surgery

- Supratentorial surgery involves surgery above the tentorium of the brain.
- The PHCP may prescribe that the head of the bed be elevated at 30 degrees to promote venous outflow through the jugular veins.
- Do not lower the head of the bed in the acute phase of care following surgery without a PHCP's prescription.

BOX 59.12 Aneurysm Precautions

- Maintain the client on bed rest in a semi-Fowler's or a side-lying position.
- Maintain a darkened room (subdued lighting and avoid direct, bright, artificial lights) without stimulation (a private room is optimal).
- Provide a quiet environment (avoid activities or startling noises); a telephone in the room is not usually allowed.
- Reading, watching television, and listening to music are permitted, provided that they do not overstimulate the client.
- Limit visitors.
- Maintain fluid restrictions.
- Provide diet as prescribed; avoid stimulants in the diet.
- Prevent any activities that initiate the Valsalva maneuver (straining at stool, coughing); provide stool softeners to prevent straining.
- Administer care gently (such as the bath, back rub, range of motion).
- Limit invasive procedures.
- Maintain normothermia.
- Prevent hypertension.
- Provide sedation.
- Provide pain control.
- Administer prophylactic antiseizure medications.
- Provide deep vein thrombosis (DVT) prophylaxis as prescribed.

3. Occurrences before, during, and after the seizure
4. Prodromal signs, such as mood changes, irritability, and insomnia
5. Aura: Sensation that warns the client of the impending seizure
6. Loss of motor activity or bowel and bladder function or loss of consciousness during the seizure
7. Occurrences during the postictal state, such as headache, loss of consciousness, sleepiness, and impaired speech or thinking

D. Interventions

⚠ If the client is having a seizure, maintain a patent airway. Do not force the jaws open or place anything in the client's mouth.

1. Note the time and duration of the seizure.
2. Assess behavior at the onset of the seizure: If the client has experienced an aura, if a change in facial expression occurred, or if a sound or cry occurred from the client.
3. If the client is standing or sitting, place the client on the floor and protect the head and body.
4. Support airway, breathing, and circulation.
5. Administer oxygen.
6. Prepare to suction secretions.
7. Turn the client to the side to allow secretions to drain while maintaining the airway.
8. Prevent injury during the seizure.
9. Remain with the client.
10. Do not restrain the client.
11. Loosen restrictive clothing.
12. Note the type, character, and progression of the movements during the seizure.
13. Monitor for incontinence.
14. Administer intravenous medications as prescribed to stop the seizure.
15. Document the characteristics of the seizure.
16. Provide privacy.
17. Monitor behavior following the seizure, such as the state of consciousness, motor ability, and speech ability.
18. Instruct the client about the importance of lifelong medication and the need for follow-up determination of medication blood levels.
19. Instruct the client to avoid alcohol, excessive stress, fatigue, and strobe lights.

Telegram & Insta: NCLEX_RN_Edu

BOX 59.13 Types of Seizures

Generalized Seizures

Tonic-Clonic

- Tonic-clonic seizures may begin with an aura.
- The tonic phase involves the stiffening or rigidity of the muscles of the arms and legs and usually lasts 10 to 20 seconds, followed by loss of consciousness.
- The clonic phase consists of hyperventilation and jerking of the extremities and usually lasts about 30 seconds.
- Full recovery from the seizure may take several hours.

Absence

- A brief seizure that lasts seconds, and the individual may or may not lose consciousness.
- No loss or change in muscle tone occurs.
- Seizures may occur several times during a day.
- The victim appears to be daydreaming.
- This type of seizure is more common in children.

Myoclonic

- Myoclonic seizures present as a brief generalized jerking or stiffening of extremities.
- The victim may fall from the seizure.

Atonic or Akinetic (Drop Attacks)

- An atonic seizure is a sudden momentary loss of muscle tone.
- The victim may fall as a result of the seizure.

Partial Seizures

Simple Partial

- The simple partial seizure produces sensory symptoms accompanied by motor symptoms that are localized or confined to a specific area.
- The client remains conscious and may report an aura.

Complex Partial

- The complex partial seizure is a psychomotor seizure.
- The area of the brain most usually involved is the temporal lobe.
- The seizure is characterized by periods of altered behavior of which the client is not aware.
- The client loses consciousness for a few seconds.

BOX 59.14 Clinical Manifestations of Stroke Based on Type

Thrombotic Stroke

- Typically, there is no decreased level of consciousness within the first 24 hours.
- Symptoms get progressively worse as the infarction and edema increase.

Embolic Stroke

- Sudden, severe symptoms
- Warning signs are less common.
- Client remains conscious and may have a headache.

Hemorrhagic Stroke

- Sudden onset of symptoms
- Symptoms progress over minutes to hours due to ongoing bleeding.

20. Encourage the client to contact available community resources, such as the Epilepsy Foundation of America.
21. Encourage the client to wear a MedicAlert bracelet.

XI. Stroke

A. Description

1. A stroke, sometimes referred to as a brain attack, manifests as a sudden focal neurological deficit and is caused by cerebrovascular disease. Part of the brain cannot get the blood (and oxygen) it needs, causing brain cells to die.
2. Cerebral anoxia lasting longer than 10 minutes causes cerebral infarction with irreversible change.
3. Cerebral edema causes further dysfunction.
4. Diagnosis is determined by a CT scan, electroencephalography, cerebral arteriography, and MRI. In most facilities, the type of stroke needs to be determined within a certain time frame after arrival in order for timely treatment to be initiated.
5. Transient ischemic attack may be a warning sign of an impending stroke.
6. The permanent disability cannot be determined until the cerebral edema subsides.
7. The order in which function may return is facial, swallowing, lower limbs, speech, and arms.
8. Carotid endarterectomy is a surgical intervention used in stroke management; it is targeted at stroke prevention, especially in clients with symptomatic carotid stenosis.
9. The National Institutes of Health through the National Institute of Neurological Disorders and Stroke (NINDS) developed the *Know Stroke: Know the Signs. Act in Time* campaign, devised to help educate the public about the symptoms of stroke and the importance of getting to the hospital quickly (http://stroke.nih.gov).

B. Causes (Box 59.14)

1. Thrombosis
2. Embolism
3. Thrombotic and embolic strokes are classified as ischemic strokes.
4. Hemorrhage from rupture of a vessel; classified as a hemorrhagic stroke
5. Manifestations of different types of stroke are similar; therefore, it is critical to determine the type of stroke occurring. The type cannot be determined solely based on manifestations, and the correct and appropriate treatment for the stroke type must be initiated.

Telegram & Insta: NCLEX_RN_Edu

Right-brain damage (stroke on right side of the brain)	Left-brain damage (stroke on left side of the brain)
• Impaired judgment • Impaired time concepts • Impulsive, safety problems • Left-sided neglect • Paralyzed left side: hemiplegia • Rapid performance, short attention span • Spatial-perceptual deficits • Tends to deny or minimize problems	• Aware of deficits: depression, anxiety • Impaired comprehension related to language, math • Impaired right/left discrimination • Impaired speech/language aphasias • Paralyzed right side: hemiplegia • Slow performance, cautious

FIG. 59.2 Manifestations of right brain and left brain stroke.

C. Risk factors
1. Atherosclerosis
2. Hypertension
3. Anticoagulation therapy
4. **Diabetes mellitus**
5. Stress
6. Obesity
7. Oral contraceptives

D. Assessment (Fig. 59.2; Boxes 59.14 and 59.15)

A critical factor in the early intervention and treatment of stroke is the accurate identification of stroke manifestations and establishing the onset of the manifestations. Stroke screening scales may be used to identify stroke manifestations quickly. Identification of the type of stroke occurring is critical in determining the appropriate treatment. This is usually done using imaging such as a CT scan.

1. Assessment findings depend on the area of the brain affected; stroke scales such as the NIH Stroke Scale (stroke.nih.gov/resources/scale.htm) may be used by the health care facility for assessment.
2. In the screening process for stroke, many institutions check a finger-stick blood sugar to rule out hypoglycemia as the cause of altered mental status.
3. Lesions in the cerebral hemisphere result in manifestations on the contralateral side, which is the side of the body opposite the stroke.

BOX 59.15 Assessment Findings in a Stroke

Agnosia
- The inability to recognize familiar objects or persons

Apraxia
- Called *dyspraxia* if the condition is mild
- Characterized by loss of ability to execute or carry out skilled movements or gestures, despite having the desire and physical ability to perform them

Hemianopsia
- Blindness in half the visual field

Homonymous Hemianopsia
- Loss of half of the field of view on the same side in both eyes

Neglect Syndrome (Unilateral Neglect)
- Client unaware of the existence of the paralyzed side

Proprioception Alterations
- Altered position sense that places the client at increased risk of injury

Pyramid Point: With visual problems, the client must turn the head to scan the complete range of vision.

Data from U.S. Department of Health and Human Services, National Institutes of Health: *Know stroke: Know the signs. Act in time*, NIH Publication #10-4872. Bethesda, Md., June 2013, National Institutes of Health, http://stroke.nih.gov

4. Airway patency is always a priority.
5. Pulse (may be slow and bounding)
6. Respirations (Cheyne-Stokes)
7. Blood pressure (hypertension)
8. Headache, nausea, and vomiting
9. Facial drooping
10. Nuchal rigidity
11. Visual changes
12. Ataxia
13. Dysarthria
14. Dysphagia
15. Speech changes
16. Decreased sensation to pressure, heat, and cold
17. Bowel and bladder dysfunctions
18. Paralysis

E. Aphasia
1. Expressive
   - **a.** Damage occurs in Broca's area of the frontal brain.
   - **b.** The client understands what is said but is unable to communicate verbally.
2. Receptive
   - **a.** Injury involves Wernicke's area in the temporoparietal area.
   - **b.** The client is unable to understand the spoken and often the written word.
3. Global or mixed: Language dysfunction occurs in expression and reception.
4. Interventions for aphasia
   - **a.** Provide repetitive directions.
   - **b.** Break tasks down to one step at a time.

Telegram & Insta: NCLEX_RN_Edu

c. Repeat names of objects frequently used.
d. Allow time for the client to communicate.
e. Use a picture board, communication board, or computer technology.

F. Interventions during the acute phase of stroke
1. Maintain a patent airway and administer oxygen as prescribed.
2. Monitor vital signs.
3. Usually a blood pressure of 150/100 mm Hg is maintained to ensure cerebral perfusion.
4. Suction secretions to prevent aspiration as prescribed, but never suction nasally or for longer than 10 seconds to prevent increased ICP.
5. Monitor for increased ICP, because the client is most at risk during the first 72 hours following the stroke.
6. Position the client on the side to prevent aspiration, with the head of the bed elevated 15 to 30 degrees as prescribed.
7. Monitor level of consciousness, pupillary response, motor and sensory response, cranial nerve function, and reflexes.
8. Maintain a quiet environment.
9. Insert a urinary catheter as prescribed.
10. Administer intravenous fluids as prescribed.
11. Maintain fluid and electrolyte balance.
12. Prepare to administer anticoagulants, antiplatelets, diuretics, antihypertensives, and antiseizure medications as prescribed depending on the type of stroke that has been diagnosed.
13. Establish a form of communication.

G. Interventions in the postacute phase of a stroke
1. Continue with interventions from the acute phase.
2. Position the client 2 hours on the unaffected side and 20 minutes on the affected side; the prone position may also be prescribed.
3. Provide skin, mouth, and eye care.
4. Perform passive range-of-motion exercises to prevent contractures.
5. Place antiembolism stockings on the client; remove daily to check skin.
6. Monitor the gag reflex and ability to swallow.
7. Provide sips of fluids and slowly advance diet to foods that are easy to chew and swallow.
8. Provide soft and semisoft foods and flavored, cool or warm, thickened fluids rather than thin liquids, because the stroke client can tolerate these types of food better; speech therapists may do swallow studies to recommend consistency of food and fluids.
9. When the client is eating, position the client sitting in a chair or sitting up in bed, with the head and neck positioned slightly forward and flexed.
10. Place food in the back of the mouth on the unaffected side to prevent trapping of food in the affected cheek.

H. Interventions in the chronic phase of stroke (see Clinical Judgment: Take Action Box)
1. Neglect syndrome
a. The client is unaware of the existence of the paralyzed side (unilateral neglect), which places the client at risk for injury.
b. Teach the client to touch and use both sides of the body.
2. Hemianopsia
a. The client has blindness in half of the visual field.
b. Homonymous hemianopsia is blindness in the same visual field of both eyes.
c. Encourage the client to turn the head to scan the complete range of vision; otherwise, the client does not see half of the visual field.
3. Approach the client from the unaffected side.
4. Place the client's personal objects within the visual field.
5. Provide eye care for visual deficits.
6. Place a patch over the affected eye if the client has diplopia.
7. Increase mobility as tolerated.
8. Encourage fluid intake and a high-fiber diet.
9. Administer stool softeners as prescribed.
10. Encourage the client to express feelings.
11. Encourage independence in activities of daily living.
12. Assess the need for assistive devices such as a cane, walker, splint, or braces.
13. Teach transfer technique from bed to chair and from chair to bed.
14. Provide gait training.
15. Initiate physical and occupational therapy for assessment and to determine the need for adaptive equipment or other supports for self-care and mobility.
16. Refer client to a speech and language pathologist as prescribed.
17. Encourage the client and family to contact available community resources.

CLINICAL JUDGMENT: TAKE ACTION

The nurse notes that a hospitalized client who experienced a stroke is sitting in a chair and is leaning to the left with one arm caught in the side of the chair seat. The nurse suspects that the client is experiencing unilateral neglect syndrome and takes the following actions:

- Checks the client for signs of injury and repositions the client
- Provides for a safe environment for the client
- Teaches the client to use both sides of the body and to attend to the affected side first
- Asks the client if there is difficulty with sight and if so, teaches the client to turn the head from side to side to expand the visual field

Telegram & Insta: NCLEX_RN_Edu

XII. Multiple Sclerosis

A. Description

1. A degenerative disorder of the CNS that is characterized by demyelinization of the neurons. It is a chronic, progressive, and noncontagious disorder.
2. It usually occurs between the ages of 20 and 50 years and consists of periods of remissions and exacerbations.
3. The causes are unknown, but the disease is thought to be the result of an autoimmune response or viral infection.
4. Precipitating factors include pregnancy, fatigue, stress, infection, and trauma.
5. Electroencephalographic findings are abnormal.
6. Assessment of a lumbar puncture indicates an increased gamma globulin level, but the serum globulin level is normal.

B. Assessment

1. Fatigue and weakness
2. Ataxia and vertigo
3. Tremors and spasticity of the lower extremities
4. Paresthesias
5. Blurred vision, diplopia, and transient blindness
6. Nystagmus
7. Dysphasia
8. Decreased perception to pain, touch, and temperature
9. Bladder and bowel disturbances, including urgency, frequency, retention, and incontinence
10. Abnormal reflexes, including hyperreflexia, absent reflexes, and a positive Babinski's reflex
11. Emotional changes such as apathy, euphoria, irritability, and depression
12. Memory changes and confusion

C. Interventions

1. The client with multiple sclerosis should be aware of triggers that cause worsening of the disease and avoid them where possible.
2. Provide energy conservation measures during exacerbation.
3. Protect the client from injury by providing safety measures.
4. Place an eye patch on the eye for diplopia.
5. Monitor for potential complications such as urinary tract infections, calculi, pressure ulcers, respiratory tract infections, and contractures.
6. Promote regular elimination by bladder and bowel training.
7. Encourage independence.
8. Assist the client to establish a regular exercise and rest program and to balance moderate activity with rest periods.
9. Assess the need for assistive devices, and provide as needed.
10. Initiate physical and speech therapy.
11. Instruct the client to avoid fatigue, stress, infection, overheating, and chilling.
12. Instruct the client to increase fluid intake and eat a balanced diet, including low-fat, high-fiber foods and foods high in potassium.
13. Instruct the client in safety measures related to sensory loss, such as regulating the temperature of bath water and avoiding heating pads.
14. Instruct the client in safety measures related to motor loss, such as avoiding the use of scatter rugs and using assistive devices.
15. Instruct the client in the self-administration of prescribed medications.
16. Anticholinergic agents are used for bladder spasticity and intravenous glucocorticoids for acute flare-ups.
17. Provide information about the National Multiple Sclerosis Society. (https://www.nationalmssociety.org)

XIII. Myasthenia Gravis

A. Description

1. A neuromuscular autoimmune disorder of the neuromuscular junction characterized by considerable weakness and abnormal fatigue of the voluntary muscles
2. A defect in the transmission of nerve impulses at the myoneural junction occurs.
3. Causes include insufficient secretion of acetylcholine, excessive secretion of cholinesterase, and unresponsiveness of the muscle fibers to acetylcholine.

B. Assessment

1. Weakness and fatigue
2. Difficulty chewing and swallowing
3. Dysphagia
4. Ptosis
5. Diplopia
6. Weak, hoarse voice
7. Difficulty breathing
8. Diminished breath sounds
9. Respiratory paralysis and failure

C. Interventions

1. Monitor respiratory status and ability to cough and deep-breathe adequately.
2. Monitor for respiratory failure.
3. Maintain suctioning and emergency equipment at the bedside.
4. Monitor vital signs.
5. Monitor speech and swallowing abilities to prevent aspiration.
6. Encourage the client to sit up when eating.
7. Assess muscle status.
8. Instruct the client to conserve strength.
9. Plan short activities that coincide with times of maximal muscle strength.
10. Monitor for myasthenic and cholinergic crises.

Telegram & Insta: NCLEX_RN_Edu

11. Administer anticholinesterase medications as prescribed.
12. Instruct the client to avoid stress, infection, fatigue, and over-the-counter medications.
13. Many medications are known to exacerbate MS, such as fluoroquinolones, beta blockers, and magnesium; the nurse needs to conduct a careful medication reconciliation.
14. Instruct the client to wear a MedicAlert bracelet.
15. Inform the client about services from the Myasthenia Gravis Foundation.

D. Anticholinesterase medications: Increase levels of acetylcholine at the myoneural junction (see Chapter 60)

E. Myasthenic crisis

1. Description
   - **a.** An acute exacerbation of the disease
   - **b.** The crisis is caused by a rapid, unrecognized progression of the disease, inadequate amount of medication, infection, fatigue, or stress.
2. Assessment
   - **a.** Increased pulse, respirations, and blood pressure
   - **b.** Dyspnea, anoxia, and cyanosis
   - **c.** Bowel and bladder incontinence
   - **d.** Decreased urine output
   - **e.** Absent cough and swallow reflex
3. Interventions
   - **a.** Assess for signs of myasthenic crisis.
   - **b.** Increase anticholinesterase medication, as prescribed.

F. Cholinergic crisis

1. Description
   - **a.** Results in depolarization of the motor end plates
   - **b.** The crisis is caused by overmedication with anticholinesterase.
2. Assessment
   - **a.** Abdominal cramps
   - **b.** Nausea, vomiting, and diarrhea
   - **c.** Blurred vision
   - **d.** Pallor
   - **e.** Pupillary miosis
   - **f.** Facial muscle twitching
   - **g.** Hypotension
   - **h.** Increased bronchial secretions, tearing, perspiration
   - **i.** Bronchospasm, wheezing, and bradycardia
3. Interventions
   - **a.** Withhold anticholinesterase medication.
   - **b.** Prepare to administer the antidote, atropine sulfate, if prescribed.
   - **c.** Monitor vital signs and respiratory status closely; intubation may be necessary.
   - **d.** Frequent monitoring of respiratory status is needed, and elective intubation may be initiated.

G. Edrophonium (Tensilon) test

⚠ Have atropine sulfate available when performing the edrophonium test.

1. Description
   - **a.** This test is performed by the neurologist and may be done to diagnose myasthenia gravis and to differentiate between myasthenic crisis and cholinergic crisis.
   - **b.** The test places the client at risk for ventricular fibrillation and cardiac arrest; emergency equipment needs to be available.
2. Myasthenia gravis is diagnosed through history and physical examination done by the PHCP. An edrophonium test or electromyography (EMG) may be utilized in the diagnosis process (see Chapter 61 for information on the EMG procedure).
3. Edrophonium test procedure
   - **a.** Edrophonium injection is administered to the client.
   - **b.** Positive for myasthenia gravis: Client shows improvement in muscle strength after the administration of edrophonium.
   - **c.** Negative for myasthenia gravis: Client shows no improvement in muscle strength, and strength may even deteriorate after injection of edrophonium.
4. To differentiate crisis
   - **a.** Myasthenic crisis: Edrophonium is administered; if strength improves, the client needs more medication.
   - **b.** Cholinergic crisis: Edrophonium is administered; if weakness is more severe, the client is overmedicated; prepare to administer atropine sulfate, the antidote, as prescribed.

XIV. Parkinson's Disease

A. Description

1. A degenerative disease caused by the depletion of dopamine, which interferes with the inhibition of excitatory impulses, resulting in a dysfunction of the extrapyramidal system.
2. It is a slow, progressive disease that results in a crippling disability.
3. The debilitation can result in falls, self-care deficits, failure of body systems, and depression.
4. Mental deterioration occurs late in the disease.

B. Assessment

1. Bradykinesia, abnormal slowness of movement, and sluggishness of physical and mental responses
2. Akinesia
3. Monotonous speech
4. Handwriting that becomes progressively smaller

Telegram & Insta: NCLEX_RN_Edu

5. Tremors in hands and fingers at rest (pill rolling)
6. Tremors increasing when fatigued and decreasing with purposeful activity or sleep
7. Rigidity with jerky movements
8. Restlessness and pacing
9. Blank facial expression; masklike face
10. Drooling
11. Difficulty swallowing and speaking
12. Loss of coordination and balance
13. Shuffling steps, stooped position, and propulsive gait

C. Interventions

1. Assess neurological status.
2. Assess ability to swallow and chew.
3. Provide high-calorie, high-protein, high-fiber soft diet with small, frequent feedings.
4. Increase fluid intake to 2000 mL/day.
5. Monitor for constipation.
6. Promote independence along with safety measures.
7. Avoid rushing the client with activities.
8. Assist with ambulation, and provide assistive devices.
9. Instruct the client to rock back and forth to initiate movement.
10. Instruct the client to wear low-heeled shoes.
11. Encourage the client to lift the feet when walking and to avoid prolonged sitting.
12. Provide a firm mattress and position the client prone, without a pillow, to facilitate proper posture.
13. Instruct in proper posture by teaching the client to hold the hands behind the back to keep the spine and neck erect.
14. Promote physical therapy and rehabilitation.
15. Medication therapy for Parkinson's disease is usually determined by shared decision-making, as side effects of drug therapy can affect quality of life.
16. Administer antiparkinsonian medications to increase the level of dopamine in the CNS.
17. Instruct the client to consult with the PHCP regarding foods high in vitamin B_6, because they block the effects of antiparkinsonian medications.
18. Avoid the use of monoamine oxidase inhibitors, because they will precipitate hypertensive crisis.
19. See Chapter 60 regarding medication to treat Parkinson's disease.

XV. Trigeminal Neuralgia

A. Description

1. A sensory disorder of the trigeminal (fifth cranial) nerve
2. It results in severe, recurrent, sharp facial pain along the trigeminal nerve.

B. Assessment

1. The client has severe pain on the lips, gums, or nose, or across the cheeks.
2. Situations that stimulate symptoms include cold, washing the face, chewing, or food or fluids of extreme temperatures.

C. Interventions

1. Instruct the client to avoid hot or cold foods and fluids.
2. Provide small feedings of liquid and soft foods.
3. Instruct the client to chew food on the unaffected side.
4. Administer medications as prescribed (see Chapter 60).

D. Surgical interventions

1. Microvascular decompression: Surgical relocation of the artery that compresses the trigeminal nerve as it enters the pons, which may relieve pain without compromising facial sensation
2. Radiofrequency waveforms: Create lesions that provide relief of pain without compromising touch or motor function
3. Rhizotomy: Resection of the root of the nerve to relieve pain
4. Glycerol injection: Destroys the myelinated fibers of the trigeminal nerve (may take up to 3 weeks for pain relief to occur)

XVI. Bell's Palsy (Facial Paralysis)

A. Description

1. Caused by a lower motor neuron lesion of cranial nerve VII that may result from infection, trauma, hemorrhage, meningitis, or tumor.
2. It results in paralysis of one side of the face.
3. Recovery usually occurs in a few weeks, without residual effects.

B. Assessment

1. Flaccid facial muscles
2. Frequently results in inability to raise the eyebrows, frown, smile, close the eyelids, or puff out the cheeks
3. Upward movement of the eye when attempting to close the eyelid
4. Loss of taste

C. Interventions

1. Encourage facial exercises to prevent the loss of muscle tone (a face sling may be prescribed to prevent stretching of weak muscles).
2. Protect the eyes from dryness, and prevent injury.
3. Promote frequent oral care.
4. Instruct the client to chew on the unaffected side.

Telegram & Insta: NCLEX_RN_Edu

XVII. Guillain-Barré Syndrome

A. Description
1. An acute infectious autoimmune neuronitis of the cranial and peripheral nerves. Generally occurs a few days to weeks after viral or bacterial infection.
2. The immune system overreacts to the infection and destroys the myelin sheath.
3. The syndrome usually is preceded by a mild upper respiratory infection or gastroenteritis.
4. The recovery is a slow process and can take years.

⚠ The major concern in Guillain-Barré syndrome is difficulty breathing; monitor respiratory status closely.

B. Assessment
1. Paresthesias
2. Pain and/or hypersensitivity such as with the weight of bedsheets or other items touching the body
3. Weakness of lower extremities
4. Gradual progressive weakness of the upper extremities and facial muscles
5. Possible progression to respiratory failure
6. Cardiac dysrhythmias
7. CSF that reveals an elevated protein level
8. Abnormal electroencephalogram

C. Interventions
1. Care is directed toward the treatment of symptoms, including pain management.
2. Monitor respiratory status closely.
3. Provide respiratory treatments.
4. Prepare to initiate respiratory support. During the acute phase of illness, ventilatory support is often a critical component of treatment.
5. Monitor cardiac status.
6. Assess for complications of immobility.
7. Provide the client and family with support.

XVIII. Amyotrophic Lateral Sclerosis (ALS)

A. Description
1. Also known as Lou Gehrig's disease
2. It is a progressive, rare, incurable degenerative disease involving the motor system.
3. The sensory and autonomic systems are not involved, and mental status changes do not result from the disease.
4. The cause of the disease may be related to an excess of glutamate, a chemical responsible for relaying messages between the motor neurons.
5. As the disease progresses, muscle weakness and atrophy develop until a flaccid tetraplegia develops.
6. Eventually, the respiratory muscles become affected, leading to respiratory compromise, pneumonia, and death.
7. No cure is known, and the treatment is symptomatic.

B. Assessment
1. Respiratory difficulty
2. Fatigue while talking
3. Muscle weakness and atrophy
4. Tongue atrophy
5. Dysphagia
6. Weakness of the hands and arms
7. Fasciculations of the face
8. Nasal quality of speech
9. Dysarthria

C. Interventions
1. Care is directed toward the treatment of symptoms.
2. Monitor respiratory status and institute measures to prevent aspiration.
3. Provide respiratory treatments.
4. Prepare to initiate respiratory support.
5. Assess for complications of immobility.
6. Address advance directives as appropriate.
7. Provide the client and family with psychosocial support.

XIX. Encephalitis

A. Description
1. An inflammation of the brain parenchyma and often of the meninges
2. It affects the cerebrum, brainstem, and cerebellum.
3. It most often is caused by a viral agent, although bacteria, fungi, or parasites also may be involved.
4. Viral encephalitis is almost always preceded by a viral infection.

B. Transmission
1. Arboviruses can be transmitted to human beings through the bite of an infected mosquito or tick.
2. Echovirus, coxsackievirus, poliovirus, herpes zoster virus, and viruses that cause mumps and chicken pox are common enteroviruses associated with encephalitis.
3. Herpes simplex type 1 virus can cause viral encephalitis.
4. The organism that causes amebic meningoencephalitis can enter the nasal mucosa of persons swimming in warm fresh water, such as a pond or lake.

C. Assessment
1. Changes in level of consciousness and mental status
2. Presence of cold sores, lesions, or ulcerations of the oral cavity
3. History of insect bites and swimming in fresh water
4. Exposure to infectious diseases
5. Travel to areas where the disease is prevalent
6. Fever
7. Nausea and vomiting
8. Nuchal rigidity

Telegram & Insta: NCLEX_RN_Edu

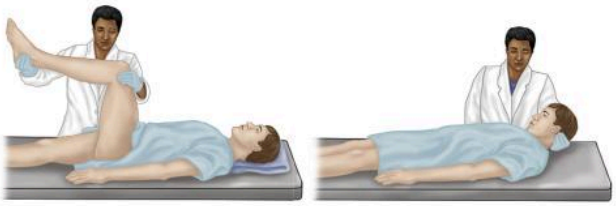


FIG. 59.3 Kernig's sign and Brudzinski's sign.

9. Signs of increased ICP
10. Motor dysfunction and focal neurological deficits

D. Interventions
1. Monitor vital and neurological signs.
2. Assess level of consciousness using the Glasgow Coma Scale.
3. Assess for mental status changes and personality and behavioral changes.
4. Assess for signs of increased ICP.
5. Assess for the presence of nuchal rigidity and a positive **Kernig's sign** or **Brudzinski's sign**, indicating meningeal irritation (Fig. 59.3).
6. Assist the client to turn, cough, and deep-breathe frequently.
7. Elevate the head of the bed 30 to 45 degrees.
8. Assess for muscle and neurological deficits.
9. Administer acyclovir as prescribed (usually the medication of choice for herpes encephalitis).
10. Initiate rehabilitation as needed for motor dysfunction or neurological deficits.

XX. West Nile Virus Infection

A. Description
1. A potentially serious illness that affects the CNS
2. The virus is contracted primarily by the bite of an infected mosquito (mosquitoes become carriers when they feed on infected birds).
3. Symptoms typically develop between 3 and 14 days after being bitten by the infected mosquito.
4. Neurological effects can be permanent.

B. Assessment
1. Many individuals will experience no symptoms.
2. Mild symptoms include fever; headache and body aches; nausea; vomiting; swollen glands; or a rash on the chest, stomach, or back.
3. Severe symptoms include a high fever, headache, neck stiffness, stupor, disorientation, tremors, muscle weakness, vision loss, numbness, paralysis, seizures, or coma.

C. Interventions are supportive; there is no specific treatment for the virus.

D. Prevention
1. Use insect repellents containing DEET (diethyltoluamide) when outdoors, and wear long sleeves and pants and light-colored clothing.
2. Stay indoors at dusk and dawn, when mosquitoes are most active.
3. Ensure that breeding sites for mosquitoes, such as standing water and water in bird baths, are eliminated. Keep wading pools empty and on their sides when not in use.

XXI. Meningitis

A. Description
1. An inflammation of the arachnoid and pia mater of the brain and spinal cord
2. It is caused by bacterial and viral organisms, although fungal and protozoan meningitis also occur.
3. Predisposing factors include skull fractures, brain or spinal surgery, sinus or upper respiratory infections, the use of nasal sprays, and a compromised immune system.
4. CSF is analyzed to determine the diagnosis and type of meningitis. In meningitis, CSF is cloudy, with increased protein, increased white **blood cells,** and decreased glucose counts.

B. Transmission: Transmission occurs in areas of high population density and in crowded living areas such as college dormitories and prisons.

Transmission of meningitis is by direct contact, including droplet spread.

C. Assessment (see Box 59.4)
1. Sudden onset of fever, nuchal rigidity, and mild lethargy are the most common signs.
2. Deterioration in the level of consciousness
3. Photophobia
4. Signs of meningeal irritation, such as nuchal rigidity and a positive Kernig's sign and Brudzinski's sign
5. Red, macular rash with meningococcal meningitis
6. Abdominal and chest pain with viral meningitis

D. Interventions
1. Monitor vital signs and neurological signs.
2. Assess for signs of increased ICP.
3. Initiate seizure precautions.
4. Monitor for seizure activity.
5. Monitor for signs of meningeal irritation.
6. Perform cranial nerve assessment.
7. Assess peripheral vascular status (septic emboli may block circulation).
8. Maintain isolation precautions as necessary with bacterial meningitis.
9. Maintain urine and stool precautions with viral meningitis.
10. Maintain respiratory isolation for the client with pneumococcal meningitis.
11. Elevate the head of the bed 30 degrees, and avoid neck flexion and extreme hip flexion.
12. Prevent stimulation and restrict visitors.
13. Administer analgesics and/or antibiotics as prescribed.

Telegram & Insta: NCLEX_RN_Edu

PRACTICE QUESTIONS

1. The nurse is assessing the motor and sensory function of an unconscious client who sustained a head injury. The nurse would use which technique to test the client's peripheral response to pain?
   1. Sternal rub
   2. Pressure on nail beds
   3. Pressure on the orbital rim
   4. Squeezing of the sternocleidomastoid muscle

2. The nurse is caring for a client with increased intracranial pressure as a result of a head injury. The nurse would note which trend in vital signs if the intracranial pressure is rising?
   1. Increasing temperature, increasing pulse, increasing respirations, decreasing blood pressure
   2. Increasing temperature, decreasing pulse, decreasing respirations, increasing blood pressure
   3. Decreasing temperature, decreasing pulse, increasing respirations, decreasing blood pressure
   4. Decreasing temperature, increasing pulse, decreasing respirations, increasing blood pressure

3. A client recovering from a head injury is participating in care. The nurse determines that the client understands measures to prevent elevations in intracranial pressure if the nurse observes the client doing which activity?
   1. Blowing the nose
   2. Isometric exercises
   3. Coughing vigorously
   4. Exhaling during repositioning

4. A client has clear fluid leaking from the nose following a basilar skull fracture. Which finding would alert the nurse that cerebrospinal fluid is present?
   1. Fluid is clear and tests negative for glucose.
   2. Fluid is grossly bloody in appearance and has a pH of 6.
   3. Fluid clumps together on the dressing and has a pH of 7.
   4. Fluid separates into concentric rings and tests positive for glucose.

5. The nurse is caring for a client who begins to experience seizure activity while in bed. Which actions would the nurse take? **Select all that apply.**
   - ❑ 1. Loosening restrictive clothing.
   - ❑ 2. Restraining the client's limbs.
   - ❑ 3. Removing the pillow and raising padded side rails.
   - ❑ 4. Positioning the client to the side, if possible, with the head flexed forward.
   - ❑ 5. Keeping the curtain around the client and the room door open so that when help arrives, they can quickly enter to assist.

6. The nurse is assigned to care for a client with complete right-sided hemiparesis from a stroke (brain attack). Which characteristics are associated with this condition? **Select all that apply.**
   - ❑ 1. The client is aphasic.
   - ❑ 2. The client has weakness on the right side of the body.
   - ❑ 3. The client has complete bilateral paralysis of the arms and legs.
   - ❑ 4. The client has weakness on the right side of the face and tongue.
   - ❑ 5. The client has lost the ability to move the right arm but is able to walk independently.
   - ❑ 6. The client has lost the ability to ambulate independently but is able to feed and bathe self without assistance.

7. The nurse has instructed the family of a client with a stroke (brain attack) who has homonymous hemianopsia about measures to help the client overcome the deficit. Which statement suggests that the family understands the measures to use when caring for the client?
   1. "We need to discourage wearing eyeglasses."
   2. "We need to place objects in the impaired field of vision."
   3. "We need to approach from the impaired field of vision."
   4. "We need to encourage head turning to scan the lost visual field."

8. The nurse is assessing the adaptation of a client to changes in functional status after a stroke (brain attack). Which observation indicates to the nurse that the client is adapting **most** successfully?
   1. Gets angry with family if they interrupt a task
   2. Experiences bouts of depression and irritability
   3. Has difficulty with using modified feeding utensils
   4. Consistently uses adaptive equipment in dressing self

9. The nurse is teaching a client with myasthenia gravis about the prevention of myasthenic and cholinergic crises. Which client activity suggests that teaching is **most effective**?
   1. Taking medications as scheduled
   2. Eating large, well-balanced meals
   3. Doing muscle-strengthening exercises
   4. Doing all chores early in the day while less fatigued

10. The nurse is instructing a client with Parkinson's disease about preventing falls. Which client statement reflects a **need for further teaching**?
    1. "I can sit down to put on my pants and shoes."
    2. "I try to exercise every day and rest when I'm tired."

Telegram & Insta: NCLEX_RN_Edu

3. "My son removed all loose rugs from my bedroom."
4. "I don't need to use my walker to get to the bathroom."

11. The nurse has given suggestions to a client with trigeminal neuralgia about strategies to minimize episodes of pain. The nurse determines that the client **needs further teaching** if the client makes which statement?
1. "I will wash my face with cotton pads."
2. "I'll have to start chewing on my unaffected side."
3. "I should rinse my mouth if toothbrushing is painful."
4. "I'll try to eat my food either very warm or very cold."

12. The client is admitted to the hospital with a diagnosis of Guillain-Barré syndrome. Which past medical history finding makes the client **most** at risk for this disease?
1. Meningitis or encephalitis during the last 5 years
2. Seizures or trauma to the brain within the last year
3. Back injury or trauma to the spinal cord during the last 2 years
4. Respiratory or gastrointestinal infection during the previous month

13. A client with Guillain-Barré syndrome has ascending paralysis and is intubated and receiving mechanical ventilation. Which strategy would the nurse incorporate in the plan of care to help the client cope with this illness?
1. Giving client full control over care decisions and restricting visitors
2. Providing positive feedback and encouraging active range of motion
3. Providing information, giving positive feedback, and encouraging relaxation
4. Providing intravenously administered sedatives, reducing distractions, and limiting visitors

14. A client has a neurological deficit involving the limbic system. On assessment, which finding is specific to this type of deficit?
1. Is disoriented to person, place, and time
2. Affect is flat, with periods of emotional lability.
3. Cannot recall what was eaten for breakfast today
4. Demonstrates inability to add and subtract; does not know who is the president of the United States

15. The nurse is instituting seizure precautions for a client who is being admitted from the emergency department. Which measures would the nurse include in planning for the client's safety? **Select all that apply.**
- ❑ 1. Padding the side rails of the bed.
- ❑ 2. Placing an airway at the bedside.
- ❑ 3. Placing the bed in the high position.
- ❑ 4. Putting a padded tongue blade at the head of the bed.
- ❑ 5. Placing oxygen and suction equipment at the bedside.
- ❑ 6. Flushing the intravenous catheter to ensure that the site is patent.

16. The nurse is evaluating the status of a client who had a craniotomy 3 days ago. Which assessment finding would indicate that the client is developing meningitis as a complication of surgery?
1. A negative Kernig's sign
2. Absence of nuchal rigidity
3. A positive Brudzinski's sign
4. A Glasgow Coma Scale score of 15

17. The nurse is admitting a client with Guillain-Barré syndrome to the nursing unit. The client has complaints of inability to move both legs and reports a tingling sensation above the waistline. Knowing the complications of the disorder, the nurse would bring which **most essential** items into the client's room?
1. Nebulizer and pulse oximeter
2. Blood pressure cuff and flashlight
3. Nasal cannula and incentive spirometer
4. Electrocardiographic monitoring electrodes and intubation tray

ANSWERS

1. ***Answer:*** 2
Rationale: Pressure on nail beds tests a basic motor and sensory peripheral response. Cerebral responses to pain are tested using a sternal rub, placing upward pressure on the orbital rim, or squeezing the clavicle or sternocleidomastoid muscle.

Test-Taking Strategy: Focus on the subject, testing peripheral response to pain. The nail beds are the most distal of all options and are therefore the most peripheral. Each of the other options may elicit a generalized response, but not a localized one.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 431-432, 834.

Telegram & Insta: NCLEX_RN_Edu

2. *Answer:* 2
Rationale: A change in vital signs may be a late sign of increased intracranial pressure. Trends include increasing temperature, widening pulse pressure, increased systolic blood pressure, and decreasing pulse and respirations. Respiratory irregularities also may occur.
Test-Taking Strategy: Focus on the **subject,** signs of increased intracranial pressure. If you remember that the temperature rises, you are able to eliminate options 3 and 4. If you know that the client becomes bradycardic or know that the blood pressure rises, you are able to select the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1303-1304.

3. *Answer:* 4
Rationale: Activities that increase intrathoracic and intraabdominal pressures cause an indirect elevation of the intracranial pressure. Some of these activities include isometric exercises, Valsalva's maneuver, coughing, sneezing, and blowing the nose. Exhaling during activities such as repositioning or pulling up in bed opens the glottis, which prevents intrathoracic pressure from rising.
Test-Taking Strategy: Focus on the **subject,** preventing elevations in intracranial pressure. Evaluate each option in terms of the tension it puts on the body. Doing so will help you eliminate each incorrect option systematically.
Reference: Urden, L., Stacy, K., & Lough, M. (2020). *Priorities in critical care nursing.* (8th ed.). St. Louis: Elsevier. p. 319.

4. *Answer:* 4
Rationale: Leakage of cerebrospinal fluid (CSF) from the ears or nose may accompany basilar skull fracture. CSF can be distinguished from other body fluids, because the drainage will separate into bloody and yellow concentric rings on dressing material, called a *halo sign*. The fluid also tests positive for glucose.
Test-Taking Strategy: Focus on the **subject,** the characteristics of CSF. Recall that CSF contains glucose, whereas other secretions, such as mucus, do not. Knowing that CSF separates into rings also will help you answer this question.
Reference: Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 613.

5. *Answer:* 1, 3, 4
Rationale: Nursing actions during a seizure include providing for privacy, loosening restrictive clothing, removing the pillow and raising padded side rails in the bed, and placing the client on one side with the head flexed forward, if possible, to allow the tongue to fall forward and facilitate drainage. The limbs are never restrained because the strong muscle contractions could cause the client harm. If the client is not in bed when seizure activity begins, the nurse lowers the client to the floor, if possible; protects the head from injury; and moves furniture that may injure the client.
Test-Taking Strategy: Focus on the **subject,** interventions during a seizure. Think about ethical and legal issues to eliminate option 5. Next, evaluate this question from the perspective of causing possible harm. No harm can come to the client from any of the options except for restraining the limbs. Remember to avoid restraints.
Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 864-865.

6. *Answer:* 1, 2, 4
Rationale: Hemiparesis is a weakness of one side of the body that may occur after a stroke. It involves weakness of the face and tongue, arm, and leg on one side. These clients are also aphasic, unable to discriminate words and letters. They are generally very cautious and get anxious when attempting a new task. Complete bilateral paralysis does not occur in hemiparesis. The client with right-sided hemiparesis has weakness of the right arm and leg and needs assistance with feeding, bathing, and ambulating.
Test-Taking Strategy: Focus on the **subject,** right-sided hemiparesis. Recalling that hemiparesis indicates weakness on one side of the body and focusing on the **subject** will direct you to the correct option. Also, noting the word *complete* in the question will assist you in answering correctly.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1336-1337.

7. *Answer:* 4
Rationale: Homonymous hemianopsia is loss of half of the visual field. The client with homonymous hemianopsia needs to have objects placed in the intact field of vision, and the nurse also would approach the client from the intact side. The nurse instructs the client to scan the environment to overcome the visual deficit and does client teaching from within the intact field of vision. The nurse encourages the use of personal eyeglasses, if they are available.
Test-Taking Strategy: Focus on the **subject,** homonymous hemianopsia. Eliminate options 2 and 3 first because they are **comparable or alike.** Recalling the definition of homonymous hemianopsia will direct you easily to the correct option.
Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1294, 1316, 1347.

8. *Answer:* 4
Rationale: Clients are evaluated as coping successfully with lifestyle changes after a stroke if they make appropriate lifestyle alterations, use the assistance of others, and have appropriate social interactions. Options 1 and 2 are not adaptive behaviors; option 3 indicates a not yet successful attempt to adapt.
Test-Taking Strategy: Note the **strategic word,** *most,* and focus on the **subject,** indications that a client who has had a stroke is adapting most successfully. Options 1 and 2 are behaviors that may be expected in the client with a stroke, but they are not adaptive responses. Instead, they are a result of the insult to the brain. Options 3 and 4 indicate that the client is trying to adapt, but the correct option has the best outcome.

Telegram & Insta: NCLEX_RN_Edu

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1347-1349.

9. *Answer:* 1

Rationale: Clients with myasthenia gravis are taught to space out activities over the day to conserve energy and restore muscle strength. Taking medications correctly to maintain blood levels that are not too low or too high is important. Muscle-strengthening exercises are not helpful and can fatigue the client. Overeating is a cause of exacerbation of symptoms, as is exposure to heat, crowds, erratic sleep habits, and emotional stress.

Test-Taking Strategy: Note the **strategic words,** *most effective*. Recalling that the common causes of myasthenic and cholinergic crises are undermedication and overmedication, respectively, will assist you in eliminating each of the incorrect options. No other option would prevent both of those complications.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1378-1379.

10. *Answer:* 4

Rationale: The client with Parkinson's disease would be instructed regarding safety measures in the home. The client needs to use a walker as support to get to the bathroom because of bradykinesia. The client would sit down to put on pants and shoes to prevent falling. The client needs to exercise every day in the morning when energy levels are highest. The client needs to have all loose rugs in the home removed to prevent falling.

Test-Taking Strategy: Note the **strategic words,** *need for further teaching*. These words indicate a **negative event query** and the need to select the incorrect client statement as the answer. Recall that clients with Parkinson's disease are at risk for falls.

Reference: Ignatavicius, D., Workman, M., Rebar, C., & Heimgartner, N. (2021). *Medical-surgical nursing: Concepts for interprofessional collaborative care.* (10th ed.). St. Louis: Elsevier. pp. 857, 1040.

11. *Answer:* 4

Rationale: Facial pain can be minimized by using cotton pads to wash the face and using room temperature water. The client needs to chew on the unaffected side of the mouth, eat a soft diet, and take in foods and beverages at room temperature. If brushing the teeth triggers pain, an oral rinse after meals may be helpful instead.

Test-Taking Strategy: Note the **strategic words,** *needs further teaching*. These words indicate a **negative event query** and ask you to select an option that is incorrect. Recall that the pain of trigeminal neuralgia is triggered by mechanical or thermal stimuli. Very hot or cold foods are likely to trigger the pain, not relieve it.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1423.

12. *Answer:* 4

Rationale: Guillain-Barré syndrome is a clinical syndrome of unknown origin that involves cranial and peripheral nerves. Many clients report a history of respiratory or gastrointestinal infection in the 1 to 4 weeks before the onset of neurological deficits. On occasion, the syndrome can be triggered by vaccination or surgery.

Test-Taking Strategy: Note the **strategic word,** *most*. Use knowledge regarding the causes related to this disorder. Remember that a recent history of respiratory or gastrointestinal infection is a predisposing factor.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1424-1425; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 609-610.

13. *Answer:* 3

Rationale: The client with Guillain-Barré syndrome experiences fear and anxiety from the ascending paralysis and sudden onset of the disorder. The nurse can alleviate these fears by providing accurate information about the client's condition, giving expert care and positive feedback to the client, and encouraging relaxation and distraction. The family can become involved with selected care activities and provide diversion for the client as well.

Test-Taking Strategy: Focus on the **subject,** helping a client cope with illness. Option 1 can be eliminated first, because it is not practical to think that the client would want full control over all care decisions. The client who is paralyzed cannot participate in active range of motion, which eliminates option 2. From the remaining options, the correct option is more beneficial in helping the client cope.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1424-1425; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. pp. 609-610.

14. *Answer:* 2

Rationale: The limbic system is responsible for feelings (affect) and emotions. Calculation ability and knowledge of current events relate to function of the frontal lobe. The cerebral hemispheres, with specific regional functions, control orientation. Recall of recent events is controlled by the hippocampus.

Test-Taking Strategy: Focus on the **subject,** neurological deficit of the limbic system. It is necessary to recall that the limbic system is responsible for feelings and emotions to direct you to the correct option.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 78, 1282-1283.

15. *Answer:* 1, 2, 5, 6

Rationale: Seizure precautions may vary from agency to agency, but they generally have some common features.

Telegram & Insta: NCLEX_RN_Edu

Usually, an airway, oxygen, and suctioning equipment are kept available at the bedside. The side rails of the bed are padded, and the bed is kept in the lowest position. The client has an intravenous access in place to have a readily accessible route if antiseizure medications must be administered, and as part of the routine assessment the nurse would be checking patency of the catheter. The use of padded tongue blades is highly controversial, and they would not be kept at the bedside. Forcing a tongue blade into the mouth during a seizure more likely will harm the client who bites down during seizure activity. Risks include blocking the airway from improper placement, chipping the client's teeth, and subsequent risk of aspirating tooth fragments. If the client has an aura before the seizure, it may give the nurse enough time to place an oral airway before seizure activity begins.

Test-Taking Strategy: Focus on the **subject,** seizure precautions. Evaluate this question from the perspective of causing possible harm. No harm can come to the client from any of the options except for placing the bed in the high position and using a tongue blade.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1364-1365.

16. *Answer:* 3

Rationale: Signs of meningeal irritation compatible with meningitis include nuchal rigidity, a positive Brudzinski's sign, and positive Kernig's sign. Nuchal rigidity is characterized by a stiff neck and soreness, which is especially noticeable when the neck is flexed. Kernig's sign is positive when the client feels pain and spasm of the hamstring muscles when the leg is fully flexed at the knee and hip. Brudzinski's sign is positive when the client flexes the hips and knees in response to the nurse gently flexing the head and neck onto the chest. A Glasgow Coma Scale score of 15 is a perfect score and indicates that the client is awake and alert, with no neurological deficits.

Test-Taking Strategy: Focus on the **subject,** a client's diagnosis of meningitis. You can eliminate options 1, 2, and 4 because they are **comparable or alike** and are normal findings.

Reference: Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology.* (7th ed.). St. Louis: Elsevier. pp. 399-401, 422.

17. *Answer:* 4

Rationale: The client with Guillain-Barré syndrome is at risk for respiratory failure because of ascending paralysis. An intubation tray needs to be available for use. Another complication of this syndrome is cardiac dysrhythmias, which necessitates the use of electrocardiographic monitoring. Because the client is immobilized, the nurse needs to assess for deep vein thrombosis and pulmonary embolism routinely. Although items in the incorrect options may be used in care, they are not the most essential items from the options provided.

Test-Taking Strategy: Note the **strategic words,** *most essential*. With an ascending paralysis, the client is at risk for involvement of respiratory muscles and subsequent respiratory failure. The correct option is the only one that includes an intubation tray, which would be needed if the client's status deteriorated to needing intubation and mechanical ventilation. This option most directly addresses the airway.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. pp. 1424-1425; Urden, L., Stacy, K., & Lough, M. (2022). *Critical care nursing: Diagnosis and management.* (9th ed.). St. Louis: Elsevier. p. 610.

CHAPTER 60

Neurological Medications

Contributors: David Petersen, MSN-Ed, RN
James Guilbault, PharmD, BS, RPh

PRIORITY CONCEPTS **Intracranial Regulation; Pain**

I. Antimyasthenic Medications

A. Description

1. Antimyasthenic medications, also called *anticholinesterase medications,* relieve muscle weakness associated with myasthenia gravis by blocking acetylcholine breakdown at the neuromuscular junction.
2. These are used to treat or diagnose myasthenia gravis or to distinguish cholinergic crisis from myasthenic crisis.
3. Neostigmine bromide and pyridostigmine are used to control myasthenic symptoms.
4. Edrophonium is used to diagnose myasthenia gravis and to distinguish cholinergic crisis from myasthenic crisis.

B. Medications (Box 60.1)

C. Side and adverse effects: Cholinergic crisis (Box 60.2)

D. Interventions

1. Assess neuromuscular status, including reflexes, muscle strength, and gait.
2. Monitor the client for signs and symptoms of medication overdose (cholinergic crisis) and underdose (myasthenic crisis).
3. Instruct the client to take medications on time to maintain therapeutic blood level, thus preventing weakness, because weakness can impair the client's ability to breathe and swallow.
4. Instruct the client to take the medication with a small amount of food to prevent gastrointestinal symptoms.
5. Instruct the client to eat a meal 45 to 60 minutes after taking medications to decrease the risk for aspiration.
6. Instruct the client to wear a MedicAlert bracelet.
7. Note that antimyasthenic therapy is lifelong therapy.
8. Evaluate for medication effectiveness, which is based on the improvement of neuromuscular symptoms or strength without cholinergic signs and symptoms.
9. When administering edrophonium, have emergency resuscitation equipment on hand and atropine sulfate available for cholinergic crisis.

II. Multiple Sclerosis Medications

A. Description

1. Medication therapy is aimed at modifying the disease, treating acute episodes or relapses, and treating symptoms.
2. Disease-modifying medications decrease the frequency and severity of relapses, reduce brain lesions, increase future functional capability, and increase overall quality of life.
3. The two main groups of disease-modifying medications are immunomodulators and immunosuppressants (Box 60.3).
4. Treating acute episodes usually consists of giving a high-dose glucocorticoid intravenously to suppress inflammation or giving gamma globulin intravenously.
5. Treating symptoms of multiple sclerosis can be done with a variety of medications, and the medication can be changed if unfavorable effects occur.
6. Box 60.4 identifies medications commonly used to treat symptoms.

B. Side and adverse effects

1. Immunomodulators: Flulike reactions, hepatotoxicity, myelosuppression, injection site reactions, depression, and neutralizing antibodies
2. Immunosuppressants: Myelosuppression, cardiotoxicity, fetal harm, reversible hair loss, injury to the gastrointestinal mucosa, nausea and vomiting, and menstrual irregularities

Telegram & Insta: NCLEX_RN_Edu

BOX 60.1 Antimyasthenic Medications

- Neostigmine bromide
- Pyridostigmine

BOX 60.2 Signs of Cholinergic Crisis

- Abdominal cramps
- Blurred vision
- Bronchospasm, wheezing, and bradycardia
- Facial muscle twitching
- Hypotension
- Increased bronchial secretions, tearing, perspiration
- Nausea, vomiting, and diarrhea
- Pallor
- Pupillary miosis

III. Antiparkinsonian Medications

A. Description

1. Antiparkinsonian medications restore the balance of the neurotransmitters acetylcholine and dopamine in the central nervous system (CNS), decreasing the signs and symptoms of Parkinson's disease to maximize the client's functional abilities.

2. These medications include the dopaminergics, which stimulate the dopamine receptors; the anticholinergics, which block the cholinergic receptors; and the catechol-*O*-methyltransferase inhibitors, which inhibit the metabolism of dopamine in the periphery.

B. Dopaminergic medications

1. Description

a. Dopaminergic medications stimulate the dopamine receptors and increase the amount of dopamine available in the CNS or enhance neurotransmission of dopamine.

b. Dopaminergic medications are contraindicated in clients with cardiac, renal, or psychiatric disorders.

⚠ Carbidopa-levodopa taken with a monoamine oxidase inhibitor antidepressant can cause a hypertensive crisis.

2. Medications (Box 60.5)

3. Side and adverse effects

a. Dyskinesia

b. Involuntary body movements

c. Chest pain

d. Nausea and vomiting

e. Urinary retention

f. Constipation

g. Sleep disturbances, insomnia, or periods of sedation

h. Orthostatic hypotension and dizziness

BOX 60.3 Medications for Multiple Sclerosis

Immunomodulators

Interferons (β-1a, 1b, peginterferon β-1a)
Cladribine
Dimethyl fumarate
Fingolimod
Glatiramer acetate
Teriflunomide

Immunosuppressant

Mitoxantrone

Monoclonal antibodies

Alemtuzumab
Natalizumab
Ocrelizumab
Ofatumumab

Glucocorticoids

Methylprednisolone
Prednisone

BOX 60.4 Medications to Treat Symptoms of Multiple Sclerosis

- Bladder and bowel dysfunction: psyllium, docusate
- Cognitive dysfunction: memantine
- Depression: fluoxetine, sertraline
- Fatigue: amantadine, modafinil
- Neuropathic pain: gabapentin, carbamazepine
- Sexual dysfunction: sildenafil, vardenafil
- Walking speed: dalfampridine

Adapted from Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 215-216.

BOX 60.5 Medications to Treat Parkinson's Disease

Medications Affecting the Amount of Dopamine

- Amantadine
- Apomorphine
- Bromocriptine
- Carbidopa-levodopa
- Pramipexole
- Rasagiline
- Ropinirole
- Rotigotine
- Safinamide
- Selegiline hydrochloride

Anticholinergics

- Benztropine mesylate
- Trihexyphenidyl hydrochloride

Catechol-*O*-Methyltransferase (COMT) Inhibitors

- Carbidopa/levodopa/entacapone
- Entacapone
- Opicapone
- Tolcapone

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

i. Confusion
j. Mood changes, especially depression
k. Hallucinations
l. Dry mouth

4. Interventions
   a. Assess vital signs.
   b. Assess for risk of injury.
   c. Instruct the client to take the medication with food if nausea or vomiting occurs.
   d. Assess for signs and symptoms of parkinsonism such as rigidity, tremors, akinesia, bradykinesia, a stooped forward posture, shuffling gait, and masked facies.
   e. Monitor for signs of dyskinesia.
   f. Instruct the client to report side and adverse effects and symptoms of dyskinesia.
   g. Monitor the client for improvement in signs and symptoms of parkinsonism.
   h. Instruct the client to change positions slowly to minimize orthostatic hypotension.
   i. Instruct the client not to discontinue the medication abruptly.
   j. Instruct the client to avoid alcohol.
   k. Inform the client that urine or perspiration may be discolored and that this is harmless but may stain the clothing.
   l. Advise the client with **diabetes mellitus** that glucose testing should not be done by urine testing, because the results will not be reliable.
   m. Instruct the client taking carbidopa-levodopa to divide the total daily prescribed protein intake among all meals of the day; high-protein diets interfere with medication availability to the CNS.
   n. When administering carbidopa-levodopa, instruct the client to avoid excessive vitamin B_6 intake and prepare to regularly check vitamin B_6 levels per PHCP recommendations to prevent medication reactions.

C. Anticholinergic medications
1. Description
   a. Anticholinergic medications block the cholinergic receptors in the CNS, thereby suppressing acetylcholine activity.
   b. They reduce the tremors and drooling but have a minimal effect on the bradykinesia, rigidity, and balance abnormalities.
   c. They are contraindicated in clients with glaucoma.
   d. The client with chronic obstructive lung disease can develop dry, thick mucous secretions.
2. Medications (see Box 60.5)
3. Side and adverse effects
   a. Blurred vision
   b. Dryness of the nose, mouth, throat, and respiratory secretions
   c. Increased pulse rate, palpitations, and dysrhythmias
   d. Constipation
   e. Urinary retention
   f. Restlessness, confusion, depression, and hallucinations
   g. Photophobia
4. Interventions
   a. Monitor vital signs.
   b. Assess for risk of injury.
   c. Monitor the client for improvement in signs and symptoms.
   d. Assess the client's bowel and urinary function and monitor for urinary retention, constipation, and paralytic ileus.
   e. Monitor for involuntary movements.
   f. Encourage the client to avoid alcohol, smoking, caffeine, and acetylsalicylic acid to decrease gastric acidity.
   g. Instruct the client to consult with a primary health care provider (PHCP) before taking any nonprescription medications.
   h. Instruct the client to minimize dry mouth by increasing fluid intake and using ice chips, sugarless hard candy, or gum.
   i. Instruct the client to prevent constipation by increasing fluids and fiber in the diet.
   j. Instruct the client to use sunglasses in direct sunlight because of possible photophobia.
   k. Instruct the client to have routine eye examinations to assess intraocular pressure.

If an anticholinergic medication is discontinued abruptly, the signs and symptoms of parkinsonism, such as rigidity, tremors, akinesia, bradykinesia, stooped forward posture, shuffling gait, and masked facies, may be intensified.

IV. Antiseizure Medications

A. Description
1. Antiseizure medications are used to depress abnormal neuronal discharges and prevent the spread of seizures to adjacent neurons.
2. These should be used with caution in clients taking anticoagulants, acetylsalicylic acid, sulfonamides, cimetidine, and antipsychotic medications.
3. Absorption is decreased with the use of antacids, calcium preparations, and antineoplastic medications.

B. Interventions for clients on antiseizure medications
1. Initiate seizure precautions.
2. Monitor urinary output.
3. Monitor liver and renal function tests and medication blood serum levels (Table 60.1).
4. Monitor for signs of medication toxicity, which would include CNS depression, ataxia, nausea, vomiting, drowsiness, dizziness, restlessness, and visual disturbances.

Telegram & Insta: NCLEX_RN_Edu

TABLE 60.1 Common Antiseizure Medications

Medication	Therapeutic Serum Range
Carbamazepine	3-14 mcg/mL
Clonazepam	20-80 ng/mL
Divalproex	50-100 mcg/mL
Ethosuximide	40-100 mcg/mL
Lorazepam	50-240 ng/mL
Phenobarbital	15-40 mcg/mL
Phenytoin	10-20 mcg/mL

BOX 60.6 Client Education: Antiseizure Medications

- Take the prescribed medication in the prescribed dose and frequency.
- Promote client adherence to prescribed regimen; do not discontinue the medications.
- Take with food to decrease gastrointestinal irritation, but avoid milk and antacids, which impair absorption.
- If taking liquid medication, shake well before ingesting.
- Avoid alcohol.
- Avoid over-the-counter medications.
- Wear a MedicAlert bracelet.
- Use caution when performing activities that require alertness.
- Maintain good oral hygiene and use a soft toothbrush.
- Maintain preventive dental checkups.
- Maintain follow-up health care visits with periodic blood studies related to determining toxicity.
- Monitor serum glucose levels (diabetes mellitus).
- Urine may be a harmless pink-red or red-brown color.
- Report symptoms of sore throat, bruising, and nosebleeds, which may indicate a blood dyscrasia.
- Inform the primary health care provider if side and adverse effects occur, such as bleeding gums, nausea, vomiting, blurred vision, slurred speech, rash, or dizziness.

5. If a seizure occurs, assess seizure activity, including location and duration (see Chapter 59 for management of seizures).
6. Protect the client from hazards in the environment during a seizure.

C. Client education (Box 60.6)

D. Hydantoins: Fosphenytoin, phenytoin
1. Hydantoins are used to treat partial and generalized tonic-clonic seizures.
2. Phenytoin is also used to treat dysrhythmias.
3. Side and adverse effects
   a. Sedation and drowsiness
   b. Gingival hyperplasia (reddened gums that bleed easily)
   c. Slurred speech
   d. Confusion
   e. Nausea and vomiting
   f. Blurred vision and nystagmus
   g. Headaches
   h. Blood dyscrasias: Decreased platelet count and decreased white blood cell count
   i. Elevated blood glucose level
   j. Alopecia or hirsutism
   k. Rash or pruritus
   l. Teratogenic: Phenytoin crosses the placenta and can cause birth defects and bleeding tendencies in newborns.
4. Interventions
   a. Tube feedings may interfere with the absorption of the enteral form of phenytoin and diminish the effectiveness of the medication; therefore, feedings should be scheduled as far as possible away from the time of phenytoin administration.
   b. Monitor therapeutic serum levels to assess for toxicity.
   c. Monitor for signs of toxicity.
   d. When administering phenytoin intravenously, dilute in normal saline, because dextrose causes the medication to precipitate.
   e. When administering phenytoin intravenously, infuse with an inline filter and no faster than 25 to 50 mg/minute; otherwise, a decrease in blood pressure and cardiac dysrhythmias could occur.
   f. Assess for ataxia (staggering gait).
   g. Instruct the client to consult with the PHCP before taking other medications to ensure compatibility with anticonvulsants.

Intravenous phenytoin must be given slowly to prevent hypotension and cardiac dysrhythmias. Also, phenytoin may decrease the effectiveness of some birth control pills and may cause teratogenic effects, if taken during pregnancy.

E. Barbiturates: Amobarbital, phenobarbital
1. Barbiturates are used for tonic-clonic seizures and acute episodes of seizures caused by status epilepticus.
2. Barbiturates also may be used as adjuncts to anesthesia.
3. Side and adverse effects
   a. Sedation, ataxia, and dizziness during initial treatment
   b. Mood changes
   c. Hypotension
   d. Respiratory depression
   e. Tolerance to the medication

F. Benzodiazepines: Clonazepam, clorazepate, diazepam, lorazepam
1. Benzodiazepines are used to treat absence seizures.
2. Diazepam and lorazepam are used to treat status epilepticus, anxiety, and skeletal muscle spasms.

Telegram & Insta: NCLEX_RN_Edu

3. Clorazepate is used as adjunctive therapy for partial seizures.
4. Side and adverse effects
   a. Sedation, drowsiness, dizziness, blurred vision
   b. For intravenous injection, administer slowly to prevent bradycardia.
   c. Medication tolerance and dependency
   d. Blood dyscrasias: Decreased platelet count and decreased white blood cell count
   e. Hepatotoxicity

⚠ Flumazenil reverses the effects of benzodiazepines. It should not be administered to clients with increased intracranial pressure or status epilepticus who were treated with benzodiazepines, because these problems may recur with reversal.

G. Succinimides: Ethosuximide, methsuximide
1. Succinimides are used to treat absence seizures.
2. Side and adverse effects
   a. Anorexia, nausea, vomiting
   b. Blood dyscrasias

H. Valproates: Valproic acid, divalproex sodium
1. Valproates are used to treat tonic-clonic, partial, and myoclonic seizures.
2. Side and adverse effects
   a. Transient nausea, vomiting, and indigestion
   b. Sedation, drowsiness, and dizziness
   c. Pancreatitis
   d. Blood dyscrasias: Decreased platelet count and decreased white blood cell count
   e. Hepatotoxicity
   f. Teratogenic: Can result in congenital malformation and neural tube defects

I. Iminostilbenes
1. Iminostilbenes are used to treat seizure disorders that have not responded to other anticonvulsants (Box 60.7).
2. Iminostilbenes are also used to treat trigeminal neuralgia.
3. Side and adverse effects
   a. Drowsiness
   b. Dizziness
   c. Nausea and vomiting, dry mouth
   d. Constipation or diarrhea
   e. Rash
   f. Visual abnormalities
   g. Blood dyscrasias, agranulocytosis
   h. Headache

V. Central Nervous System Stimulants

A. Description
1. Amphetamines and caffeine stimulate the cerebral cortex of the brain (Box 60.8).
2. Amphetamines have a high potential for abuse.
3. Analeptics and caffeine act on the brainstem and medulla to stimulate respiration.

BOX 60.7 Other Antiseizure Medications

- Carbamazepine
- Gabapentin
- Lacosamide
- Lamotrigine
- Levetiracetam
- Oxcarbazepine
- Pregabalin
- Tiagabine
- Topiramate
- Vigabatrin
- Zonisamide

BOX 60.8 Amphetamines

- Amphetamine sulfate
- Amphetamine/dextroamphetamine
- Atomoxetine
- Dextroamphetamine sulfate
- Dexmethylphenidate
- Lisdexamfetamine
- Methylphenidate hydrochloride

BOX 60.9 Anorexiants

- Benzphetamine hydrochloride
- Bupropion/naltrexone
- Diethylpropion
- Lorcaserin
- Orlistat
- Phendimetrazine
- Phentermine hydrochloride
- Phentermine/topiramate

4. Anorexiants act on the cerebral cortex and hypothalamus to suppress appetite (Box 60.9).
5. CNS stimulants are used to treat narcolepsy and attention-deficit/hyperactivity disorders and are used as adjunctive therapy for exogenous obesity.

B. Side and adverse effects
1. Irritability
2. Restlessness
3. Tremors
4. Insomnia
5. Heart palpitations
6. Tachycardia and dysrhythmias
7. Hypertension
8. Dry mouth
9. Anorexia and weight loss
10. Abdominal cramping
11. Diarrhea or constipation
12. Hepatic failure
13. Psychoses
14. Impotence
15. Dependence and tolerance

Telegram & Insta: NCLEX_RN_Edu

C. Interventions

1. Monitor vital signs.
2. Assess mental status.
3. Document the degree of inattention, impulsivity, hyperactivity, and periods of sleepiness.
4. Assess height, weight, and growth of the child.
5. Monitor complete blood count and white blood cell and platelet counts before and during therapy.
6. Monitor for side and adverse effects.
7. Monitor sleep patterns.
8. Monitor for withdrawal symptoms such as nausea, vomiting, weakness, and headache.
9. Instruct the client to take the medication before meals.
10. Instruct the client to avoid foods and beverages containing caffeine to prevent additional stimulation.
11. Instruct the client not to chew or crush long-acting forms of the medications.
12. Instruct the client to read labels on over-the-counter products, because they may contain caffeine.
13. Instruct the client to avoid alcohol.
14. Instruct the client not to discontinue the medication abruptly (can produce extreme fatigue and depression).
15. Instruct the client to take the last daily dose of the CNS stimulant at least 6 hours before bedtime to prevent insomnia.
16. Monitor for medication dependence and abuse with amphetamines.
17. If a child is taking a CNS stimulant, instruct the parents to notify the school nurse.
18. Monitor for calming effects of CNS stimulants within 3 to 4 weeks in children with attention-deficit/hyperactivity disorder.
19. Monitor growth in the child on long-term therapy with methylphenidate or other medications to treat attention-deficit/hyperactivity disorder.

VI. Nonopioid Analgesics

A. Nonsteroidal antiinflammatory drugs (NSAIDs; Box 60.10)

1. Description
   - **a.** NSAIDs are acetylsalicylic acid and acetylsalicylic acid–like medications that inhibit the synthesis of prostaglandins.
   - **b.** The medications act as an analgesic to relieve pain, an antipyretic to reduce body temperature, and an anticoagulant to inhibit platelet aggregation.
   - **c.** NSAIDs are used to relieve inflammation and pain and to treat rheumatoid arthritis, bursitis, tendinitis, osteoarthritis, and acute gout.

BOX 60.10 Nonopioid Analgesics

Acetaminophen

Aspirin
- Aspirin (acetylsalicylic acid; ASA)
- Aspirin (acetylsalicylic acid), buffered

Nonsteroidal Antiinflammatory Drugs
- Ibuprofen
- Naproxen

Cyclooxygenase-2 (COX-2) Inhibitor
- Celecoxib

Other Nonsteroidal Antiinflammatory Drugs
- Diclofenac
- Diflunisal
- Etodolac
- Flurbiprofen
- Indomethacin
- Ketoprofen
- Ketorolac
- Meclofenamate
- Mefenamic acid
- Meloxicam
- Nabumetone
- Oxaprozin
- Piroxicam
- Sulindac
- Tolmetin

   - **d.** NSAIDs are contraindicated in clients with hypersensitivity or liver or renal disease.
   - **e.** Clients taking anticoagulants should not take acetylsalicylic acid or NSAIDs.
   - **f.** Acetylsalicylic acid and an NSAID should not be taken together, because aspirin decreases the blood level and effectiveness of the NSAID and can increase the risk of bleeding.
   - **g.** NSAIDs can increase the effects of warfarin, sulfonamides, cephalosporins, and phenytoin.
   - **h.** Hypoglycemia can result if ibuprofen is taken with insulin or an oral hypoglycemic medication.
   - **i.** A high risk of toxicity exists if ibuprofen is taken concurrently with calcium channel blockers.

! Adolescents and children with flu symptoms, viral illnesses, and varicella should not take acetylsalicylic acid because of the risk of Reye's syndrome.

2. Side and adverse effects (Box 60.11)
3. Interventions
   - **a.** Assess client for allergies.
   - **b.** Obtain a medication history on the client.

Telegram & Insta: NCLEX_RN_Edu

BOX 60.11 Side and Adverse Effects of Acetylsalicylic Acid and Nonsteroidal Antiinflammatory Drugs

Acetylsalicylic acid

- Allergic reactions (anaphylaxis, laryngeal edema)
- Bleeding (anemia, hemolysis, increased bleeding time)
- Decreased renal function
- Dizziness
- Drowsiness
- Flushing
- Gastrointestinal symptoms (distress, heartburn, nausea, vomiting)
- Headaches
- Tinnitus
- Visual changes

Nonsteroidal Antiinflammatory Drugs

- Blood dyscrasias
- Cardiovascular thrombotic events
- Decreased renal function
- Dizziness
- Dysrhythmias
- Gastric irritation
- Hepatotoxicity
- Hypotension
- Pruritus
- Sodium and water retention
- Tinnitus

c. Assess for history of gastric upset or bleeding or liver or renal disease.
d. Assess the client for gastrointestinal upset during medication administration.
e. Monitor for edema.
f. Monitor the serum salicylate (acetylsalicylic acid) level when the client is taking high doses.
g. Monitor for signs of bleeding such as tarry stools, bleeding gums, petechiae, ecchymosis, and purpura.
h. Instruct the client to take the medication with milk or food.
i. An enteric-coated or buffered form of acetylsalicylic acid can be taken to decrease gastric distress.
j. Instruct the client that enteric-coated tablets cannot be crushed or broken.
k. Clients taking acetylsalicylic acid should sit upright for 20 to 30 minutes after taking the dose.
l. Advise clients to inform other health care professionals if they are taking high doses of acetylsalicylic acid.
m. Note that acetylsalicylic acid should be discontinued 3 to 7 days before surgery as prescribed to reduce the risk of bleeding.
n. Instruct the client to avoid alcoholic beverages.

B. Acetaminophen
1. Description
   a. Acetaminophen inhibits prostaglandin synthesis.
   b. Used to decrease pain and fever
   c. Should not be taken if liver dysfunction exists
2. Side and adverse effects
   a. Anorexia, nausea, vomiting
   b. Rash
   c. Hypoglycemia
   d. Oliguria
   e. Hepatotoxicity (risk of liver injury when ingesting more than 4000 mg per day)
3. Interventions
   a. Monitor vital signs.
   b. Assess client for history of liver and renal dysfunction, alcoholism, and malnutrition.
   c. Monitor for hepatic damage, which includes nausea, vomiting, diarrhea, and abdominal pain.
   d. Monitor liver enzyme test results.
   e. Instruct the client that self-medication should not be used longer than 10 days for an adult and 5 days for a child.
   f. Note that the antidote for acetaminophen is acetylcysteine.
   g. Evaluate for the effectiveness of the medication.

⚠ Acetaminophen is contraindicated in clients with hepatic or renal disease, alcoholism, and/or hypersensitivity.

VII. Opioid Analgesics

A. Description
1. Opioid analgesics suppress pain impulses but can suppress respiration and coughing by acting on the respiratory and cough center in the medulla of the brainstem.
2. They can produce euphoria and sedation and can cause physical dependence.
3. Used for relief of mild, moderate, or severe pain
4. Opioid analgesics carry an increased risk of respiratory depression, a high potential for abuse and overdose, risk for constipation, and increased risk of nausea and vomiting (see Chapter 67 for more information on opioid dependence, abuse, and overdose).

B. Medications (Box 60.12)

C. Opioid Analgesics (see Clinical Judgment: Take Action Box)
1. Side and adverse effects
   a. Respiratory depression
   b. Orthostatic hypotension
   c. Urinary retention
   d. Nausea and vomiting
   e. Constipation

Telegram & Insta: NCLEX_RN_Edu

BOX 60.12 Opioid Analgesics

- Codeine sulfate
- Hydromorphone
- Fentanyl
- Methadone
- Morphine sulfate
- Opioid agonist-antagonist: buprenorphine with naloxone
- Oxycodone; acetaminophen (combination product)
- Oxymorphone
- Tapentadol

f. Sedation, confusion, and hallucinations
g. Cough suppression
h. Reduction in pupillary size
i. Miosis

D. Interventions for opioid analgesics

1. Monitor vital signs. Per PHCP orders, administer antiemetic prior to opioid administration to prevent nausea and vomiting where appropriate.
2. Assess the client thoroughly before administering pain medication.
3. Initiate nursing measures such as massage, distraction, deep breathing and relaxation exercises, the application of heat or cold as prescribed, and providing care and comfort along with administering the opioid analgesic.
4. Administer medications 30 to 60 minutes before painful activities.
5. Monitor respiratory rate. If the rate is less than 12 breaths per minute in an adult, withhold the medication unless ventilatory support is being provided or the client has terminal disease (as prescribed).
6. Monitor pulse; if bradycardia develops, withhold the dose and notify the PHCP.
7. Monitor blood pressure for hypotension.
8. Auscultate breath sounds, because opioid analgesics can suppress the cough reflex.
9. Encourage activities such as turning, deep breathing, and incentive spirometry to prevent atelectasis and pneumonia.
10. Monitor level of consciousness.
11. Initiate safety precautions such as a night-light and supervised ambulation.
12. Monitor intake and output.
13. Assess for urinary retention.
14. Instruct the client to take oral doses with milk or a snack to reduce gastric irritation.
15. Instruct the client to avoid alcohol.
16. Instruct the client to avoid activities that require alertness.
17. Assess bowel function for constipation, abdominal distention, and decreased peristalsis.
18. Evaluate the effectiveness of medication.
19. Have an opioid antagonist (such as naloxone), oxygen, and resuscitation equipment available.

CLINICAL JUDGMENT: TAKE ACTION

A client with a traumatic brain injury experiencing restlessness and agitation because of pain is receiving morphine sulfate. On assessment of the client the nurse measures the respiratory rate and notes it to be 10 breaths/min. The nurse takes the following actions:

- Withholds the morphine sulfate
- Stays with the client
- Monitors pulse oximetry reading and vital signs frequently, especially respirations
- Administers oxygen
- Administers naloxone per protocol prescription
- Contacts the primary health care provider
- Documents assessment findings and actions taken

BOX 60.13 Opioid Antagonists

- Alvimopan
- Methylnaltrexone
- Naldemedine
- Naloxegol
- Naloxone
- Naltrexone

VIII. Opioid Antagonists

A. Opioid antagonists (Box 60.13) are used to treat respiratory depression from opioid overdose.

B. Interventions

1. Monitor blood pressure, pulse, and respiratory rate every 5 minutes initially, tapering to every 15 minutes, and then every 30 minutes until the client is stable.
2. Place the client on a cardiac monitor, and monitor cardiac rhythm.
3. Auscultate breath sounds.
4. Have resuscitation equipment available.
5. Do not leave the client unattended.
6. Monitor the client closely for several hours, because when the effects of the antagonist wear off, the client may again display signs of opioid overdose due to a short half-life.

IX. Osmotic Diuretics

A. Description

1. Osmotic diuretics increase osmotic pressure of the glomerular filtrate, inhibiting reabsorption of water and electrolytes.
2. They are used for **oliguria** and to prevent kidney failure, decrease ICP, and decrease intraocular pressure in clients with narrow-angle glaucoma.
3. Mannitol is used with chemotherapy to induce diuresis.

Telegram & Insta: NCLEX_RN_Edu

B. Side and adverse effects
1. Fluid and electrolyte imbalances
2. Pulmonary edema from the rapid shifts of fluid
3. Nausea and vomiting
4. Headache
5. Tachycardia from the rapid fluid loss
6. Hyponatremia and dehydration

C. Interventions
1. Monitor vital signs.
2. Monitor weight.
3. Monitor urine output.
4. Monitor electrolyte levels.
5. Monitor lungs and heart sounds for signs of pulmonary edema.
6. Monitor for signs of dehydration.
7. Monitor neurological status.
8. Monitor for increased intraocular pressure.
9. Assess for signs of decreasing ICP if appropriate.
10. Change the client's position slowly to prevent orthostatic hypotension.
11. Monitor for crystallization in the vial of mannitol before administering the medication; if crystallization is noted, do not administer the medication from that vial.

PRACTICE QUESTIONS

1. Carbidopa-levodopa is prescribed for a client with Parkinson's disease. The nurse monitors the client for side and adverse effects of the medication. Which finding indicates that the client is experiencing an adverse effect?
1. Pruritus
2. Tachycardia
3. Hypertension
4. Impaired voluntary movements

2. The home health nurse visits a client who is taking phenytoin for control of seizures. During the assessment, the nurse notes that the client is taking birth control pills. Which information would the nurse include in the teaching plan?
1. Pregnancy must be avoided while taking phenytoin.
2. The client may stop the medication if it is causing severe gastrointestinal effects.
3. There is the potential of decreased effectiveness of birth control pills while taking phenytoin.
4. There is the increased risk of thrombophlebitis while taking phenytoin and birth control pills together.

3. The nurse is caring for a client in the emergency department who has been diagnosed with Bell's palsy. The client has been taking acetaminophen, and acetaminophen overdose is suspected. Which antidote would the nurse prepare for administration if prescribed?
1. Pentostatin
2. Auranofin
3. Fludarabine
4. Acetylcysteine

4. Oxycodone has been prescribed for a client to treat pain. Which side and adverse effects would the nurse monitor for? **Select all that apply.**
- ❑ 1. Diarrhea
- ❑ 2. Tremors
- ❑ 3. Drowsiness
- ❑ 4. Hypotension
- ❑ 5. Urinary frequency
- ❑ 6. Increased respiratory rate

5. A client is taking the prescribed dose of phenytoin to control seizures. Results of a phenytoin blood level study reveal a level of 35 mcg/mL. Which finding would be expected as a result of this laboratory result?
1. Hypotension
2. Tachycardia
3. Slurred speech
4. No abnormal finding

6. The client arrives at the emergency department, complaining of back spasms. The client states, "I have been taking 2 to 3 aspirin every 4 hours for the last week, and it hasn't helped my back." Since acetylsalicylic acid intoxication is suspected, the nurse would assess the client for which manifestation?
1. Tinnitus
2. Diarrhea
3. Constipation
4. Photosensitivity

7. A client with trigeminal neuralgia is being treated with carbamazepine, 400 mg orally daily. Which value indicates that the client is experiencing an adverse effect to the medication?
1. Sodium level, 140 mEq/L (140 mmol/L)
2. Uric acid level, 4.0 mg/dL (240 mcmol/L)
3. White blood cell count, 3000 mm^3 (3.0×10^9/L)
4. Blood urea nitrogen level, 10 mg/dL (3.6 mmol/L)

8. The nurse is caring for a client with cancer. Morphine has been prescribed for the client. Specific to this medication, which intervention would the nurse include in the plan of care while the client is taking this medication?
1. Monitor radial pulse.
2. Monitor bowel activity.
3. Monitor apical heart rate.
4. Monitor peripheral pulses.

Telegram & Insta: NCLEX_RN_Edu

9. The nurse has given medication instructions to a client receiving phenytoin. Which statement indicates that the client has an adequate understanding of the instructions?
   1. "Alcohol is not contraindicated while taking this medication."
   2. "Good oral hygiene is needed, including brushing and flossing."
   3. "The medication dose may be self-adjusted, depending on side effects."
   4. "The morning dose of the medication needs to be taken before a medication level is drawn."

10. A client with myasthenia gravis has become increasingly weaker. The primary health care provider prepares to identify whether the client is reacting to an overdose of the medication (cholinergic crisis) or an increasing severity of the disease (myasthenic crisis). An injection of edrophonium is administered. Which finding would indicate that the client is in cholinergic crisis?
    1. No change in the condition
    2. Complaints of muscle spasms
    3. An improvement of the weakness
    4. A temporary worsening of the condition

11. A client with trigeminal neuralgia tells the nurse that acetaminophen is taken daily for the relief of generalized discomfort. Which laboratory value would indicate toxicity associated with the medication?
    1. Sodium level of 140 mEq/L (140 mmol/L)
    2. Platelet count of 400,000 mm^3 (400 × 10^9/L)
    3. Prothrombin time of 12 seconds (12 seconds)
    4. Direct bilirubin level of 2 mg/dL (34 mcmol/L)

ANSWERS

1. *Answer:* 4

Rationale: Dyskinesia and impaired voluntary movements may occur with high carbidopa-levodopa dosages. Nausea, anorexia, dizziness, orthostatic hypotension, bradycardia, and akinesia are frequent side effects of the medication.

Test-Taking Strategy: Focus on the **subject,** an adverse effect. Options 2 and 3 are **comparable or alike** and are cardiac-related options, so these options can be eliminated first. Next, focus on the client's diagnosis and select the correct option over option 1 because it relates to the neurological system.

Reference: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1374.

2. *Answer:* 3

Rationale: Phenytoin enhances the rate of estrogen metabolism, which can decrease the effectiveness of some birth control pills. Options 1, 2, and 4 are inappropriate instructions. Pregnancy does not need to be "avoided" while taking phenytoin; however, because phenytoin may cause some risk to the fetus, consultation with the primary health care provider needs to be done if pregnancy is considered. Telling a client that there is an increased risk of thrombophlebitis is incorrect and inappropriate and could cause anxiety in the client. A client would not be instructed to stop antiseizure medication.

Test-Taking Strategy: Focus on the **subject**, teaching points for the client taking phenytoin. Eliminate option 1 because of the words *must be avoided*. Use general medication guidelines to eliminate option 2; the client would not be advised to stop a medication. For the remaining options, eliminate option 4, as it will cause anxiety in the client.

Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. p. 247.

3. *Answer:* 4

Rationale: The antidote for acetaminophen is acetylcysteine. The normal therapeutic serum level of acetaminophen is 10 to 20 mcg/mL. A toxic level is higher than 50 mcg/mL, and levels higher than 200 mcg/mL 4 hours after ingestion indicate that there is risk for liver damage. Auranofin is a gold preparation that may be used to treat rheumatoid arthritis. Pentostatin and fludarabine are antineoplastic agents.

Test-Taking Strategy: Eliminate options 1 and 3 first because they are **comparable or alike** (antineoplastic agents). Recalling that auranofin is used to treat rheumatoid arthritis will direct you to the correct option.

Reference: Skidmore-Roth, L. (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. pp. 18-19.

4. *Answer:* 2, 3, 4

Rationale: Oxycodone is an opioid analgesic. Side and adverse effects include respiratory depression, drowsiness, hypotension, constipation, urinary retention, nausea, vomiting, and tremors. These effects are potentially life-threatening and therefore are important for the client to be aware of so that they can be reported immediately if noticed.

Test-Taking Strategy: Note the **subject,** side and adverse effects of oxycodone. Recalling that this medication is an opioid analgesic and recalling the effects of an opioid analgesic will assist you in identifying the correct options.

References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 114; Skidmore-Roth, L., (2021). *2021 Mosby's nursing drug reference.* (34th ed.). St. Louis: Elsevier. p. 807.

5. *Answer:* 3

Rationale: The therapeutic phenytoin level is 10 to 20 mcg/mL. At a level higher than 20 mcg/mL, involuntary movements of the eyeballs (nystagmus) occur. At a level higher than 30 mcg/mL, ataxia and slurred speech occur.

Test-Taking Strategy: Focus on the **subject,** a phenytoin level of 35 mcg/mL. Use knowledge regarding the therapeutic phenytoin level. From this point, you must know the symptoms that would be noted in the client when the phenytoin level is

Telegram & Insta: NCLEX_RN_Edu

35 mcg/mL. Remember that ataxia and slurred speech occur with levels higher than 30 mcg/mL.
Reference: Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. p. 932.

6. *Answer:* 1
Rationale: Mild intoxication with acetylsalicylic acid is called *salicylism* and is experienced commonly when the daily dosage is higher than 4 g. Tinnitus (ringing in the ears) is the most frequent effect noted with intoxication. Hyperventilation may occur, because salicylate stimulates the respiratory center. Fever may result, because salicylate interferes with the metabolic pathways coupling oxygen consumption and heat production. Options 2, 3, and 4 are not associated specifically with toxicity.
Test-Taking Strategy: Focus on the **subject,** acetylsalicylic acid intoxication. Options 2 and 3 relate to gastrointestinal symptoms, are **comparable or alike,** and are eliminated first. From the remaining options, you must know that tinnitus occurs.
Reference: Lilley, L., Rainforth Collins, S., & Snyder, J. (2020). *Pharmacology and the nursing process.* (9th ed.). St. Louis: Elsevier. pp. 682-683.

7. *Answer:* 3
Rationale: Carbamazepine, classified as an antiseizure medication, is used to treat nerve pain. Adverse effects of carbamazepine appear as blood dyscrasias, including aplastic anemia, agranulocytosis, thrombocytopenia, and leukopenia; cardiovascular disturbances, including thrombophlebitis and dysrhythmias; and dermatological effects. The low white blood cell count reflects agranulocytosis. The laboratory values in options 1, 2, and 4 are normal values.
Test-Taking Strategy: Focus on the **subject,** an adverse effect of carbamazepine. If you are familiar with normal laboratory values, you will note that the only option that indicates an abnormal value is the correct option.
References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. p. 247; Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. pp. 187-189.

8. *Answer:* 2
Rationale: While the client is taking morphine, the nurse would monitor vital signs and assess for hypotension and respiratory depression. The nurse would monitor respiratory status and initiate deep breathing and coughing exercises. In addition, the nurse monitors the effectiveness of the pain medication. The nurse also would increase fluid intake, palpate the bladder for urinary retention, auscultate bowel sounds, and monitor the pattern of daily bowel activity and stool consistency, because the medication causes constipation.
Test-Taking Strategy: Focus on the **subject**, a specific nursing consideration related to morphine. Eliminate options 1, 3, and 4 because they are **comparable or alike.** In addition, recall that opioid analgesics can cause constipation to assist in directing you to the correct option.
Reference: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. pp. 277, 298.

9. *Answer:* 2
Rationale: Typical antiseizure medication instructions include taking the prescribed daily dosage to keep the blood level of the medication constant and having a sample drawn for serum medication level determination before taking the morning dose. The client is taught not to stop the medication abruptly, to avoid alcohol, to check with a primary health care provider before taking over-the-counter medications, to avoid activities in which alertness and coordination are required until medication effects are known, to provide good oral hygiene, and to obtain regular dental care. The client needs to also wear a MedicAlert bracelet.
Test-Taking Strategy: Focus on the **subject,** an understanding of medication instructions for phenytoin. Using knowledge of general principles related to medication administration will assist you in eliminating options 1 and 3. From the remaining options, recall that medications generally are not taken just before determining therapeutic serum levels, because the results would be artificially high. This leaves oral hygiene as the correct option because of the risk of gingival hyperplasia.
References: Burchum, J., & Rosenthal, L. (2019). *Lehne's pharmacology for nursing care.* (10th ed.). St. Louis: Elsevier. p. 246; Kizior, R., & Hodgson, B. (2022). *Saunders nursing drug handbook 2022*. St. Louis: Elsevier. p. 932.

10. *Answer:* 4
Rationale: An edrophonium injection makes the client in cholinergic crisis temporarily worse. An improvement in the weakness indicates myasthenia crisis. Muscle spasms are not associated with this test.
Test-Taking Strategy: Focus on the **subject,** results of an edrophonium test. Recalling that a cholinergic crisis indicates an overdose of medication, it seems reasonable that a worsening of the condition will occur when additional medication is administered.
Reference: Huether, S., McCance, K. & Brashers, V. (2020). *Understanding pathophysiology*. (7th ed.). St. Louis: Elsevier. p. 406.

11. *Answer:* 4
Rationale: In adults, overdose of acetaminophen causes liver damage. The correct option is an indicator of liver function and is the only option that indicates an abnormal laboratory value. The normal direct bilirubin level is 0.1 to 0.3 mg/dL (1.7 to 5.1 mcmol/L). The normal sodium level is 135 to 145 mEq/L (135 to 145 mmol/L). The normal prothrombin time is 11 to 12.5 seconds (11 to 12.5 seconds). The normal platelet count is 150,000 to 400,000 mm^3 (150 to 400 × 10^9/L).
Test-Taking Strategy: Focus on the **subject,** acetaminophen toxicity. Knowledge that acetaminophen causes liver damage and knowledge of normal laboratory results will assist you in answering this question. The correct option is the only abnormal value. Also, of all the options, the bilirubin level is the laboratory value most directly related to liver function.
References: Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). UNIT XVI

Musculoskeletal Problems of the Adult Client

Pyramid to Success

The Pyramid to Success focuses on the emergency care for a client who sustains a fracture or other musculoskeletal injury, monitoring for complications, and carrying out interventions if complications occur. Nursing care related to casts and traction is emphasized. Skill related to instructing the client in the use of an assistive device such as a cane, walker, or crutches is discussed. Pyramid Points also include postoperative care following hip surgery or amputation and care of the client with rheumatoid arthritis or osteoporosis. The points related to the psychosocial effects as a result of the musculoskeletal disorder, such as unexpected body image changes, and the appropriate and available support services needed for the client are emphasized.

Client Needs: Learning Outcomes

Safe and Effective Care Environment

Communicating with the interprofessional health care team
Ensuring that informed consent is obtained for treatments and procedures
Handling hazardous and infectious materials safely
Maintaining asepsis related to wounds
Maintaining confidentiality
Maintaining standard and other precautions
Preventing accidents and injuries
Prioritizing hypotheses based on client needs
Providing physical therapy and occupational therapy referrals
Upholding client rights

Health Promotion and Maintenance

Generating solutions regarding home care for a client with a musculoskeletal problem
Performing physical assessment related to the musculoskeletal system
Preventing diseases that occur as a result of the aging process
Promoting health related to diet and activity
Providing home care instructions regarding care related to a musculoskeletal disorder
Recognizing cues that indicate risk factors for a musculoskeletal disorder
Reinforcing the importance of prescribed therapy

Psychosocial Integrity

Assessing available support systems and use of community resources
Assessing the client's ability to cope with mobility limitations and restrictions, feelings of isolation, and loss of independence
Considering cultural, religious, and spiritual influences
Discussing situational role changes as a result of the musculoskeletal disorder
Discussing unexpected body image changes as a result of injury or disease
Identifying sensory and perceptual alterations
Mobilizing coping mechanisms

Physiological Integrity

Analyzing cues related to complications of procedures, injuries, or a fracture
Evaluating for expected and unexpected responses to treatment measures
Initiating teaching related to pharmacological therapy
Providing care following diagnostic testing and procedures and surgical interventions
Providing care related to casts and traction
Promoting normal elimination patterns
Promoting self-care measures
Providing measures to promote comfort
Taking action in emergency care for a fracture or other injury
Taking action in emergency care if complications following injuries or surgical interventions arise
Teaching about the use of assistive devices for mobility such as canes, walkers, and crutches

CHAPTER 61

Musculoskeletal Problems

Contributor: Sarah R. Jean Baptiste, MS, PA-C

PRIORITY CONCEPTS **Functional Ability; Mobility**

I. Anatomy and Physiology

A. Skeleton
- **1.** Axial portion
  - **a.** Cranium
  - **b.** Vertebrae
  - **c.** Ribs
- **2.** Appendicular portion
  - **a.** Limbs
  - **b.** Shoulders (scapulae, clavicles)
  - **c.** Hips (pelvis)

B. Types of bones: Long, short, flat, irregular
- **1.** Spongy bone
  - **a.** Spongy bone is located in the ends of long bones and the center of flat and irregular bones.
  - **b.** Spongy bone can withstand forces applied in many directions.
- **2.** Dense (compact) bone
  - **a.** Dense bone covers spongy bone.
  - **b.** Forms a cylinder around a central marrow cavity
  - **c.** Better able to withstand longitudinal forces than horizontal forces
- **3.** Characteristics of bones
  - **a.** Support and protect structures of the body
  - **b.** Provide attachments for muscles, tendons, and ligaments
  - **c.** Contain tissue in the central cavities, which aids in the formation of blood cells
  - **d.** Assist in regulating calcium and phosphate concentrations
- **4.** Bone growth
  - **a.** The length of bone growth results from ossification of the epiphyseal cartilage at the ends of bones; bone growth stops between the ages of 18 and 25 years.
  - **b.** The width of bone growth results from the activity of osteoblasts; it occurs throughout life but slows down with aging.

As aging occurs, bone resorption accelerates, decreasing bone mass and predisposing the client to injury.

C. Types of joints (Table 61.1)
- **1.** Characteristics of joints
  - **a.** Allow movement between bones
  - **b.** Formed where two bones join
  - **c.** Surfaces are covered with cartilage.
  - **d.** Enclosed in a capsule (synovial joints)
  - **e.** Contain a cavity filled with synovial fluid (synovial joints)
  - **f.** Ligaments hold the bone and joint in the correct position.
  - **g.** Articulation is the meeting point of two or more bones.
- **2.** Synovial fluid
  - **a.** Found in the synovial joint capsule
  - **b.** Formed by the synovial membrane, which lines the joint capsule
  - **c.** Lubricates the cartilage
  - **d.** Provides a cushion against shocks

D. Muscles
- **1.** Characteristics of muscles
  - **a.** Made up of bundles of muscle fibers
  - **b.** Provide the force to move bones
  - **c.** Assist in maintaining posture
  - **d.** Assist with heat production
- **2.** Process of contraction and relaxation
  - **a.** Muscle contraction and relaxation require large amounts of adenosine triphosphate.
  - **b.** Contraction also requires calcium, which functions as a catalyst.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

c. Acetylcholine released by the motor end plate of the motor neuron initiates an action potential.
d. Acetylcholine is then destroyed by acetylcholinesterase.
e. Calcium is required for muscle fiber contraction and acts as a catalyst for the enzyme needed for the sliding-together action of actin and myosin.
f. Following contraction, adenosine triphosphate transports calcium out to allow actin and myosin to separate and allow the muscle to relax.

3. Skeletal muscles
a. Skeletal muscles are attached to two bones by cartilaginous tendons called *enthuses* (the connective tissue between tendon or ligament and bone).
b. The point of origin is the point of attachment that does not move.
c. The point of insertion is the point of attachment that moves when the muscle contracts.
d. Skeletal muscles act in groups.
e. Prime movers contract to produce movement.
f. Antagonists relax.
g. Synergists contract to stabilize body movement.
h. Nerves activate and control the muscles.

TABLE 61.1 Types of Joints

Type	Description
Amphiarthrosis	Cartilaginous joint Slightly movable
Diarthrosis	Synovial joint Ball-and-socket joint Permit free movement
Synarthrosis	Fibrous or fixed joint No movement associated with these joints

Huether, S., McCance, K., & Brashers, V. (2020). *Understanding pathophysiology*. (7th ed.). St. Louis: Elsevier. p. 940.

E. Bone healing
1. Description: Bone union or healing is the process that occurs after the integrity of a bone is interrupted.
2. Stages (Fig. 61.1)

II. Risk Factors Associated with Musculoskeletal Problems: See Box 61.1

III. Diagnostic Tests

A. Radiography and magnetic resonance imaging (MRI) (refer to Chapter 59 for information on MRI)
1. Description: Radiography and MRI are commonly used procedures to diagnose problems of the musculoskeletal system.
2. Interventions
a. Handle injured areas carefully and support extremities above and below the joint.
b. Administer analgesics as prescribed before the procedure, particularly if the client is in pain.
c. Remove any radiopaque and metallic objects, such as jewelry.
d. Ask the client about being pregnant; certain precautions may be necessary.
e. Shielding of the client's testes or ovaries or other body areas may be necessary depending

BOX 61.1 Risk Factors Associated with Musculoskeletal Problems

- Autoimmune disorders
- Calcium deficiency
- Falls
- Hyperuricemia
- Infection
- Medications
- Metabolic disorders
- Neoplastic disorders
- Obesity
- Postmenopausal states
- Trauma and injury

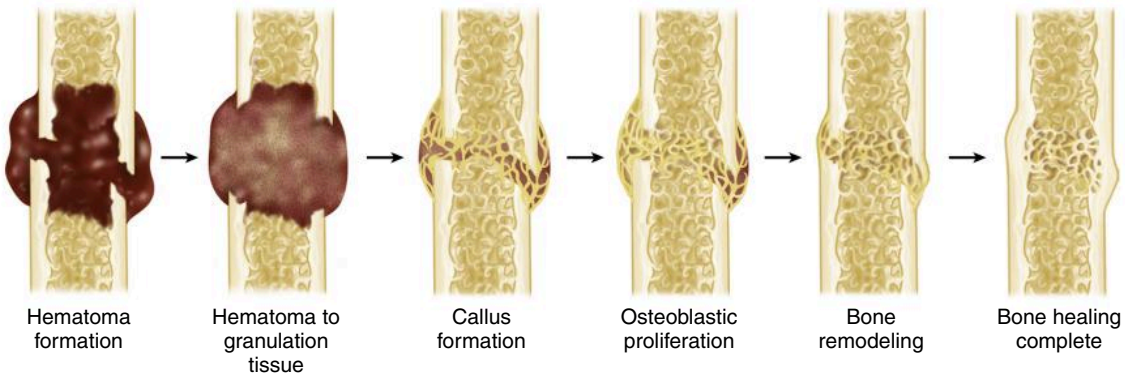

FIG. 61.1 The stages of bone healing.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

on agency procedures, and if there is a prescription to do so.
- **f.** The client must lie still during a procedure.
- **g.** If the client is getting an MRI, ensure that the client has no metal implants with magnetic properties (e.g., a pacemaker, stents) and no history of metallic foreign bodies.
- **h.** Inform the client that exposure to radiation from radiography is minimal and not dangerous.
- **i.** The health care provider wears a lead apron if staying in the room with the client having radiography.
- **j.** Complete the screening process per agency policy.

B. Arthrocentesis
1. Description: Arthrocentesis is used to diagnose joint inflammation and infection.
   - **a.** Arthrocentesis involves aspirating synovial fluid, blood, or pus via a needle inserted into a joint cavity.
   - **b.** Medication, such as corticosteroids, may be instilled into the joint if necessary to alleviate inflammation.
2. Interventions
   - **a.** Ensure that informed consent has been obtained.
   - **b.** Apply an elastic compression bandage postprocedure as prescribed.
   - **c.** Use ice to decrease pain and swelling.
   - **d.** Pain may worsen after aspirating fluid from the joint; analgesics may be prescribed.
   - **e.** Pain can continue for up to 2 days after administration of corticosteroids into a joint.
   - **f.** Clients with diabetes mellitus should be advised that corticosteroid injections may cause an increase in blood glucose levels for a day or more.
   - **g.** Instruct the client to rest the joint for 8 to 24 hours postprocedure.
   - **h.** Instruct the client to notify the primary health care provider (PHCP) if a fever or swelling of the joint occurs.

C. Arthroscopy
1. Description: Used to diagnose and treat acute and chronic problems of the joint
   - **a.** Arthroscopy provides an endoscopic examination of various joints.
   - **b.** Cartilage abnormalities can be assessed, loose bodies removed, torn ligaments and tendons repaired or reconstructed, and the cartilage trimmed or repaired.
   - **c.** A biopsy may be performed during the procedure.
2. Interventions
   - **a.** Instruct the client to fast for 8 to 12 hours before the procedure.
   - **b.** Ensure that informed consent was obtained.
   - **c.** Administer pain medication as prescribed postprocedure.
   - **d.** Assess the neurovascular status of the affected extremity.
   - **e.** An elastic compression bandage should be worn postprocedure for 2 to 4 days as prescribed. If client complains that it feels too restrictive, readjust the bandage.
   - **f.** Instruct the client that walking with weight bearing usually is permitted after sensation returns but to limit activity as prescribed following the procedure.
   - **g.** Instruct the client to elevate the extremity as often as possible for 24 hours following the procedure and to place ice on the site to minimize swelling for 12 to 24 hours postprocedure.
   - **h.** Advise the client to notify the PHCP if fever or increased knee pain occurs, if there is increasing redness around the incision(s), persistent drainage from the incisions for more than 3 days, or if edema continues for more than 3 days postprocedure.

D. Bone mineral density measurements
1. Dual-energy x-ray absorptiometry
   - **a.** Dual-energy x-ray absorptiometry measures the bone mass of the spine, wrist and hip bones, and total body.
   - **b.** Radiation exposure is minimal.
   - **c.** It is used to diagnose metabolic bone disease and to monitor changes in bone density with treatment.
   - **d.** Inform the client that the procedure is painless.
   - **e.** All metallic objects are removed before the test.
2. Quantitative ultrasound
   - **a.** Quantitative ultrasound evaluates strength, density, and elasticity of various bones, using ultrasound rather than radiation.
   - **b.** Inform the client that the procedure is painless.

E. Bone scan
1. Description: A bone scan is used to identify, evaluate, and stage bone cancer before and after treatment; it is also used to detect fractures or loosening of total joint replacements.
   - **a.** Radioisotope is injected intravenously and will collect in areas that indicate abnormal bone metabolism and some fractures, if they exist.
   - **b.** The isotope is excreted in the urine and feces within 48 hours and is not harmful to others.
2. Interventions
   - **a.** Food and fluids may be withheld before the procedure.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

b. Ensure that informed consent has been obtained.
c. Remove all jewelry and metal objects.
d. Following the injection of the radioisotope, the client must drink 32 oz of water (if not contraindicated) to promote renal filtering of the excess isotope.
e. From 1 to 3 hours after the injection, have the client void to clear excess isotope from the bladder before the scanning procedure is completed.
f. Inform the client of the need to lie supine during the procedure and that the procedure is not painful.
g. Monitor the injection site for redness and swelling.
h. Encourage oral fluid intake following the procedure.

⚠ No special precautions are required after a bone scan, because only a minimal amount of radioactivity exists in the radioisotope used for the procedure.

F. Bone or muscle biopsy
1. Description: Biopsy may be done during surgery or through aspiration or punch or needle biopsy.
2. Interventions
a. Ensure that informed consent was obtained.
b. Monitor for bleeding, swelling, hematoma, or severe pain.
c. Elevate the site for 24 hours following the procedure to reduce edema.
d. Apply ice packs as prescribed following the procedure to prevent the development of a hematoma and to decrease site discomfort.
e. Monitor for signs of infection following the procedure.
f. Inform the client that mild to moderate discomfort is normal following the procedure.

G. Electromyography (EMG)
1. Description: EMG is used to evaluate muscle health and the nerves that control them. It is often a valuable assessment tool for determining weakness.
a. Electromyography measures electrical potential associated with skeletal muscle contractions.
b. Needles are inserted into the muscle, and recordings of muscular electrical activity are traced on recording paper through an oscilloscope.
2. Interventions
a. Ensure that informed consent was obtained.
b. Instruct the client that the needle insertion is uncomfortable.
c. Instruct the client not to take any stimulants or sedatives for 24 hours before the procedure.
d. Inform the client that slight bruising may occur at the needle insertion sites.
e. Mild analgesics can be used for the pain.

IV. Injuries

A. Strains
1. Strains are an excessive stretching of a muscle or tendon.
2. Management involves cold and heat applications, exercise with activity limitations, antiinflammatory medications, and muscle relaxants.
3. Surgical repair may be required for a severe strain (ruptured muscle or tendon).

B. Sprains
1. Sprains are an excessive stretching or a tear of a ligament, usually caused by a twisting motion, such as in a fall or stepping onto an uneven surface.
2. Sprains are characterized by pain and swelling.
3. Management involves rest, ice, a compression bandage, and elevation (RICE) to reduce swelling, as well as joint support. RICE is considered a first-aid treatment, rather than a cure for soft tissue injuries.
4. Casting may be required for moderate sprains to allow the tear to heal.
5. Surgery may be necessary for severe ligament damage.

C. Rotator cuff injuries
1. The musculotendinous or rotator cuff of the shoulder can sustain a tear, usually as a result of trauma or chronic wear and tear/overuse.
2. Injury is characterized by shoulder pain and the inability to maintain abduction of the arm at the shoulder (drop arm test).
3. Management involves nonsteroidal antiinflammatory drugs (NSAIDs), physical therapy, sling support, and ice–heat applications.
4. Surgery may be required if medical management is unsuccessful or a complete tear is present.

V. Fractures

A. Description: A break in the continuity of the bone caused by trauma, twisting as a result of muscle spasm or indirect loss of leverage, or bone decalcification and disease that result in osteopenia
B. Types of fractures (Fig. 61.2 and Box 61.2)
C. Assessment of a fracture of an extremity
1. Pain or tenderness over the involved area
2. Decrease or loss of muscular strength or function
3. Obvious deformity of the affected area
4. Crepitation, erythema, edema, or bruising
5. Muscle spasm and neurovascular impairment
D. Initial care of a fracture of an extremity
1. Immobilize the affected extremity with a cast or splint.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

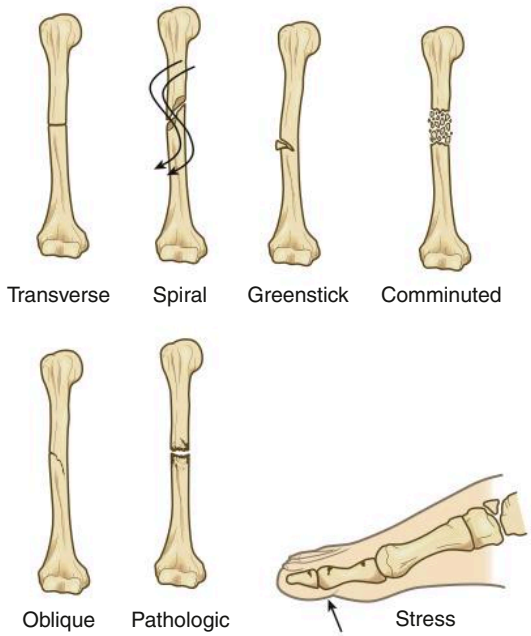

FIG. 61.2 Some types of fractures. Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier.

BOX 61.2 Types of Fractures

Closed or Simple: Skin over the fractured area remains intact.
Compound or Open: The bone is exposed to air through a break in the skin, and soft tissue injury and infection are common.
Comminuted: The bone is splintered or crushed, creating numerous fragments.
Complete: The bone is separated completely by a break into two parts.
Compression: A fractured bone is compressed by other bone.
Depressed: Bone fragments are driven inward.
Greenstick: One side of the bone is broken and the other is bent; these fractures occur most commonly in children.
Impacted: A part of the fractured bone is driven into another bone.
Incomplete: Fracture line does not extend through the full transverse width of the bone.
Oblique: The fracture line runs at an angle across the axis of the bone.
Pathological: The fracture results from weakening of the bone structure by pathological processes such as neoplasia; also called *spontaneous fracture.*
Spiral: The break partially encircles bone.
Stress: Occurs in normal or abnormal bone exposed to repeated stress.
Transverse: The bone is fractured straight across.

2. Assess the neurovascular status of the extremity.
3. Interventions for a fracture: **Reduction, fixation, traction, cast**

⚠ If a compound (open) fracture exists, splint the extremity and cover the wound with a sterile dressing.

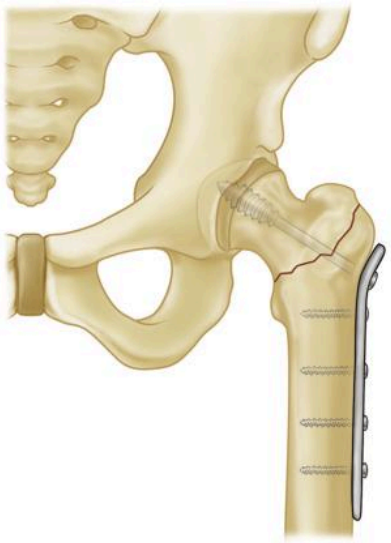

FIG. 61.3 A compression hip screw used for open reduction with internal fixation.

E. Reduction restores the bone to proper alignment.
1. Closed reduction is a nonsurgical intervention performed by manual manipulation.
   a. Closed reduction may be performed under local or general anesthesia.
   b. A cast may be applied following reduction.
2. Open reduction involves a surgical intervention; the fracture may be treated with **internal fixation** devices.

F. Fixation
1. Internal fixation follows an open reduction (Fig. 61.3).
   a. Internal fixation involves the application of screws, plates, pins, wires, or intramedullary rods to hold the fragments in alignment.
   b. Internal fixation may involve the removal of damaged bone and replacement with a prosthesis.
   c. Internal fixation provides immediate bone stabilization.
2. **External fixation** is the use of an external frame to stabilize a fracture by attaching skeletal pins through bone fragments to a rigid external support (Fig. 61.4).
   a. External fixation provides more freedom of movement than with traction.
   b. Monitor pin stability and provide pin care to decrease infection risks.
   c. Risk of infection exists with both fixation methods.
   d. External fixation is commonly used when massive tissue trauma is present.

G. Traction (Fig. 61.5)
1. Description
   a. Traction is the exertion of a pulling force applied in two directions to reduce and immobilize a fracture.

Telegram & Insta: NCLEX_RN_Edu

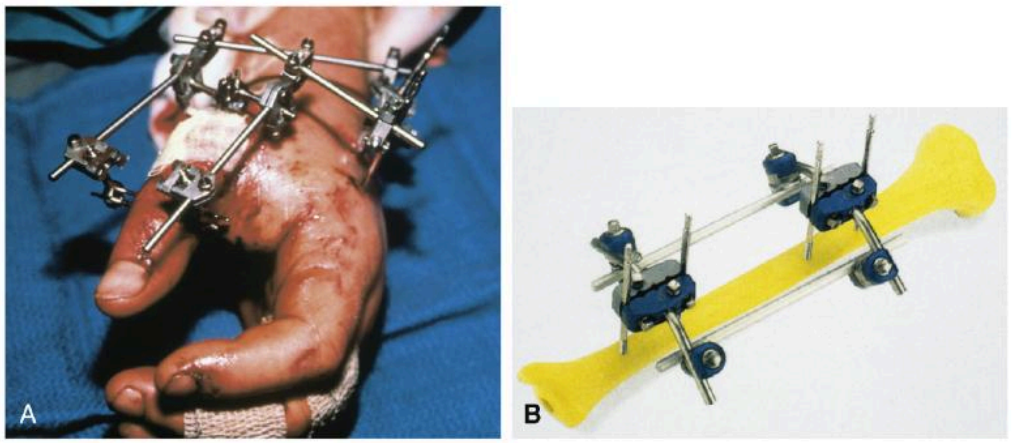

FIG. 61.4 External fixators. **A,** Mini-Hoffman system in use on hand. **B,** Hoffman II on the tibia (standard system). Lewis, S., Harding, M., Kwong, J., Roberts, D., Hagler, D., & Reinisch, C. (2020). *Medical-surgical nursing: Assessment and management of clinical problems.* (11th ed.). St. Louis: Elsevier. p. 1455.

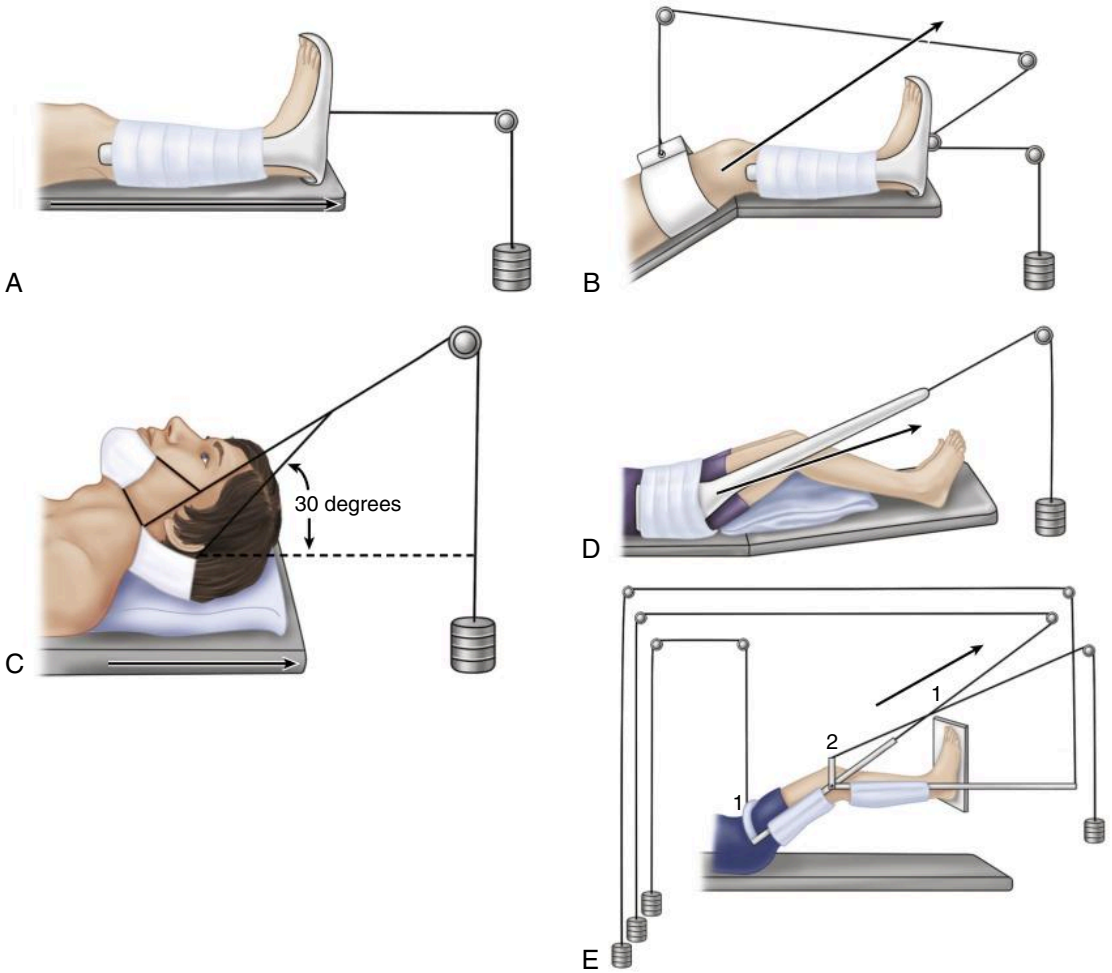

FIG. 61.5 Types of traction. **A,** Buck's traction. **B,** Russell's traction. **C,** Head halter traction. **D,** Pelvic traction. **E,** Balanced suspension traction.

b. It provides proper bone alignment and reduces muscle spasms.

2. Interventions

a. Maintain proper body alignment.

b. Ensure that the weights hang freely and do not touch the floor.

c. Do not remove or lift the weights without a PHCP's prescription.

d. Ensure that pulleys are not obstructed and that ropes in the pulleys move freely.

e. Place knots in the ropes to prevent slipping.

f. Check the ropes for fraying.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

H. Skeletal traction
- **1.** Description
  - **a.** Traction is applied mechanically to the bone with pins, wires, or tongs.
  - **b.** Typical weight for skeletal traction is 25 to 40 lb (11 to 18 kg).
- **2.** Interventions
  - **a.** Monitor color, motion, and sensation of the affected extremity.
  - **b.** Monitor the insertion sites for redness, swelling, drainage, or increased pain.
  - **c.** Provide insertion site care as prescribed.
- **3.** Cervical tongs and a halo fixation device: See Chapter 59 regarding care of the client with these types of devices.

I. Skin traction
- **1.** Description: Skin traction is applied by using elastic bandages or adhesive, foam boot, or sling. Be cautious to avoid excessive pressure on the skin that could result in a pressure injury or skin breakdown. Wrapping too tight could also increase the risk of compartment syndrome.
- **2.** Cervical skin traction relieves muscle spasms and compression in the upper extremities and neck (see Fig. 61.5).
  - **a.** Cervical skin traction uses a head halter and chin pad to attach the traction.
  - **b.** Use powder to protect the ears from friction rub.
  - **c.** Position the client with the head of the bed elevated 30 to 40 degrees, and attach the weights to a pulley system over the head of the bed.
- **3.** Buck's (extension) skin traction is used to alleviate muscle spasms and immobilize a lower limb by maintaining a straight pull on the limb with the use of weights (see Fig. 61.5).
  - **a.** A boot appliance is applied to attach to the traction.
  - **b.** The weights are attached to a pulley; allow the weights to hang freely over the edge of the bed.
  - **c.** Not more than 8 to 10 lb (3.5 to 4.5 kg) of weight should be applied as prescribed.
  - **d.** Elevate the foot of the bed to provide the traction.
- **4.** Russell's skin (sling) traction: See Fig. 61.5 and Chapter 40 regarding this type of traction.
- **5.** Pelvic skin traction is used to relieve low back, hip, or leg pain or to reduce muscle spasm (see Fig. 61.5).
  - **a.** Apply the traction belt snugly over the pelvis and iliac crest and attach to the weights.
  - **b.** Use measures as prescribed to prevent the client from slipping down in bed.

J. Balanced suspension traction (see Fig. 61.5)
- **1.** Description
  - **a.** Balanced suspension traction is used with skin or skeletal traction.
  - **b.** Used to approximate fractures of the femur, tibia, or fibula
  - **c.** Balanced suspension traction is produced by a counterforce other than the client.
- **2.** Interventions
  - **a.** Position the client in a low-Fowler's position on either the side or the back.
  - **b.** Maintain a 20-degree angle from the thigh to the bed.
  - **c.** Protect the skin from breakdown.
  - **d.** Provide pin care if pins are used with skeletal traction.
  - **e.** Clean the pin sites with sterile normal saline and hydrogen peroxide or povidone-iodine as prescribed or per agency policy.

K. Casts
- **1.** Description: Plaster, fiberglass, or air casts are used to immobilize bones and joints into correct alignment after a fracture or injury.
- **2.** Interventions
  - **a.** Keep the cast and extremity elevated.
  - **b.** Allow a wet plaster cast 24 to 72 hours to dry (synthetic casts dry in 20 minutes).
  - **c.** Handle a wet plaster cast with the palms of the hands (not fingertips) until dry.
  - **d.** Turn the extremity every 1 to 2 hours, unless contraindicated, to allow air circulation and promote drying of the cast.
  - **e.** A hair dryer can be used on a cool setting to dry a plaster cast (heat cannot be used on a plaster cast, because the cast heats up and burns the skin).
  - **f.** Monitor closely for circulatory impairment; prepare for bivalving or cutting the cast if circulatory impairment occurs.
  - **g.** Petal the cast or apply moleskin to the edges to protect the client's skin; maintain smooth edges around the cast to prevent crumbling of the cast material.
  - **h.** Monitor for signs of infection such as increased temperature, hot spots on the cast, foul odor, or changes in pain.
  - **i.** If an open draining area exists on the affected extremity, the PHCP will make a cutout portion of the cast known as a *window*, for assessment and wound care purposes.
  - **j.** Instruct the client not to stick objects inside the cast.
  - **k.** Teach the client to keep the cast clean and dry.
  - **l.** Instruct the client in isometric exercises to prevent muscle atrophy.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 61.3 Complications of Fractures

- Avascular necrosis
- Compartment syndrome
- Fat embolism
- Infection and osteomyelitis

Monitor a casted extremity for circulatory impairment such as pain, swelling, discoloration, tingling, numbness, coolness, or diminished pulse. Notify the PHCP immediately if circulatory compromise occurs.

VI. Complications of Fractures (Box 61.3)

A. Fat embolism

1. Description: An embolism is caused by the movement of foreign particles (blood clot, fat, or air) into the pulmonary circulation.
2. Assessment (see Clinical Judgment: Analyze Cues Box)
   a. Restlessness and apprehension
   b. Sudden onset of dyspnea and chest pain
   c. Cough, hemoptysis, hypoxemia, or crackles
3. Interventions
   a. Notify the primary PHCP.
   b. Administer oxygen.
   c. Administer intravenous (IV) fluids as prescribed; intravenous (IV) anticoagulant therapy may be prescribed.
   d. Monitor vital signs and respiratory status.
   e. Follow up on results of diagnostic tests such as chest x-ray or computed tomography (CT) scan.
   f. Prepare for intubation and mechanical ventilation if necessary as indicated by arterial blood gas values.
   g. Document the event, actions taken, and the client's response.

CLINICAL JUDGMENT: ANALYZE CUES

The nurse is caring for a hospitalized client who sustained a femur fracture in a motor vehicle crash and is placed in balanced suspension traction to approximate the fracture. The client calls the nurse and complains of sudden chest pain and difficulty breathing. The client is restless and confused, is coughing, and the nurse hears bilateral crackles in the lungs. The nurse analyzes these cues and suspects a fat embolism.

B. Acute Compartment Syndrome

1. Description
   a. Tough fascia surrounds muscle groups, forming compartments from which arteries, veins, and nerves enter and exit at opposite ends.
   b. Compartment syndrome is a painful condition that occurs when pressure increases within one or more compartments, leading to decreased blood flow, tissue ischemia, and neurovascular impairment. It is a medical emergency that can result in severe injury if not addressed quickly.
   c. Neurovascular damage may be irreversible if not treated within 4 to 6 hours after the onset of compartment syndrome.
   d. Occurs most commonly in the lower leg
2. Assessment
   a. Unrelieved or increased pain in the limb
   b. Tissue that is distal to the involved area becomes pale, dusky, or edematous.
   c. Pain with passive movement
   d. Loss of sensation (paresthesia)
   e. Pulselessness (a late sign)
3. Interventions
   a. Notify the PHCP immediately and prepare to assist the PHCP.
   b. Loosen tight dressings or bivalve restrictive cast as prescribed.
   c. If severe, assist the PHCP with fasciotomy to relieve pressure and restore tissue perfusion.

C. Infection and osteomyelitis

1. Description: Infection and osteomyelitis (inflammatory response in bone tissue) can be caused by the introduction of organisms into bones, leading to localized bone infection.
2. Assessment
   a. Tachycardia and fever (usually above 101° F [38.3° C])
   b. Erythema and pain in the area surrounding the infection
   c. Leukocytosis and elevated erythrocyte sedimentation rate (ESR)
   d. Confirmed by radiographic assessment, such as plain radiographs, MRI, or bone scan
3. Interventions
   a. Notify the PHCP.
   b. Prepare to initiate aggressive, long-term IV antibiotic therapy. A central venous access line will likely be required.
   c. Surgery is performed for resistant osteomyelitis with sequestrectomy and/or bone grafts.
   d. For unrelenting infection and osteomyelitis, hyperbaric oxygen therapy is used (if available) to promote healing.

D. Avascular necrosis

1. Description: Avascular necrosis occurs when a fracture interrupts the blood supply to a section of bone, leading to bone death.
2. Assessment
   a. Pain
   b. Decreased sensation
   c. Confirmed by radiographic assessment, such as plain radiographs, MRI, or bone scan

TABLE 61.2 Crutch Gaits

Type of Gait	Use	Procedure
Two-point gait	Used with partial weight-bearing limitations and with bilateral lower extremity prostheses	The crutch on the affected side and the unaffected foot are advanced at the same time.
Three-point gait	Used for partial weight bearing or no weight bearing on the affected leg; requires that the client have strength and balance	Both crutches and the foot of the affected extremity are advanced together, followed by the foot of the unaffected extremity.
Four-point gait	Used if weight bearing is allowed and one foot can be placed in front of the other	The right crutch is advanced, then the left foot, then the left crutch, and then the right foot.
Swing-to gait	Used when there is adequate muscle power and balance in the arms and legs	Both crutches are advanced together, then both legs are lifted and placed down on a spot behind the crutches. The feet and crutches form a tripod.
Swing-through gait	Used when there is adequate muscle power and balance in the arms and legs	Both crutches are advanced together; then both legs are lifted through and beyond the crutches and placed down again at a point in front of the crutches.

Adapted from Potter, P., Perry, A. G., Stockert, P. A., & Hall, A. M. (2021). *Fundamentals of nursing.* (10th ed.). St. Louis: Elsevier. pp. 798-799.

3. Interventions
   a. Notify the PHCP if pain or numbness occurs.
   b. Where indicated, prepare for surgical intervention. Necrotic tissue can serve as a focus for infection or can lead to secondary arthritis if involving a joint.

VII. Crutch Walking

A. Description
   1. An accurate measurement of the client for crutches is important, because an incorrect measurement could damage the brachial plexus.
   2. The distance between the axillae and the arm pieces on the crutches should be 2 to 3 finger widths in the axilla space.
   3. The elbows should be slightly flexed, 20 to 30 degrees, when the client is walking.
   4. When ambulating with the client, stand on the affected side.
   5. Instruct the client never to rest the axillae on the axillary bars.
   6. Instruct the client to look up and outward when ambulating and to place the crutches 6 to 10 inches (25.5 cm) diagonally in front of the foot.
   7. Instruct the client to stop ambulation if numbness or tingling in the hands or arms occurs.

B. Crutch gaits (Table 61.2)

C. Assisting the client with crutches to sit and stand
   1. Place the unaffected leg against the front of the chair.
   2. Move the crutches to the affected side, and grasp the arm of the chair with the hand on the unaffected side.
   3. Flex the knee of the unaffected leg to lower self into the chair while placing the affected leg straight out in front.
   4. Reverse the steps to move from a sitting to standing position.

D. Going up and down stairs
   1. Up the stairs
      a. The client moves the unaffected leg up first.
      b. The client moves the affected leg and the crutches up.
   2. Down the stairs
      a. The client moves the crutches and the affected leg down.
      b. The client moves the unaffected leg down.

VIII. Canes and Walkers

A. Description: Canes and walkers are made of a lightweight material with a rubber tip at the bottom.

B. Interventions
   1. Stand at the affected side of the client when ambulating; use of a gait or transfer belt may be necessary.
   2. The handle should be at the level of the client's greater trochanter.
   3. The client's elbow should be flexed at a 15- to 30-degree angle.
   4. Instruct the client to hold the cane 4 to 6 inches (10 to 15 cm) to the side of the foot.
   5. Instruct the client to hold the cane in the hand on the unaffected side so that the cane and weaker leg can work together with each step.
   6. Instruct the client to move the cane at the same time as the affected leg.
   7. Instruct the client to inspect the rubber tips regularly for worn places.

C. Hemicanes or quadripod canes
   1. Hemicanes or quadripod canes are used for clients who have the use of only one upper extremity.
   2. Hemicanes provide more security than a quadripod cane; however, both types provide more security than a single-tipped cane.
   3. Position the cane at the client's unaffected side, with the straight, nonangled side adjacent to the body.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

4. Position the cane 6 inches (15 cm) from the unaffected client's side, with the hand grip level with the greater trochanter.

D. Walker

1. Stand adjacent to the client on the affected side.
2. Instruct the client to put all four points of the walker flat on the floor before putting weight on the hand pieces.
3. Instruct the client to move the walker forward, followed by the affected or weaker foot and then the unaffected foot.

Safety is the priority concern when the client uses an assistive device such as a cane, walker, or crutches. Be sure that the client demonstrates correct use of the device.

IX. Fractured Hip

A. Types

1. Intracapsular (femoral head is broken within the joint capsule)
   - **a.** Femoral head and neck receive decreased blood supply and heal slowly.
   - **b.** Skin traction is applied preoperatively to reduce the fracture and decrease muscle spasms.
   - **c.** Treatment includes hip replacement or open reduction internal fixation (ORIF).
   - **d.** To prevent hip dislocation postoperatively, avoid hip flexion beyond 90 degrees, avoid crossing legs or pointing toes inward (internal rotation of the hip), and check the surgeon's prescriptions regarding positioning.
2. Extracapsular (fracture is outside the joint capsule)
   - **a.** Fracture can occur at the greater trochanter or can be an intertrochanteric fracture.
   - **b.** Preoperative treatment includes balanced suspension or skin traction to relieve muscle spasms and reduce pain.
   - **c.** Surgical treatment includes ORIF with nail plate or intramedullary fixation.

B. Postoperative interventions

1. Monitor for signs of delirium, and institute safety measures.
2. Maintain leg and hip in proper alignment, and prevent internal or external rotation; avoid extreme hip flexion.
3. Follow the PHCP's prescriptions regarding turning and repositioning; usually, turning to the unaffected side is allowed; protective devices may be prescribed.
4. Elevate the head of the bed 30 to 45 degrees for meals only.
5. Assist the client to ambulate as prescribed by the PHCP.
6. Avoid weight bearing on the affected leg as prescribed; instruct the client in the use of a walker to avoid weight bearing.
7. Weight bearing is often restricted after ORIF and may not be restricted after total hip arthroplasty (THA); always refer to the PHCP's prescriptions.
8. Keep the operative leg extended, supported, and elevated (preventing hip flexion) when getting the client out of bed.
9. Avoid hip flexion greater than 90 degrees, and avoid low chairs when out of bed.
10. Monitor for wound infection or hemorrhage.
11. Administer antibiotics if prescribed within a specified time frame (antibiotics also may be prescribed in the preoperative period).
12. Neurovascular assessment of affected extremity: Check color, pulses, capillary refill, movement, and sensation.
13. Maintain the compression of the drain, if present, to facilitate wound drainage.
14. Monitor and record drainage amount, which decreases consistently.
15. As prescribed, carry out postoperative blood salvage to collect, filter, and reinfuse salvaged blood into the client.
16. Use antiembolism stockings or sequential compression stockings as prescribed; encourage the client to flex and extend the feet to reduce the risk of deep vein thrombosis (DVT).
17. Instruct the client to avoid crossing the legs and activities that require bending over.
18. Physical therapy will be instituted postoperatively with progressive ambulation as prescribed by the PHCP.

X. Total Knee Replacement

A. Description: Total knee replacement is the implantation of a device to substitute for the femoral condyles and tibial joint surfaces.

B. Postoperative interventions

1. Monitor surgical incision for drainage and infection.
2. If prescribed, continuous passive motion (CPM) is started soon after the client is admitted to the postoperative unit.
3. Administer analgesics before CPM to decrease pain.
4. Prepare the client for out-of-bed activities as prescribed; have the client avoid leg dangling.
5. Weight bearing with an assistive device is prescribed as tolerated.
6. Postoperative blood salvage may be prescribed to collect, filter, and reinfuse salvaged blood into the client.
7. Tranexamic acid is often given during the procedure as it has been shown to reduce blood loss and results in fewer postoperative blood transfusions.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. Administer antibiotics if prescribed within a specified time frame (antibiotics also may be prescribed in the preoperative period).

XI. Joint Dislocation and Subluxation

A. Dislocation: Injury of the ligaments surrounding a joint, which leads to displacement or separating of the articular surfaces of the joint

B. Subluxation: Incomplete displacement of joint surfaces when forces disrupt the soft tissue that surrounds the joints

C. Assessment

1. Asymmetry of the contour of affected body parts
2. Pain, tenderness, dysfunction, and swelling
3. Complications include neurovascular compromise, avascular necrosis, and open joint injuries.
4. X-rays are taken to determine joint shifting.

D. Interventions

1. Focus of treatment includes pain relief, joint support, and joint protection.
2. Immediate treatment is done to reduce the dislocation and realign the dislocated joint.
3. Open or closed reduction is done, followed with a postprocedural joint immobilization device.
4. Intravenous conscious sedation, local, or general anesthesia is used during joint manipulation.
5. Initial activity restriction is followed by gentle range-of-motion activities and a gradual return of activities to normal levels while supporting the affected joint.
6. A weakened joint is prone to recurrent dislocation and may require extended activity restriction.

XII. Herniation: Intervertebral Disc

A. Description: The nucleus of the disc protrudes into the annulus, causing nerve compression.

B. Cervical disc herniation occurs at the C5 to C6 and C6 to C7 interspaces.

1. Cervical disc herniation causes pain radiation to shoulders, arms, hands, scapulae, and pectoral muscles.
2. Motor and sensory deficits can include paresthesia, numbness, and weakness of the upper extremities.
3. Interventions
   - **a.** Conservative management is used unless the client develops signs of neurological deterioration.
   - **b.** Bed rest is prescribed to decrease pressure, inflammation, and pain.
   - **c.** Immobilize the cervical area with a cervical collar or brace.
   - **d.** Apply heat to reduce muscle spasms and apply ice to reduce inflammation and swelling.
   - **e.** Maintain head and spine alignment.
   - **f.** Instruct the client in the use of analgesics, sedatives, antiinflammatory agents, and corticosteroids as prescribed.
   - **g.** Prepare the client for a corticosteroid injection into the epidural space if prescribed.
   - **h.** Assist and instruct the client in the use of a cervical collar or cervical traction as prescribed.
4. Cervical collar is used for cervical disc herniation.
   - **a.** A cervical collar limits neck movement and holds the head in a neutral or slightly flexed position.
   - **b.** The cervical collar may be worn intermittently or 24 hours daily.
   - **c.** Inspect the skin under the collar for irritation.
   - **d.** When prescribed and after pain decreases, exercises are done to strengthen the muscles.
5. Client education related to cervical disc conditions
   - **a.** Avoid flexing, extending, and rotating the neck.
   - **b.** Avoid the prone position and maintain the neck, spine, and hips in a neutral position while sleeping.
   - **c.** Minimize long periods of sitting.
   - **d.** Instruct the client regarding medications such as analgesics, sedatives, antiinflammatory agents, and corticosteroids.

C. Lumbar disc herniation most often occurs at the L4 to L5 or L5 to S1 interspace.

1. Herniation produces muscle weakness, sensory deficits, and diminished tendon reflexes.
2. The client experiences pain and muscle spasms in the lower back, with radiation of the pain into one hip and down the leg (sciatica).
3. Pain is relieved by bed rest and aggravated by movement, lifting, straining, and coughing.
4. Interventions
   - **a.** Conservative management is indicated unless neurological deterioration or bowel and bladder dysfunction occurs.
   - **b.** Apply heat to decrease muscle spasms, and apply ice to decrease inflammation and swelling.
   - **c.** Instruct the client to sleep on the side, with the knees and hips flexed, and place a pillow between the legs.
   - **d.** Apply pelvic traction as prescribed to relieve muscle spasms and decrease pain.
   - **e.** Begin progressive ambulation as inflammation, edema, and pain subside.
5. Client education related to lumbar disc conditions
   - **a.** Instruct the client in the use of prescribed medications such as analgesics, muscle relaxants, antiinflammatory agents, or corticosteroids.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

BOX 61.4 Types of Disc Surgery

Discectomy: Removal of herniated disc tissue and related matter
Discectomy with Fusion: Fusion of vertebrae with bone graft
Laminectomy: Excision of part of the vertebrae (lamina) to remove the disc
Laminotomy: Division of the lamina of a vertebra

b. Instruct the client about application techniques for corsets or braces to maintain immobilization and proper spine alignment.
c. Instruct the client in correct posture while sitting, standing, walking, and working.
d. Instruct the client in the correct technique to use when lifting objects such as bending the knees, maintaining a straight back, and avoiding lifting objects above the elbow level.
e. Instruct in a weight control program as prescribed.
f. Instruct the client in an exercise program to strengthen back and abdominal muscles as prescribed.

D. Disc surgery is used when spinal cord compression is suspected or symptoms do not respond to conservative treatment; minimally invasive techniques may be prescribed (Box 61.4).

1. Postoperative interventions: Cervical disc
a. Monitor for respiratory difficulty from inflammation or hematoma.
b. Encourage coughing, deep breathing, and early ambulation as prescribed.
c. Monitor for hoarseness and inability to cough effectively, because this may indicate laryngeal nerve damage.
d. Use throat sprays or lozenges for sore throat, avoiding anesthetic lozenges that may numb the throat and increase choking risks.
e. Assess the surgical dressing; monitor the surgical wound for infection, swelling, redness, drainage, or pain; and manage surgical drains accordingly.
f. Provide a soft diet if the client complains of dysphagia.
g. Monitor for sudden return of radicular pain, which may indicate cervical spine instability.

2. Postoperative interventions: Lumbar disc
a. Assess the surgical dressing, monitoring for wound drainage and bleeding and monitoring surgical drains accordingly.
b. Monitor lower extremities for sensation, movement, color, temperature, and paresthesia.
c. Monitor for urinary retention, paralytic ileus, and constipation, which can result from decreased movement, opioid administration, or spinal cord compression.
d. Prevent constipation by encouraging a high-fiber diet, increased fluid intake, and stool softeners as prescribed.
e. Administer opioids and sedatives as prescribed to relieve pain and anxiety.
f. Assist and instruct the client to use a prescribed back brace or corset and to wear cotton underwear to prevent skin irritation.

3. Postoperative lumbar disc positioning
a. In the immediate postoperative period, the client may be expected to lie supine or have other activity restrictions, depending on the specific surgical intervention.
b. Instruct the client to avoid spinal flexion or twisting, noting that the spine should be kept aligned.
c. Instruct the client to minimize sitting, which may place a strain on the surgical site.
d. When the client is lying supine, place a pillow under the neck and slightly flex the knees.
e. Avoid extreme hip flexion when lying on the side.

Following disc surgery, instruct the client in correct logrolling techniques for turning and repositioning and for getting out of bed.

XIII. Amputation of a Lower Extremity

A. Description
1. Amputation (Fig. 61.6) is the surgical removal of a limb or part of the limb.
2. Complications include hemorrhage, infection, phantom limb sensation and pain, neuroma, and flexion contractures.

B. Postoperative interventions
1. Monitor for signs of complications.
2. Mark bleeding and drainage on the dressing if it occurs.
3. Evaluate for phantom limb sensation and pain; explain sensation and pain to the client, and medicate the client as prescribed.
4. Phantom limb pain can be a debilitating symptom following amputation. Mirror therapy with the assistance of a trained therapist can be helpful in controlling these symptoms.
5. To prevent hip flexion contractures, do not elevate the residual limb on a pillow.
6. First 24 hours: Elevate the foot of the bed to reduce edema; then keep the bed flat to prevent hip flexion contractures, if prescribed by the PHCP.
7. After 24 to 48 hours postoperatively, position the client prone to stretch the muscles and prevent hip flexion contractures, if prescribed.

Telegram & Insta: NCLEX_RN_Edu

Telegram & Insta: NCLEX_RN_Edu

8. Maintain surgical application of dressing, elastic compression wrap, or elastic stump (residual limb) shrinker as prescribed to reduce swelling, minimize pain, and mold the residual limb in preparation for prosthesis (Fig. 61.7)
9. As prescribed, wash the residual limb with mild soap and water and dry completely.
10. Massage the skin toward the suture line, if prescribed, to mobilize scar tissue and prevent its adherence to underlying bone.
11. Prepare for the prosthesis and instruct the client in progressive resistive techniques by gently pushing the residual limb against pillows and progressing to firmer surfaces.
12. Encourage verbalization regarding loss of the body part, and assist the client to identify coping mechanisms to deal with the loss. Support groups such as the Amputee Coalition can be very helpful in coping with the loss of the limb.

C. Interventions for below-knee amputation
1. Prevent edema.
2. Do not allow the residual limb to hang over the edge of the bed.
3. Discourage long periods of sitting to lessen complications of knee flexion.
4. Place the client in a prone position throughout the day as prescribed by the PHCP.

D. Interventions for above-knee amputation
1. Prevent internal or external rotation of the limb.
2. Place a sandbag, rolled towel, or trochanter roll along the outside of the thigh to prevent external rotation.
3. Place the client in a prone position throughout the day as prescribed by the PHCP.

E. Rehabilitation
1. Instruct the client in the use of a mobility aid such as crutches or a walker.
2. Prepare the residual limb for a prosthesis.
3. Prepare the client for fitting of the residual limb for a prosthesis.
4. Instruct the client in exercises to maintain range of motion and upper body strengthening.
5. Provide psychosocial support to the client.

F. Traumatic amputation: Emergency care (see Clinical Judgment: Take Action Box)

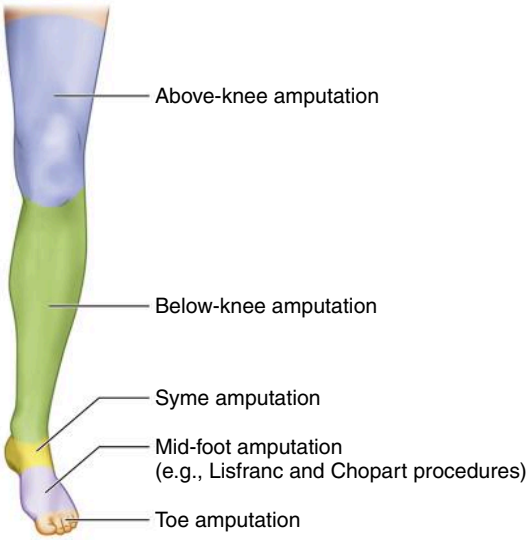

FIG. 61.6 Common levels of lower extremity amputation.

CLINICAL JUDGMENT: TAKE ACTION

The nurse employed in an industrial plant is called to an accident site in the plant in which an employee amputated an index finger on an electric saw. The nurse takes the following actions:

- Obtains emergency medical assistance (calls 911)
- Stays with the victim
- Checks the amputation site and applies direct pressure with gauze or cloth. (Do not remove applied pressure dressing to prevent dislodgment of a formed clot.)
- Elevates the extremity above heart level
- If a finger (or fingers) was amputated, places it in a watertight, sealed plastic bag; places the bag in ice water (not directly on ice); and transports the bag to the emergency department with the victim

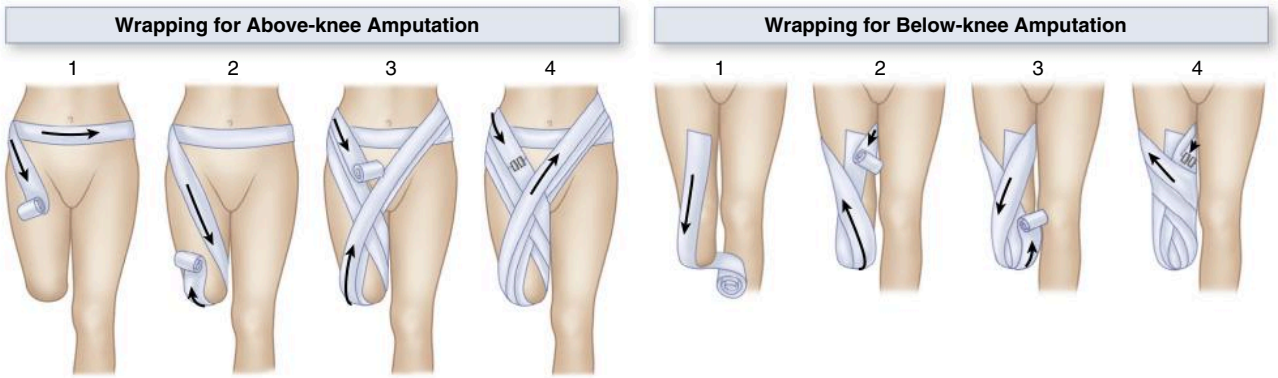

FIG. 61.7 A common method of wrapping a residual limb. *Left*, Wrapping for above-knee amputation. *Right*, Wrapping for below-knee amputation.

XIV. Rheumatoid Arthritis

A. Description

1. Rheumatoid arthritis is a chronic systemic inflammatory disease (immune complex disorder); the cause may be related to a combination of environmental and genetic factors.
2. Rheumatoid arthritis leads to destruction of connective tissue and synovial membrane within the joints.
3. Rheumatoid arthritis weakens the joint, leading to dislocation and permanent deformity of the joint.
4. Pannus forms at the junction of synovial tissue and articular cartilage and projects into the joint cavity, causing necrosis.
5. Exacerbations of disease manifestations occur during periods of physical or emotional stress and fatigue.
6. Vasculitis can impede blood flow, leading to organ or organ system malfunction and failure caused by tissue ischemia.

B. Assessment

1. Inflammation, tenderness, and stiffness of the joints
2. Moderate to severe pain, with morning stiffness lasting longer than 30 minutes
3. Joint deformities, muscle atrophy, and decreased range of motion in affected joints
4. Spongy, soft feeling in the joints
5. Low-grade temperature, fatigue, and weakness
6. Anorexia, weight loss, and anemia
7. Elevated ESR and positive rheumatoid factor
8. Radiographic study showing joint deterioration
9. Synovial tissue biopsy reveals inflammation.

C. Rheumatoid factor

1. Blood test used to assist in diagnosing rheumatoid arthritis
2. Reference interval: Negative or less than 60 IU/mL

D. Medications: Combination of pharmacological therapies includes NSAIDs, disease-modifying antirheumatic drugs (DMARDs), and glucocorticoids

E. Physical mobility

1. Preserve joint function.
2. Provide range-of-motion exercises to maintain joint motion and muscle strengthening.
3. Balance rest and activity.
4. Splints may be used during acute inflammation to prevent deformity.
5. Prevent flexion contractures.
6. Apply heat or cold therapy as prescribed to joints.
7. Apply paraffin baths and massage as prescribed.
8. Encourage consistency with exercise program.
9. Use joint-protecting devices.
10. Avoid weight bearing on inflamed joints.

BOX 61.5 Client Education for Rheumatoid Arthritis and Degenerative Joint Disease

- Assist the client to identify and correct safety hazards in the home.
- Instruct the client in the correct use of assistive or adaptive devices.
- Instruct the client in energy conservation measures.
- Review the prescribed exercise program.
- Instruct the client to sit in a chair with a high, straight back.
- Instruct the client to use only a small pillow when lying down.
- Instruct the client in measures to protect the joints.
- Instruct the client regarding the prescribed medications.
- Stress the importance of follow-up visits with the primary health care provider.

F. Self-care (Box 61.5)

1. Assess the need for assistive devices such as raised toilet seats, self-rising chairs, wheelchairs, and scooters to facilitate mobility.
2. Work with an occupational therapist or PHCP to obtain assistive or adaptive devices.
3. Instruct the client in alternative strategies for providing activities of daily living.

G. Fatigue

1. Identify factors that may contribute to fatigue.
2. Monitor for signs of anemia, and administer iron, folic acid, and vitamins as prescribed.
3. Monitor for medication-related blood loss by testing the stool for occult blood.
4. Instruct the client in measures to conserve energy, such as the pacing of activities and obtaining assistance when possible.

H. Disturbed body image

1. Assess the client's reaction to the body change.
2. Encourage the client to verbalize feelings.
3. Assist the client with self-care activities and grooming.
4. Encourage the client to get dressed daily and to wear street clothes.

I. Surgical interventions

1. Synovectomy: Surgical removal of the synovia to help maintain joint function
2. Arthrodesis: Bony fusion of a joint to regain some mobility
3. Joint replacement (arthroplasty): Surgical replacement of diseased joints with artificial joints; performed to restore motion to a joint and function to the muscles, ligaments, and other soft tissue structures that control a joint

XV. Osteoarthritis (Degenerative Joint Disease)

A. Description

1. Osteoarthritis is marked by progressive deterioration of the articular cartilage.
